Mean  $\pm$  s.e.m. from five experiments. Numbers in parentheses signify the number of successful microelectrode impalements.  $\psi_{cs}$  is basolateral membrane potential calculated from  $\psi_{ms} = \psi_{mc} + \psi_{cs}$ . The ratio of mucosal to basolateral membrane resistance  $(R_m/R_s)$ , the voltage divider ratio) was calculated from  $\Delta\psi_{mc}$  and  $\Delta\psi_{ms}$ , corrected for solution resistance, measured during application of 100- $\mu s$  current pulses <sup>6.10</sup>. Intracellular K<sup>+</sup> activity,  $a_{K}^+$ , was measured by K<sup>+</sup>-selective microelectrodes fabricated with Corning 47715 K<sup>+</sup> liquid ion exchanger by methods described <sup>11</sup>. Calibration plots in KCl standard solutions yielded an average slope of  $56.2 \pm 2.3$  mV per decade K<sup>+</sup> for 18 electrodes. Average values after  $10^{-3}$  M 8-Br-cyclic AMP were recorded at peak resistance, 30-75 min after its addition to the mucosal bath. Values for the recovery period were recorded within 15 min after removal of 8-Br-cyclic AMP. Peak values are significantly different (at least P < 0.05 by paired t-test) from control and recovery, except  $\psi_{cs}$  with respect to control.

Table 2 Morphometrical analysis of tight junctions

Condition	n	No. of horizontal strands	Linear density of horizontal strands (strands per µm)	Tight junction depth (μm)
Control	102	$8.0 \pm 0.2$	$16.1 \pm 0.5$	$0.56 \pm 0.02$
8-Br-Cyclic AMP (5 min)	43	$8.0\pm0.3$	$14.9\pm0.6$	$0.56\pm0.02$
8-Br-cyclic AMP (peak response)	65	$10.4 \pm 0.5$	$14.0 \pm 0.6$	$0.79 \pm 0.04$
Recovery	60	$8.9\pm0.3$	$14.8\pm0.5$	$0.62 \pm 0.02$

Values are mean ± s.e.m.; n is the number of grid lines drawn perpendicular to the most luminal junctional strand at 0.5-cm intervals on electron micrographs (×60,000). The average frequency of intersection of strands with grid lines determines the number of horizontal strands. Tight junction depth is the mean distance from the most luminal to most abluminal strand. 10<sup>-3</sup> M 8-Br-cyclic AMP was used in all experiments. All changes measured at peak response were significantly different from control and recovery (at least P<0.05 by unpaired t-test), except for the change in linear density with respect to recovery. Cyclic AMP induces a reversible longitudinal expansion of the fibrillar

the other hand, reduction of dilution potentials by cyclic AMP may simply reflect a change in dimensions of a normally cationselective channel.

Cyclic AMP has additional effects on cell membrane transport in this epithelium. 8-Br-cyclic AMP may increase Na+ conductance of the mucosal membrane, as demonstrated by the depolarization of  $\psi_{mc}$  and decreased ratio of mucosal to basolateral membrane resistance. Assuming no change in Rs, we calculate that mucosal membrane conductance increased 25fold. This is consistent with our observation that  $\Delta \psi_{\mathrm{mc}}$  virtually disappeared after exposure of the mucosal surface to 8-Br-cyclic AMP. Depolarization of  $\psi_{\rm mc}$  (and  $\psi_{\rm cs}$ ) and an increase in  $\psi_{\rm ms}$ with increased mucosa to serosa Na flux (and Isc) have been observed in Necturus gallbladder exposed to the antibiotic

Fig. 2 Freeze-fracture of gallbladder epithelium fixed at peak response (10<sup>-3</sup> M 8-Br-cyclic AMP). Note the increased number of grooves below the meshwork. Microvilli (MV) are labelled (×45,000). In control gallbladders fixed while bathed in amphibian Ringer's solution, strands form a regular meshwork. Occasionally an abluminal strand will extend down from this meshwork (see ref. 7).

amphotericin B, a drug thought to increase mucosal membrane conductance to cations4.5. However, increased mucosal membrane conductance cannot account for the observed decrease in NaCl dilution potentials or increased R, which require an independent effect on tight junction conductance. An electrical circuit model of Necturus gallbladder epithelium predicts that an increase in the shunt pathway resistance alone will depolarize  $\psi_{mc}^{3}$ . However, this model also predicts a hyperpolarization of the  $\psi_{cs}$  in these conditions rather than the 4-mV depolarization observed here. The gradual decrease in  $a_{K^+}$  after mucosal exposure to cyclic AMP is consistent with a change in cell membrane permeability to K+ or may result from the observed cell membrane depolarization. Thus, intracellular electrolyte shifts and/or changes in cell membrane permeability may account for our failure to observe the predicted hyperpolarization of  $\psi_{cs}$ .

The exact mechanism of cyclic AMP modulation of tight junctional permeability is not defined. Plant cytokinins behave electrophysiologically like a phosphodiesterase inhibitor while altering microfilament morphology7. As cyclic AMP reacts with the cytoskeleton in other cell systems, it may have a specific role in the orientation of tight junctional intramembranous strands, thereby regulating paracellular ion flow. Uncertainties as to the nature of the transjunctional ionic pathway restrict speculation on structure-function correlations. However, in a simple conductor, resistance is directly proportional to length and in these experiments resistance increased ~50% while junctional depth increased ~40%. Cyclic AMP may not affect all leaky epithelia in the same way; indeed, in mammalian kidney proximal tubule it increases transepithelial 14C-sucrose flux8, while in rabbit ileum it increases transepithelial electrical resistance9

## Increase in faecal nitrosamines in Japanese individuals given a Western diet

Kunio Suzuki & Tomotari Mitsuoka

Animal Physiology Laboratory, The Institute of Physical and Chemical Research, Wako-shi, Saitama 351, Japan

Colon cancer is prevalent in North America and Western Europe, but has a low incidence in Japan<sup>1,2</sup>. Epidemiology suggests that a high intake of animal fat<sup>3,4</sup> and protein<sup>5,6</sup>, especially beef<sup>7,8</sup>, is associated with colon carcinogenesis. Numerous hypotheses have been proposed to account for the relationship between these diets<sup>9-13</sup>, but experimental support for them is unconvincing. The specific carcinogen involved in cancer of the large bowel remains to be identified experimentally. Bruce and co-workers14 showed that several volatile nitrosamines were present in normal human faeces and suggested that these were produced endogenously in the lower intestine but they subsequently negated this hypothesis 15. We demonstrate here that the levels of volatile nitrosamines in human faeces are markedly increased in Japanese individuals given a Westernstyle diet, but decreased by a typical Japanese diet.

We studied six healthy Japanese male volunteers from our laboratory (aged 27-39 yr) who were not receiving medical treatment during this study. Three of the subjects were given, in order: (1) a typical Japanese diet for 4 days; (2) a mixed Japanese diet for 3 days; (3) a balanced Western-style diet for 8 days and then a typical Japanese diet for 6 days. Four of the subjects were given, in order, a long-term mixed Japanese diet followed by a high-fat, high-meat diet for 4 days. These diets are shown in Table 1. The typical Japanese diet consists of boiled rice and side dishes of fish and vegetables. This diet provided ~2.0 kcal, 15% protein (mostly cereal protein), 20% fat, 65% carbohydrate and 75 mg vitamin C. In the case of the balanced Western-style diet, the staple food is meat, with side dishes of bread and vegetables. For breakfast, orange juice was replaced by vegetables to provide nitrate intake. This diet provided

	Table 1 Composition of diets					
	Food item	Amount				
Typical Japa		1				
Breakfast	Rice, boiled	1 cup				
	Soup, containing bean paste (miso) and bean curd	1 cup				
	(tofu), vegetable or seaweed Egg, raw or cooked	1				
	Seaweed (dried laver (nori)) and/or vegetable	5 pieces				
	(Chinese cabbage, spinach, etc.), boiled	50 g				
	Pickled vegetable	Little				
	Japanese green tea	1/2 cup				
Lunch	Rice, boiled, or noodles	2 cups 1 cup				
	Soup (similar to breakfast) Fish, broiled	70 g				
	Vegetable (same as breakfast)	50 g				
	Pickled vegetable	Little				
	Fruit (Japanese mandarin)					
	Japanese green tea	1 cup				
Dinner	Rice, boiled	2 cups 1 cup				
	Soup (similar to breakfast)	70 g				
	Fish, broiled, boiled, fried or raw Cooked vegetables (4-5 kinds of raddish, carrot,	1 cup				
	burdock, onion, potato and mushroom (shiitake),					
	added fish paste or chicken)					
	Pickled vegetable					
	Fruit (apple or Japanese mandarin)	1 /2				
	Japanese green tea	1/2 cup				
Balanced W	/estern-style diet					
Breakfast	Egg and bacon or ham, fried	150 g				
	Bread and butter	1 slice 100 g				
	Vegetables (1-2 kinds of lettuce, celery and spinach),	100 g

Variety of items from Western, Chinese and typical Japanese diets

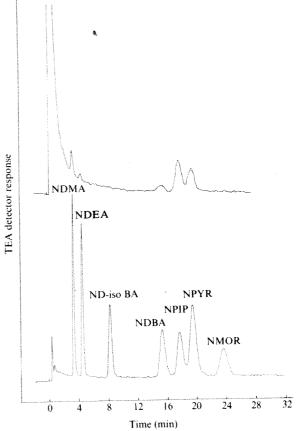

Fig. 1 GLC-TEA (thermal energy analyser) chromatograms obtained for 10 µl dichloromethane extracts of human faeces (upper part) and a standard mixture of volatile nitrosamines (lower part). Fresh faeces were immediately homogenized and weighed: 5 g faecal samples were homogenized in a Teflon homogenizer with 8 g sodium chloride and 20 ml 2 M dosium hydroxide. The samples were then transferred to two 50-ml centrifugation tubes having ground stoppers, and extracted three times with 30 ml dichloromethane (absorbancy analysis reagent; Dōjin) using a shaker. The dichloromethane was separated by centrifugation at 3,000 r.p.m. for 10 min. The extracts were washed with a small volume of distilled water in a separating funnel, and dried over anhydrous sodium sulphate. Sodium sulphate was then washed three times with a small volume of dichloromethane. The combined extracts were evaporated to 0.5 ml in a Kuderna-Danish concentrator at 33 °C for ~1 h. A gas-liquid chromatograph connected to a thermal energy analyser (model TEA-502, Thermo Electron) was used to detect nitrosamines. Glass tubing (2 m× 3 mm) packed with 25% PEG 6,000 on chromosorb W, 60-80 mesh was used in a single-column isothermal gas chromatograph. The carrier gas was argon (flow rate 50 ml min<sup>-1</sup>) and the column temperature was 160 °C. TEA attenuation was ×4. The recovery rates of NDMA, NDEA, NDBA, NPIP, NPYR and N-nitrosomorpholine (NMOR) (added to the faeces at a concentration of 1 mg per kg) were 69, 75, 78, 81, 82 and 81%, respectively. The detection limit was in the range 0.2-0.5 µg per kg.

~2.8 kcal, 25% protein (mostly animal protein), 55% fat, 20% carbohydrate and 70 mg vitamin C. The mixed Japanese diet consists of various food items, including those typical of Western, Chinese and Japanese diets, and is popular among contemporary Japanese. This diet provided ~2.4 kcal, 20% protein, 30% fat, 50% carbohydrate and 90 mg vitamin C. The high-fat, high-meat diet is mostly animal fat and meat with small amounts of bread and vegetables, which provides ~3.0 kcal, 30% protein, 65% fat, 5% carbohydrate and 15 mg vitamin C. Nitrate contents of these diets were estimated according to Walker<sup>16</sup> and Yanagihara et al. To be: typical Japanese diet, 450 mg; balanced Western-style diet, 360 mg; mixed Japanese diet, 250 mg; and high-fat, high-meat diet, 50 mg.

Several volatile nitrosamines were detected in normal human faeces (Fig. 1). The five peaks were identified as N-nitroso-

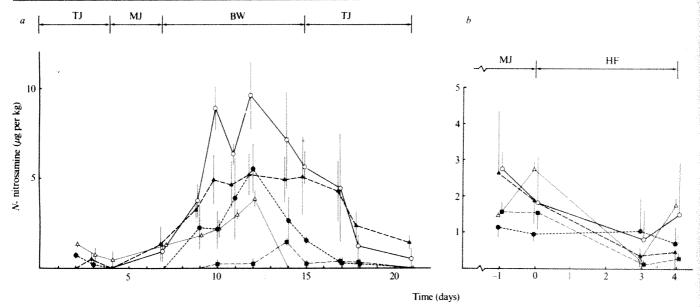

Fig. 2 Changes in levels of volatile nitrosamines in human faeces from individuals on Japanese and Western-style diets (a), and mixed Japanese (MJ) and high-fat, high-meat (HF) diets (b). ●, NDMA; ■, NDEA; △, NDBA; ○, NPIP; ▲, NPYR. TJ, typical Japanese diet; BW, balanced Western-style diet. Values represent the mean ± s.e.m. for three or four subjects.

dimethylamine (NDMA), N-nitrosodiethylamine (NDEA), Nnitrosodibutylamine (NDBA), N-nitrosopiperidine (NPIP) and N-nitrosopyrrolidine (NPYR) by comparison with standards. A control experiment showed that the reagents and glassware used in the analysis did not contaminate the volatile nitrosamines, and that the addition of 1 M sulphamic acid (which decomposes NO<sub>2</sub>), 50 mM ascorbic acid (which inhibits nitrosation of amines<sup>18</sup>) or 0.1 M sodium nitrite (a precursor of nitrosamines) to the faecal samples did not affect the yield of nitrosamines. Furthermore, we analysed the faecal samples immediately after collecting specimens. These experiments indicated that there was no artificial formation of nitrosamines during either the analysis<sup>15</sup> or storage<sup>19</sup>. To extract volatile nitrosamines from faeces using dichloromethane, the distribution ratio must be improved by salting out and alkalization of the faecal samples. Volatile nitrosamines in faeces may exist in a state which is difficult to extract, possibly because the nitrosamines are contained in undigested food, or bound chemically or physically to some compounds.

The changes in levels of volatile nitrosamines in faeces observed for the different diets are shown in Fig. 2. Each subject showed a similar pattern of nitrosamine levels. In the case of the typical Japanese diet, faeces contained NDMA, NDBA and NPYR at levels below 1.7 µg per kg. The amount of faecal nitrosamines detected varied from day to day. After 3 days on the mixed Japanese diet, NPIP appeared and the concentration of NPYR increased. In the case of the balanced Western-style diet, these nitrosamines increased in faeces markedly, particularly NPIP, which reached a maximum of 13.3 µg per kg. The maximum total amount of nitrosamines was 26.6 µg per kg. NDMA, NPIP and NPYR were detected constantly during the study period for the balanced Western-style diet, but no NDBA was detected on the latter days of the diet. After the change from the balanced Western-style diet to the typical Japanese diet, the levels of these nitrosamines in faeces were reduced but not rapidly. NDEA was detected at a maximum of only 1.8 µg per kg during this experimental period, and there was no clear change in amounts of NDEA with change in diet. On the other hand, these nitrosamines decreased in individuals when taken off the mixed Japanese diet and given the high-fat, high-meat diet (Fig. 2b).

These results suggest that volatile nitrosamines in faeces do not originate from nitrosamines formed in fat during cooking<sup>20,21</sup>, but are formed in the intestine from precursors contained both in meat and vegetables. N-nitrosamines may be formed from precursors in the intestine in the following way.

Nitrate, which is largely contained in vegetables<sup>16,17</sup>, is reduced to nitrite by oral or intestinal bacteria<sup>22,23</sup>. Amino acids and lipids, largely contained in meat, are decomposed to secondary amines by the intestinal bacteria<sup>24,25</sup>. Finally, N-nitrosamines are formed from nitrite and secondary amines by the intestinal bacteria in the neutral or weak alkaline conditions of, for example, the lower intestine 26.27. It is considered that the low levels of volatile nitrosamines found in faeces of individuals given the typical Japanese diet or the high-fat, high-meat diet are due to the low amounts of amino acids and lipids in the former diet and the low amounts of nitrate in latter. Sufficient quantities of nitrate and amino acid or lipid, such as in the balanced Western-style diet, will be necessary for the formation of nitrosamines in the intestine. It is known that vitamin C inhibits nitrosation of amines<sup>18</sup>. The vitamin C content in the balanced Western-style diet was nutritionally sufficient, but was insufficient to inhibit nitrosation. The average level of total volatile nitrosamines in faeces in the case of the nutritionally balanced Western-style diet was 10 times that in faeces from those given the typical Japanese diet. This may have strong implications for the aetiology of colon cancer. It is possible that N-nitrosamines in the faeces are responsible for many other kinds of cancer, for example, breast and prostate, as these show the same epidemiological pattern as colon cancer<sup>1,2</sup>. Further investigation of the carcinogenicity of N-nitrosamines, and the inhibition of N-nitrosamine formation in the intestine by the control of diets or intestinal bacteria is needed.

#### Anti-PGE antibodies inhibit in vivo development of cell-mediated immunity

#### J. Mertin & A. Stackpoole

Transplantation Biology Section, Clinical Research Centre, Watford Road, Harrow, Middlesex HA1 3UJ, UK

Prostaglandins have been implicated in the regulation of humoral and cell-mediated (CMI) immunity, but little is known about their precise mode of action; published data indicate both enhancing and suppressing activity of these substances<sup>1</sup>-E-type prostaglandins (PGEs) act as extracellular modulators of the function of T lymphocytes<sup>5,6</sup> and there may be differences in the sensitivity of different T-cell subpopulations to this modulation<sup>7-9</sup>. As most studies have used in vitro test systems, it is unknown whether prostaglandins have the same effects in vivo4. We have therefore examined the role of PGEs in CMI in vivo. Prostaglandins are derived from essential fatty acids (EFA) via the cyclooxygenase system, and inhibition of this pathway by aspirin or indomethacin<sup>10,11</sup> has been widely used to study prostaglandin effects. However, the usefulness of these substances in vivo is restricted by their toxicity and limitations in their selective action<sup>12,13</sup>. An alternative is to use anti-prostaglandin antibodies, which antagonize F- and E-type prostaglandins in experimental animals 14,15 and prevent PGI<sub>2</sub> from inhibiting ADP-induced platelet aggregation16. We report here that anti-PGE antisera significantly suppressed experimental allergic encephalomyelitis (EAE) in rats and prevented the generation of host-versus-graft (HvG) and graft-versus-host (GvH) reactions in mice, suggesting that PGEs are important mediators not only of in vitro induction of CMI responses<sup>8,9</sup> but also of the early phase of CMI in vivo.

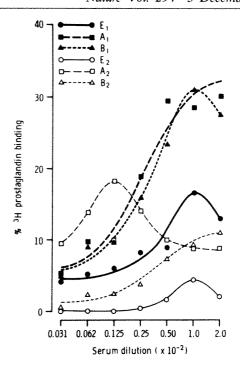

Fig. 1 Radioimmunoassay of an anti-PGE<sub>1</sub> antiserum (APS) raised in Lewis rats by s.c. injection of 0.2 mg of a PGE<sub>1</sub>-BSA conjugate emulsified in complete Freund's adjuvant (CFA) followed by two injections, at monthly intervals, of 0.1 mg of conjugate in CFA. Serum was collected on day 10 after the third inoculation of antigen and thereafter at monthly intervals, 10-12 days after further boosting with  $0.1\,\mathrm{mg}$  of conjugate. A similar protocol was used for the production of APS in rabbits and mice with the doses of antigen adjusted to the different body weights: rabbits received 2.0 and 1.0 mg and mice 0.02 and 0.01 mg of the conjugate. Control sera were raised by the same method but using injections of BSA in CFA only. Anti-PG activity was tested by radioimmunoassay. Serial dilutions of APS were carried out in V-shaped microtitre plates (Sterilin). 3H-labelled prostaglandins  $E_1$ ,  $A_1$ ,  $B_1$  and  $E_2$ ,  $A_2$  and  $B_2$  (specific activity 50 Ci mmol<sup>-1</sup>; Amersham) were added to the wells at an activity of  $\sim 12,000$  counts per min. After incubation for 1 h at 37 °C, 20 µl of anti-rat IgG (H+L; Nordic Immunology Laboratories, UK) and 15  $\mu$ l of normal rat serum (diluted 1:100) were added. After further incubation for 16 h at 4 °C the plates were centrifuged (500g at 4 °C for 30 min). The supernatants were decanted and the precipitates dissolved in 0.2 ml of 0.1M NaOH and transferred to 2 ml NE260 scintillation fluid (Nuclear Enterprises), Radioactivity was measured in a liquid scintillation counter. All tests were carried out in triplicate. A background activity of 5-6% was measured in the control serum as well as in normal rat serum, and this activity was subtracted from that found for APS.

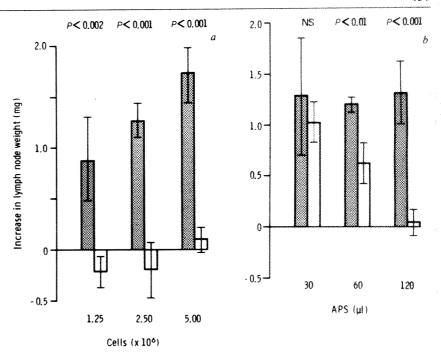

Anti-prostaglandin antiserum (APS) was raised by repeated subcutaneous (s.c.) injections in Lewis rats, NZW rabbits or CBA mice of a conjugate of PGE<sub>1</sub> and bovine serum albumin (BSA) emulsified in complete Freund's adjuvant<sup>17,18</sup>. Antiprostaglandin activity of these sera compared well with those reported elsewhere 16-19. Figure 1 shows the anti-PGE<sub>1</sub> activity

Table 1 Suppression of EAE in Lewis rats by antisera containing antibodies to PGEs

		No. of rats per			EAI	E prevalence on	various days af	ter antigen inoc	ulation	
Expt	Group	group	Treatment	Day 13	Day 15	Day 17	Day 19	Day 21	Day 23	Day 29
1	а	6	Control serum	0 (0)	2 (3)	6 (20)	6 (17)	6 (17)	6 (18)	6 (17)
	b	6	APS	0 (0)	0 (0)	0 (0)	0 (0)	1 (5)	2 (8)	2 (8)
2	а	8	Control serum	2 (2)	5 (7)	7 (20)	8 (34)	8 (30)	6 (22)	4 (8)
	ь	8	APS	0 (0)	0 (0)	0 (0)	1 (1)	1 (6)	1 (6)	2 (8)
Difference	in EAE prev	alence between	groups $a$ and $b^*$	NS	$P \leq 0.01$	P < 0.002	P < 0.002	P < 0.002	P < 0.002	NS

EAE was produced by s.c. injection of guinea pig brain stem and spinal cord material emulsified in complete Freund's adjuvant<sup>21,22</sup>, and severity of clinical disease scored in the range 0 (= no disease) to 8 (= death due to EAE)<sup>21,22</sup>. The batches of control serum and APS used were raised in Lewis rats (expt 1) or NZW rabbits (expt 2). APS or control serum (0.25-0.30 ml) was injected three times weekly between day 0 and day 21 (expt 1) or day 23 (expt 2). After discontinuation of the treatment, a few more animals in the two APS groups developed EAE, but no further increase in disease prevalence was observed after day 29 (for a further observation period of  $\sim$ 2 months). EAE prevalence = no. of rats per group showing clinical signs of EAE at any one of the days indicated; the sum of clinical scores per group is given in parentheses Significance by Fisher's exact test for experiments 1 and 2 pooled. NS, not sigificant.

Fig. 2 The effect of APS on HvG reaction in CBA mice. CBA mice were inoculated in the left footpad with irradiated (2,000 rad) spleen cells of A strain mice, and the right footpad was injected with irradiated spleen cells from CBA mice. The extent of the resulting reactions was determined by measuring the increase in weight of the left popliteal lymph node over the weight of the right node. a The weights of the popliteal lymph nodes were measured on day 3 after inoculation of the mice with various concentrations of irradiated spleen cells. APS or control serum (derived from CBA mice) was injected s.c. into the nuchal region at a dose of 30 µl per day. The first injection was on day 0, immediately after inoculation of the cells (time 0), and was followed by further injections on days 1 and 2. b, APS or control serum (derived from CBA mice) was given as a single s.c. injection on day 0 immediately after footpad inoculation of CBA mice with a fixed number (5×106) of spleen cells. Columns represent the mean increase in weight (±s.d.) of the left popliteal lymph nodes over the weight of the right popliteal nodes in groups of six mice. Shaded and open columns represent treatment with control serum and APS, respectively. The differences between control groups and APS-treated animals were assessed using Student's t-test. NS, not significant.

of a batch of APS used to treat EAE. Dehydration and rearrangement of double bonds can result in the conversion of some of the PGE<sub>1</sub> into PGA<sub>1</sub> and PGB<sub>1</sub> during the conjugation of PGE<sub>1</sub> to BSA. A similar conversion may also occur after injection of the conjugate, due to the action of the recipients' dehydrating and isomerizing enzymes<sup>20</sup>. Thus, not only did we detect anti-PGE<sub>1</sub> activity but also activities against PGA<sub>1</sub> and PGB<sub>1</sub>, as well as cross-reactivity with PGE<sub>2</sub> and its respective derivatives (Fig. 1). As we were less successful in raising APS by injection of a PGE<sub>2</sub>-BSA conjugate, all experiments reported here used only serum produced by injections of PGE<sub>1</sub>-BSA. Control sera were raised by injection of BSA emulsified in complete Freund's adjuvant, using the same method as for production of anti-PG antiserum.

We first tested the effect of APS on EAE. This CMI disease was induced in Lewis rats and its activity determined as described previously<sup>21,22</sup>. Treatment with s.c. injections of APS from the day of antigen inoculation (day 0) up to days 21-23 suppressed EAE (see Table 1). Not only were there significantly fewer animals developing clinical signs of EAE but also onset of the disease was delayed in the APS-treated groups.

As the use of EAE in rats was too complicated for investigating the dose-response effect of APS and its inhibitory action in relation to the time of administration, we used mice in further experiments. HvG and GvH reactions induced by injection of allogeneic cells or cells of parental strain animals were measured in a lymph node assay system. We found that APS treatment significantly suppressed both HvG and GvH reactions in mice. Injections s.c. of 30 µl APS per day, from day 0 to day 2 after challenge of CBA mice with A strain spleen cells almost completely inhibited the HvG reaction (Fig. 2a). The inhibitory effect of a single dose of APS given immediately after the injection of donor cells was dose dependent in HvG (Fig. 2b) as well as in GvH experiments (Fig. 3). GvH reactions were reduced to about half by 20-30 µl APS; 60 µl were needed to achieve a similar effect in HvG reactions. Studies of the effect of APS in relation to time of its administration showed that the sera were most effective during the first hours after challenge of the animals with donor cells (Fig. 4). This was most pronounced in HvG reactions: the inhibitory effect of a single dose of APS (120 µl) given at time 0 was much greater than the effect of APS given 6 h after the injection of donor cells. In GvH reactions an inhibitory effect was still observed when APS was administered as late as 24 h after cell injection. However, inhibition was again greatest during the first hours after the inoculation of parental strain cells.

PGEs have been found to inhibit mitogen-induced lymphocyte proliferation<sup>23-25</sup>, lymphocyte-mediated cytolysis<sup>26</sup> and the production of lymphokines<sup>5,6,27</sup>. Treatment in vivo with PGE<sub>1</sub> prevented development of anaemia and progression of nephritis in murine lupus erythematosus<sup>28,29</sup> and the development of hypersensitivity responses was reduced in mice<sup>30</sup>. Furthermore, PGE<sub>2</sub> restricted lymphocyte traffic through antigen-stimulated lymph nodes, possibly by modulating the interaction of the lymphocytes with adherent cells within the nodes<sup>31</sup>. In two recent studies in vitro<sup>8,9</sup>, PGEs affected the induction phase of one-way mixed lymphocyte reactions and development of lymphocyte cytotoxicity. Cell proliferation as well as cytotoxicity were enhanced when the cultures were treated with indomethacin, but the response was restored to normal by

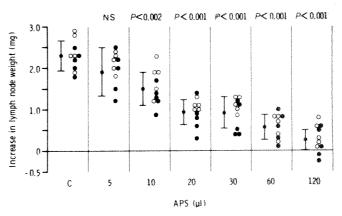

Fig. 3 Dose response of APS in a GvH reaction. (CBA×C57BL/10)F₁ mice received spleen cells from C57BL/10 mice in the left footpad and spleen cells from (CBA×C57BL/10)F₁ animals in the right. Various doses of APS were injected s.c. into the nuchal region on day 0, immediately after the footpad inoculation of 5×10<sup>6</sup> spleen cells. The weights of the popliteal lymph nodes were measured 4 days after inoculation of the cells. Data points show increase in weight of the left popliteal node in individual animals treated with APS or control serum (C) as derived from CBA mice (○) or NZW rabbits (●). Bars represent the mean increase in weight (±s.d.) per group. (For statistical evaluation see Fig. 2 legend.)

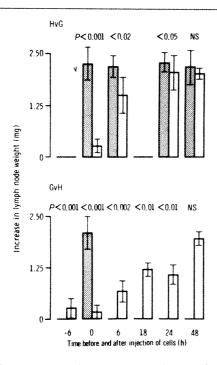

Fig. 4 The effect of a single dose of APS on HvG and GvH reactions in mice, in relation to the time of APS administration. Groups of CBA and (CBA×C57BL/10)F<sub>1</sub> mice (five per group) received footpad inoculations of  $5 \times 10^6$  donor spleen cells; APS was injected at different time intervals before or after cell inoculation. Lymph node weights were determined on day 3 (HvG) or day 4 (GvH) after cell inoculation. Columns represent the mean increase in weight (±s.d.) per group of the left popliteal lymph nodes in animals treated with APS (open columns) or control serum (shaded columns). (For statistical evaluation see Fig. 2 legend.)

adding PGE2 to the cultures. Thus, it was suggested that PGEs may be negative (that is, inhibiting) mediators of CMI development.

In contrast to these in vitro findings, our in vivo data indicate that PGE is required as a positive (augmentative) mediator substance during the induction phase of CMI. These contrasting results could be reconciled if the effect of prostaglandin was governed by a bell-shaped dose-response relationship. According to our hypothesis, low prostaglandin concentrations would be required to initiate or enhance the induction of CMI responses whereas high concentrations would inhibit this process. Anti-PG antibodies may be more effective than indomethacin in reducing the concentrations of active prostaglandin at the site of action and treatment with such antibodies might thus deprive the immunological microenvironment of agents required for the induction of immune responses.

Our results emphasize the potential importance of anti-PG antibodies as tools for elucidating the effects of different prostaglandins and other EFA derivatives on immune mechanisms. It might also be possible to use such antibodies to correct immunological disorders. However, a shortcoming of the APS used here is its polyvalent nature. Greater specificity could be achieved using monoclonal antibodies, and experiments to explore this possibility are in progress.

We thank Professor Sir Peter Medawar for helpful discussion and encouragement.

#### Identification of antigenic determinants unique to the surfaces of cells transformed by Epstein-Barr virus

#### Chris Kintner\* & Bill Sugden

The McArdle Laboratory for Cancer Research. University of Wisconsin, Madison, Wisconsin 53706, USA

Epstein-Barr virus (EBV) transforms human B lymphocytes in vitro and is associated with two human lymphoproliferative diseases, Burkitt's lymphoma and infectious mononucleosis. In contrast to the lymphoma, infectious mononucleosis is selflimiting and the finding by Svedmyr and Jondal of cytotoxic T lymphocytes specific for EBV-transformed cell lines in mononucleosis patients' blood during the acute phase suggests that this self-limitation results, in part, from the cell-mediated immune response of the host. These workers termed the structure expressed on EBV-transformed cells and which was recognized by specific, cytotoxic T cells, LYDMA (lymphocyte determined membrane antigen). It has also been shown that with appropriate education in culture, cytotoxic T cells from healthy donors specifically kill autochthonous, EBV-transformed cell lines2. These target cells generally do not produce virus and bear no virion-associated antigens. We have now isolated monoclonal antibodies which detect antigenic determinants unique to the surfaces of EBV-transformed cells but are not associated with virus production. Quantitative assays for these determinants indicate that they are expressed strongly on cells transformed in vitro by EBV but are expressed at intermediate or undetectable levels on cell lines established from patients with Burkitt's lymphoma. These antigenic determinants may be among those recognized by autochthonous, cytotoxic T cells specific for EBV-transformed cell lines, and if they are, their diminished expression on tumour-derived cells may reflect a selective advantage in vivo for those tumour cells.

Spleen cells from C57BL/6 or BALB/c mice immunized by repeated intraperitoneal injections of 107 cells of one clone of EBV-transformed human cells were used to generate hybridomas following the method of Kohler and Milstein3. A twostep screening was performed to select those hybridomas whose antibodies bound to an EBV-transformed cell clone different from that used for immunizations but not to primary T lymphocytes. Eighteen hybridomas which showed this specificity of binding were isolated, cloned at least three times and injected into pristane-primed mice to form ascites tumours.

The monoclonal antibodies from the 18 different ascitic fluids were first characterized by assaying for their binding to a panel

Present address: Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

Table 1 Binding of monoclonal antibodies to human cell lines

Binding	Description of cell line	Association with EBV	Ref.
Strongly positive	Five clones of cells transformed in vitro by EBV from three donors	+	10
	Four cell lines transformed in vivo and not associated with Burkitt's lymphoma: WI-L2, RPMI 1788, E.H. IV, CCRF-SB	+	11, 12, 13, 12
Intermediate	Four cell lines established from four Burkitt's lymphoma patients: B35M, B46M, AG876, Raji	+	12, 12, 14, 12
Negative	Three cell lines established from three Burkitt's lymphoma patients: EB-3, Daudi, P3HR-1	+	15, 12, 16
regative	One EBV-negative Burkitt's lymphoma cell line, BJA-B-1	····	16
	One acute lymphocytic B-cell line, BALL-1	regue	12
	One multiple myeloma cell line, RPMI 8226	***	12
	One lymphosarcoma B-cell line, U-698-M	-	12
	One acute lymphocytic T-cell line, CCRF-CEM	-	12
	One acute lymphocytic T-cell line, CCRF-HSB-2	***	12
	One erythroleukaemia cell line, K-562	need	12
	One chronic myelocytic non-B, non-T cell line, NALM-1	MARY	12
	One human fibroblast strain	2007	

The binding of the four monoclonal antibodies to human cell lines was measured with a sheep red blood cell (SRBC) rosette assay using ascites fluid prepared from each hybridoma and diluted from  $10^{-1}$  to  $10^{-6}$  in 10-fold increments<sup>17</sup>. Aliquots ( $50~\mu$ l) of each dilution were incubated with  $2\times10^5$  cells at  $4^{\circ}$ C in assay buffer: phosphate-buffered saline, 5.0% fetal calf serum and 0.4 mg ml<sup>-1</sup> pooled human  $\gamma$  globulin. After 0.5 h, cells were washed twice and pelleted with  $5\times10^7$  SRBC coupled to affinity-purified goat anti-mouse immunoglobulin. After 0.5 h, the cell pellets were resuspended in  $50~\mu$ l of assay buffer and viewed by light microscopy for rosette formation. The results obtained for binding were classified into three groups by the following criteria: strongly positive =90% of the test eells formed rosettes down to dilutions of  $10^{-4}$ - $10^{-5}$ ; intermediate binding =10-30% test cells formed rosettes down to dilutions of  $10^{-3}$ - $10^{-4}$ ; negative binding =10-rosettes formed at dilutions  $>10^{-1}$ .

of human cell lines. Four of these antibodies have the same specificities. The data in Table 1 indicate that only cell lines transformed by EBV bind these four monoclonal antibodies; cell lines transformed in vitro or those transformed in vivo but not associated with Burkitt's lymphoma bind them strongly; cell lines from patients with Burkitt's lymphoma bind them at intermediate or undetectable levels. Among the cell lines which also fail to bind these antibodies are four derived from B-cell tumours which are not associated with EBV.

Binding of these four antibodies to several of the lines listed in Table 1 was measured quantitatively using a fluorescence-activated cell sorter and the results showed that in identical conditions 85–97% of cells in the strongly positive populations bound the antibodies, compared with 10–30% and 2–5% of the intermediate and negative populations, respectively. In addition, 2–5% of the negative populations bound an anti-H-2K<sup>k</sup> monoclonal antibody which serves as a background for nonspecific binding in this assay. Among the fraction of cells scored as binding, the median fluorescent cell in the strongly positive populations bound five times as much label as did the median fluorescent cell in the intermediate populations. Monoclonal antibodies with the above binding specificity will be termed anti-EBVCS.

EBVCS determinants are not associated with virus production and are therefore different from the virus-associated cell-surface antigen, MA<sup>4</sup>. The cell line, P3HR1, in which ~5% of the cells permit viral maturation and express MA, does not express EBVCS determinants, nor does the B95-8 cell line in which 4-8% of the cells permit viral maturation and express MA. These two cell lines were negative for EBVCS determinants using both a rosetting assay and a direct immunofluorescence assay (Table 1 and unpublished data). In addition, clones of cells transformed *in vitro* by EBV in which fewer than 3 cells per 10<sup>5</sup> release virus per 24 h (ref. 5) are uniformly positive for expression of EBVCS (Table 1).

To determine whether EBVCS determinants are present on or can be induced in primary human lymphocytes, we have assayed for their expression on untreated lymphocytes and on lymphocytes exposed to EBV, concanavalin A (Con A) and pokeweed mitogen (PWM). Between 0.5 and 4% of freshly isolated human lymphocytes bind anti-EBVCS antibodies as well as an anti-H-2K<sup>k</sup> monoclonal antibody. Primary lymphocytes lose this initial background of binding after several days in culture. The data in Fig. 1 indicate that only lymphocytes exposed to EBV express EBVCS determinants, detectable within 48 h after infection. Neither blast transformation induced by Con A nor blast transformation and immunoglobulin secretion induced by PWM in lymphocytes<sup>6</sup> in the absence of

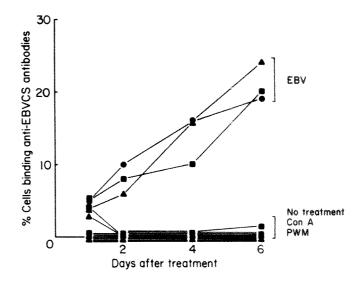

Fig. 1 Lymphocytes isolated from the peripheral blood of healthy donors were infected with the B95-8 strain of EBV at an MOI 1, or were treated with PWM and Con A at concentrations of  $10~\mu g\,ml^{-1}$  and  $2~\mu g\,ml^{-1}$ , respectively. All cells were cultured in RPMI 1640 medium + 10% fetal calf serum. On 1, 2, 4 and 6 days after treatment, a sample of cells from each culture was assayed for the binding of anti-EBVCS antibodies (IgG1A (A), IgG1B (■) and IgM (●)) using an indirect immunofluorescence assay. For each assay,  $4\times10^5$  cells were incubated at  $4\,^\circ\text{C}$  with a  $10^{-3}$  dilution of a hybridoma's ascites fluid in  $100\,\mu\text{l}$  of assay buffer (described in Table 1 legend). After 0.5 h, the cells were washed, incubated with fluorescein isothiocyanate (FITC)-labelled goat anti-mouse immunoglobulin at 4 °C for 0.5 h, washed again and dried on glass slides. Cells were fixed with methanol, counterstained and then scored under UV epifluorescence microscopy. Ascites fluid raised from an anti- $H-2K^k$  hybridoma was used to measure nonspecific binding. A cloned line of in vitro-transformed cells (THLB1) was included in each assay as a positive control and gave ≥90% fluorescent staining cells. For each point, 100-300 cells were counted and the data were expressed as the per cent of positive staining cells. The immunoglobulin subclass of the four anti-EBVCS antibodies was determined using FITCgoat anti-mouse IgG1, IgG2 and IgM. Although all four EBVCS antibodies vere used, results are given for the three which were isolated from separate fusions. The results for the fourth anti-EBVCS, which is an IgM antibody and isolated from the same fusion as the other IgM, are equivalent to those shown. The mitogenic response of primary lymphocytes to Con A and PWM treatment was established by measuring stimulation of DNA synthesis.  $10^6$  cells from each culture were pulsed with  $0.5\,\mu\text{Ci}^{-3}\text{H-thymidine}$ 1) in 1.0 ml for 24 h beginning on day 3. Cells were lysed and (50 Ci m mol incorporated <sup>3</sup>H-thymidine was determined by trichloroacetic acid precipitation. Fourfold more <sup>3</sup>H-thymidine was incorporated into the Con Aand EBV-treated cultures than into the untreated culture. The per cent of cells expressing EBNA in the untreated and EBV-infected cultures was assayed as published previously and was found to be 0.0% and 10%, respectively.

Table 2 EBNA-positive and EBVCS-positive cells form overlapping populations

Antibody used in assay	Unseparated lymphocytes (%)	T cells (%)	B cells (%)
Anti-EBNA	14	1.5	66
Anti-H-2K <sup>k</sup>	0	0	3.3
Anti-EBVCS-IgG1A	16	0.5	63
Anti-EBVCS-IgG1B	11	0.5	63
Anti-EBVCS-IgM	12	1	62

After 5 days in culture, a portion of EBV-infected primary lymphocytes was left unseparated and a portion was separated into T- and B-cell populations using Petri dishes coated with rabbit anti-human Fab antibodies8. These three populations of cells were scored for EBVCS determinants by indirect immunofluorescence as described in Fig. 1 legend and for EBNA by anti-complement immunofluorescence<sup>7</sup>, 100-300 cells were counted for each assay and the data expressed as the per cent of cells exhibiting immunofluorescence. THLB1 cells were included in each assay and ≥90% of the cells stained positively for both EBNA and EBVCS

EBV leads to detectable expression of EBVCS determinants. The observed association between transformation by EBV and expression of EBVCS determinants indicates that those infected cells which develop expression of EBNA7, the EBVinduced nuclear antigen, may also be those which express EBVCS. To test this prediction, primary lymphocytes were exposed to EBV, cultured for 5 days and a portion of the cells separated into immunoglobulin-positive and -negative populations by binding them to plastic dishes coated with rabbit anti-human Fab antibodies8. Assay of unseparated populations and the immunoglobulin-positive and -negative populations (Table 2) indicates that those cells which express EBVCS determinants are separated as B cells along with those which express EBNA and that the two antigen-expressing populations are overlapping and may be identical.

To identify the molecule(s) which carries the EBVCS determinants, cells were labelled with 125 I using lactoperoxidase, and immunoprecipitates of extracts of the labelled cells were resolved on polyacrylamide gels. The results depicted in Fig. 2 indicate that one of the two IgG class antibodies precipitates a polypeptide with an apparent molecular weight of 45,000 from only the EBVCS-positive cell line. Although this polypeptide is

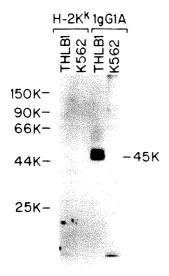

Fig. 2 Immunoprecipitations using monoclonal antibodies were carried out on lysates prepared from  $2\times10^7$  THLB1 (EBVCS positive) and  $2\times10^7$  K562 (EBVCS negative) cells labelled with <sup>125</sup>I and lactoperoxidase as described previously <sup>18</sup> with the following modification: 2.5  $\mu$ I of ascites fluid from either the IgG1A (anti-EBVCS) or anti-H-2K<sup>k</sup> and 2.0  $\mu$ I of affinitypurified goat anti-mouse immunoglobulin (6.0 mg ml<sup>-1</sup>) were used for each precipitation before addition of formalin-fixed Staphylococcus aureus. Immunoprecipitated proteins were electrophoresed in an SDS-polyacrylamide gel and visualized using autoradiography as described elsewhere . The molecular weight markers were identified by staining the gel with Coumassie blue before preparing it for autoradiography. The markers consist of *Escherichia coli* RNA polymerase (150 K, 90 K), bovine serum albumin (66 K), ovalbumin (44 K) and chymotrypsinogen (25 K).

likely to be the molecule which carries EBVCS determinants, its certain identity awaits further experimentation.

Four monoclonal antibodies bind to the same spectrum of cells and identify EBVCS determinants unique to EBV-transformed cells. The use of these monoclonal antibodies to assay these determinants quantitatively indicates that EBVCS determinants are expressed at reduced levels on cell lines established from Burkitt's lymphoma patients relative to their expression on all other EBV-transformed cell lines tested. The EBVCS determinants are among possible determinants recognized by autochthonous, cytotoxic T cells specific for EBVtransformed cells and may therefore be equivalent to LYDMA. The possibility of this equivalence is supported by the finding that EBVCS and LYDMA are expressed with the same time course in lymphocytes infected with EBV in vitro (Fig. 1 and ref. 9). If the EBVCS determinants are used by cytotoxic T cells to identify their targets, the reduced expression of EBVCS on Burkitt's lymphoma cell lines is consistent with these tumour cells having been selected in vivo to survive that cytotoxic response.

#### **Specificity of T-cell clones** illustrates altered self hypothesis

#### Thomas Hünig\* & Michael J. Bevan

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Cytotoxic T lymphocytes (CTLs) recognize foreign antigens in the context of self major histocompatibility antigens. In the mouse this phenomenon is called H-2 restriction as H-2 is the major histocompatibility complex. Two theories have been proposed to explain the dual requirement for CTLs to kill specifically target cells: (1) the two-receptor hypothesis proposes that T cells have an anti-self H-2 receptor and a distinct anti-foreign (anti-X) receptor<sup>1,2</sup>; (2) the altered self hypothesis proposes that T cells recognize complex antigens or interaction antigens created by the physical interaction of self H-2 molecules and X in the target cell membrane<sup>3,4</sup>. Here we report the isolation of CTL clones which recognize H-2k-plus-X and crossreact with H-2<sup>d</sup>-plus-Y. Because the clones recognize two pairs of antigens and not any combination, for example, H-2k-plus-Y, they support very strongly the principle of altered self recognition, that is, that only the complex of H-2 and foreign antigen is recognized and not either component independently.

<sup>\*</sup> Present address: Institut für Virologie und Immunobiologie der Universität Wurzbürg, Versbacher Strasse 7, D-8700, Würzburg, FRG.

In one set of experiments we have isolated a number of cloned, diploid, H-2k/H-2d CTL lines which were originally selected in vitro to recognize H-2k-plus-minor antigen 1 but which also recognize H-2<sup>d</sup>-plus-minor antigen 2. Radiation chimaeras (F<sub>1</sub> + parent) were constructed by reconstituting lethally irradiated B10.D2 (H-2<sup>d</sup>) mice with (B10.BR× B10.D2) $F_1$  H-2<sup>k</sup>/H-2<sup>d</sup> bone marrow cells. When immunized in vivo and in vitro with minor H antigen-different H-2k/H-2d  $(BALB.K \times BALB/c)F_1$  cells, these chimaera cells show a 10-to >50-fold preference for reacting to H-2<sup>d</sup> (that is, BALB/c) target cells. Therefore, as has been shown previously<sup>5-7</sup>, these chimaeras have a self or thymic preference in H-2 restriction. The H-2k-restricted CTLs from one chimaera which had a 20-fold H-2<sup>d</sup>-restriction preference were selected by stimulation in mixed lymphocyte culture (MLC) with irradiated BALB.K cells on days 0 and 9 of culture. On day 14 these cultures reacted well with BALB.K targets but significantly also

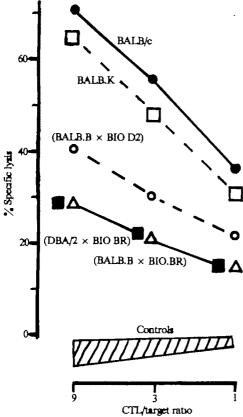

Fig. 1 Cytotoxic activity of CTL clone cr-15 on various labelled target cells. A radiation chimaera, (B10.BR×B10.D2)→B10.D2, was primed in vivo 8 weeks following the irradiation by an injection of  $(BALB.K \times BALB/c)F_1$  spleen cells. After 8 weeks, spleen and lymph node cells from the chimaera were placed in MLC with irradiated BALB.K spleen cells as stimulators in MLC medium Cells were stimulated once more with BALB.K stimulators and twice with BALB/c stimulators and were cloned on day 40 of culture according to the technique of Glasebrook and Fitch<sup>16</sup>. Long-term MLC cells were suspended at 3 cells ml<sup>-1</sup> with irradiated BALB/c spleen cells (3×10<sup>6</sup> cells ml<sup>-1</sup>) in MLC medium containing 40% conditioned medium from concanavalin Aactivated mouse spleen cells plus 50 mM a-methylmannoside. Aliquots (0.1 ml) were cultured in the wells of Coster 3596 plates. Cytotoxic ciones were maintained by weekly subculture in conditioned medium plus irradiated stimulator cells. Five months after the initial cloning, cr-15 CTLs were assayed for lysis of 51 Crlabelled spleen cell targets which had been cultured for 3 days with lipopolysaccharide. Targets were: BALB/c (●), BALB.K (□),  $(BALB.B \times B10.D2)F_1$ (O), (BALB.B×B10.BR)F<sub>1</sub> (DBA/2×B10.BR)F<sub>1</sub> (Δ). Control targets which were not sensitive to lysis included B10.D2, B10.BR, BALB.B, DBA/2 and  $(DBA/2 \times B10.D2)F_1$ . Six independent cr clones isolated at the same time as cr-15 were also able to kill both BALB/c and BALB.K targets. Furthermore, all four subclones of cr-15 had the same specificity.

reacted strongly to BALB/c targets. The cultured cells were subsequently stimulated in MLC with irradiated BALB/c stimulator cells on days 19 and 31 and were eventually cloned in limiting dilution (see Fig. 1 legend). Seven CTL clones (and subsequently a number of subclones) all with the same cytotoxic specificity were isolated. (The derivation of these clones will be described in detail elsewhere.) Figure 1 shows that the (B10.BR×B10.D2)F<sub>1</sub> CTL clone, cr-15, lyses BALB/c (H-2<sup>a</sup>) and BALB.K (H-2k) target cells very efficiently, but does not lyse either syngeneic (B10.BR×B10.D2)F<sub>1</sub> target cells nor target cells from either parent. That the CTL activity measured on BALB targets is actually true H-2-restricted anti-BALB minor activity is shown by the following cases of 'F1-specific lysis'. BALB.B (H-2b), B10.BR and B10.D2 targets are not lysed, but target cells from (BALB.B×B10.BR)F1 and (BALB.B×B10.D2)F<sub>1</sub> mice are sensitive to lysis. In these F<sub>1</sub> targets, the BALB.B parent provides a minor H antigen and the B10.BR or B10.D2 parent provides the correct restricting H-2 allele.

The most important question regarding the specificity of these CTL clones is whether the  $H-2^k$ -restricted and  $H-2^d$ -restricted minor H antigens recognized are the same or different. Clearly both antigens are present in the BALB non-H-2 background, but the B10 and BALB strains differ by >40 minor H alleles<sup>2,9</sup>. We have been able to separate the antigens genetically to show that in fact the  $H-2^k$ - and  $H-2^d$ -restricted antigens are different: cells from the DBA/2 ( $H-2^d$ ) strain and (DBA/2×B10.D2)F<sub>1</sub> mice are not sensitive to lysis by these CTL clones, whereas (DBA/2×B10.BR)F<sub>1</sub> target cells are lysed . Thus, we conclude that the  $H-2^d$ -restricted minor H antigen is present in BALB but not in DBA, whereas the  $H-2^k$ -restricted antigen is present in both BALB and DBA mice.

Further tests with these clones (Table 1) suggest that the  $H-2^k$  restriction maps to  $K^k$  as C3H ( $K^kD^k$ ) targets are sensitive to lysis whereas C3H.OH( $K^dD^k$ ) targets are not. The  $H-2^d$  restriction of the cr CTL clones probably maps to  $D^d$  as BALB/c ( $K^dD^d$ ) targets are sensitive to lysis while BALB.B ( $K^bD^b$ ) and BALB.HTG ( $K^dD^b$ ) targets are not. We conclude that these CTL clones recognize minor antigen 1-plus- $K^k$  and minor antigen 2-plus- $D^d$ .

The binding specificity of CTLs can also be studied in cold target competition assays in which the release of <sup>51</sup>Cr from one target is studied in the presence of an excess of unlabelled competitor cells. For CTL clone cr-15, the rate of lysis of <sup>51</sup>Cr-labelled BALB/c or BALB.K targets is inhibited by either BALB/c or BALB.K competitors (Table 2). This result reaffirms the clonality of the CTLs and suggests that the two targets cells interact with the same receptor. Unlabelled DBA/2 and BALB.B targets do not inhibit the CTLs. We consistently found that cold BALB/c cells are more efficient competitors than cold BALB.K even when BALB.K is the labelled indicator cell. With <sup>51</sup>Cr-labelled BALB/c as the indicator cell, BALB.K cells are 5–10-fold less efficient inhibitors than BALB/c cells. Thus, the CTLs seem to have a higher affinity for the H-2<sup>d</sup> target.

Table 1 Cytotoxic specificity of cr-15 CTLs

LPS blast target	K H	I-2 allel	es D		fic lysis at et ratio of: 2.3:1

Cloned cr-15 CTLs were assayed for lysis of <sup>51</sup>Cr-labelled lipopoly-saccharide (LPS)-induced spleen cells derived from various strains of mice

Table 2 Cold target inhibition studies of the cr-15 cloned CTL line

Unlabelled cells	% Specific 51Cr release from:			
added	BALB/c	BALB.K		
None	35	26		
BALB.B	35	28		
DBA/2	37	26		
$(B10.BR \times B10.D2)F_1$	36	27		
BALB/c	2	-2		
BALB.K	16	0		

<sup>51</sup>Cr-labelled target cells (4×10<sup>4</sup>) of BALB/c or BALB.K origin were mixed with  $2.7\times10^4$  cloned cr-15 CTLs in 1 ml of assay medium in the presence or absence of  $1.8\times10^6$  unlabelled cells from the various strains shown. The cytotoxic assay was incubated for 3.5 h. Labelled and unlabelled target cells were spleen cells cultured for 3 days with a mitogenic dose of lipopolysaccharide.

We have isolated other CTL lines having a similar crossreactive specificity. For example, an in vitro line of (C3H× DBA/2)F<sub>1</sub> (H-2<sup>k</sup>/H-2<sup>d</sup>) CTLs from normal mice binds to and lyses target cells expressing B10 minor antigen-plus-H-2<sup>d</sup> (that is, B10.D2 cells) and trinitrophenyl-bovine serum albumin (TNP-BSA)-coupled C3H (H-2<sup>k</sup>) cells<sup>10,11</sup> but does not recognize either B10 minor-plus-H-2<sup>k</sup> or TNP-BSA-plus-H-2<sup>d</sup> (ref. 12).

The fact that CTLs recognize X-plus-K and Y-plus-D but not the other combinations (X-plus-D, Y-plus-K, X-plus-Y or K-plus-D) shows that H-2-restricted T cells do not recognize foreign antigen and self H-2 as separate entities. The crossreactivity pattern cannot be explained by cross-reactivity at either the anti-self or anti-X sites which have been postulated to exist in two receptor models. The T cells are specific for the complex antigen<sup>13</sup>. Our results agree with those of Kappler et who fused two H-2-restricted cells but did not detect reshuffling of the anti-self and anti-foreign antigen specificities. It seems highly likely that the principle of the altered self hypothesis is correct, that is, self H-2 antigens modify the antigenicity of foreign antigens<sup>3,13</sup>. In this way, CTLs will recognize antigen only when it is associated with the plasma membrane of target or stimulator cells. The probable function of H-2 restriction is to focus the attention of T cells on to membrane-bound antigens.

#### Multiple conductance states of single acetylcholine receptor channels in embryonic muscle cells

#### O. P. Hamill & B. Sakmann

Max-Planck-Institut für biophysikalische Chemie. Postfach 968, D-3400 Göttingen, FRG

Acetylcholine (ACh) activates in the synaptic membrane of skeletal muscle an inward current composed of many elementary currents<sup>1,2</sup>. High resolution current measurements in adult frog muscle have shown that the elementary current is a pulselike event of unit amplitude, indicating that ACh opens ion channels which have only two conductance states, fully open or closed3. We now present evidence for a third conductance state. In the membrane of uninnervated embryonic rat muscle we observe that ACh activates two independent classes of currents of different amplitude and average duration, apparently arising from two populations of ACh receptor (AChR) channels. The currents from both classes show, at low incidence, transitions between a main level and a sublevel of lower amplitude. From this we conclude that AChR channels in embryonic muscle adopt, in addition to a 'main' conductance state, a 'substate' of lower conductance.

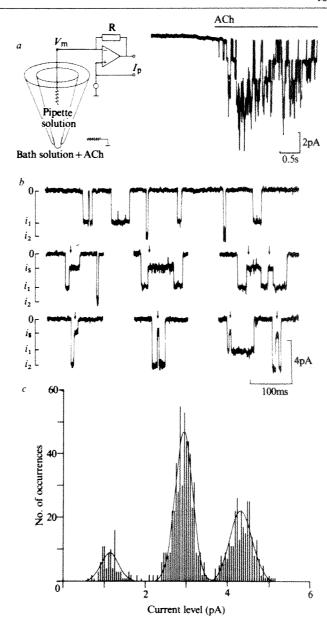

Single channel currents activated by ACh were recorded from cell-free membrane patches isolated from spherical 'myoballs'. Most experiments were performed at low temperatures (5-8 °C) using the 'outside-out' patch configuration4, in which the extracellular membrane face is exposed to the bath solution (Fig. 1a). Following addition of ACh to the bath solution at 1-2  $\mu$ M the membrane current increases from the resting level in a stepwise fashion by superposition of elementary current contributions (Fig. 1a). Figure 1b shows the waveforms of individual current contributions recorded from one patch at -100 mV. They occur predominantly as rectangular pulses of current of two different amplitudes (Fig. 1b, upper record). The mean amplitudes of these 'main' current levels are 4.3 pA and 2.9 pA, respectively (Fig. 1c). A small percentage ( $\leq 10\%$ ) of currents, however, has a more complex waveform, representative examples of which are shown in the middle and lower records of Fig. 1b. The membrane current jumps from either of the two main levels to a smaller 'sublevel' of 1.1 pA average size.

The amplitude and duration of the sublevel were measured from that class of currents where the main level was of the lower amplitude, because in all patches examined this is the more frequently occurring event. In the patch described above where the larger currents made up nearly 40% of all recorded currents, comparison of the sublevel amplitudes of the two classes (Fig. 1b, lower trace) showed that they were not significantly different, both having averages of 1.1 pA. This indicates that the size of the sublevel does not depend on the preceding main level. When the complex current waveforms described above were examined at higher time resolution (4 kHz bandwidth) no transition of the current to the baseline was seen between the two levels. At this time resolution the coincidental occurrence of two individual currents within 0.5 ms would have been detected as separate events. Following the initial transition from the main level to the sublevel the current jumps either back to the resting level or switches between the sublevel and the main level (Fig. 1b, middle traces). The frequency of occurrence of these latter complex waveforms where the current fluctuates repeatedly between the main and the sublevel, is three orders of magnitude larger than expected by unresolved coincidence of independently occurring events. These observations are consistent with the view that the complex current waveforms represent transitions of AChR channels between a main conductance state and a substate of lower conductance.

Current-voltage relationships measured in one patch in the potential range between -50 and -120 mV (Fig. 2a) indicate that the extrapolated reversal potential for the three current levels is close to 0 mV (Fig. 2b). The substate, in this case, has a conductance of 10 pS; the conductances of the two main states are 25 pS and 35 pS, respectively.

The cation selectivity of the substate seems to be similar to that of the two main states. When Na+ in the bath solution was

Fig. 1 AChR channel currents in myoball sarcolemma. The methods used in preparing myoballs and techniques of high resolution recording and patch isolation are described in detail elsewhere 4. a. The figure on the left shows schematically the current-recording configuration used to study isolated membrane patches. Outside-out patches were formed according to the following procedure. A high pipette-membrane seal (giga-seal) obtained on the muscle cell, the initial membrane patch was disrupted by suction and the pipette then slowly withdrawn from the cell. This resulted in the formation of a new membrane patch spanning the pipette tip with its the formation of a new memorane pater spanning the pipette the with its extracellular side facing the bath solution (in mM: 150 NaCl, 1 MgCl<sub>2</sub>, 1 CaCl<sub>2</sub>, 3 KCl and 10 HEPES, pH 7.2) and its cytoplasmic side facing the pipette solution (in mM: 150 KCl, 3 NaCl, 1 MgCl<sub>2</sub>, 1 EGTA and 10 HEPES, pH 7.2). The membrane potential  $V_m$  is defined as the potential of the pipette solution with respect to the bath solution. The patch current  $I_p$  is shown as a downward deflection when it flows from the bath solution into the pipette solution. Outside-out membrane patches were preferred for this study because they were typically more stable than cell-attached membrane patches, allowed ACh concentration to be adjusted during the measurements and permitted channel kinetics to be slowed by cooling to low temperatures without altering transmembrane ion gradients. The figure on the right shows the rapid activation of AChR channel currents in an outside-out patch following application (indicated by the bar) of 2  $\mu$ M ACh to the bath solution, at a potential of -70 mV, 8 °C; 400 Hz filtering. b, Oscilloscope traces showing AChR channel currents recorded at low frequency from an isolated patch of sarcolemma. The top trace is a continuous record and indicates the typical current behaviour. Two distinct classes of elementary currents  $(i_1, i_2)$  are evident. A small proportion of currents from both classes display more complex waveforms and examples are shown in the middle and lower traces. Some currents jump down to a sublevel  $(i_*)$  of ~1 pA and then either return to the resting level or jump back to the original main level. A smaller proportion of events show repetitive fluctuations between the two levels (last example in middle trace). In none of the 809 events recorded in this experiment did the sublevel precede the initial jump to the main level. In two cases the sublevel appeared in apparent isolation. Membrane potential -100 mV, temperature 8 °C. Day 14 myoball, 4 days after colchicine treatment; 1,000 Hz filtering. c, Histogram showing the relative occurrence of the three different current levels for the patch described in b. The curves are gaussian fits to the amplitudes which had mean values of 1.1, 2.9 and 4.3 pA. A total of 809 discrete current steps were recorded; 509 were in the class that had an average amplitude of 2.9 pA and 298 events were of the 4.3 pA class. Of these, 73 and 17 events, respectively, displayed the sublevel of average amplitude 1.1 pA. Three events with an average amplitude of 2.9 pA displayed a sublevel of ~2 pA, but because of the low frequency of occurrence of this level it has not been studied.

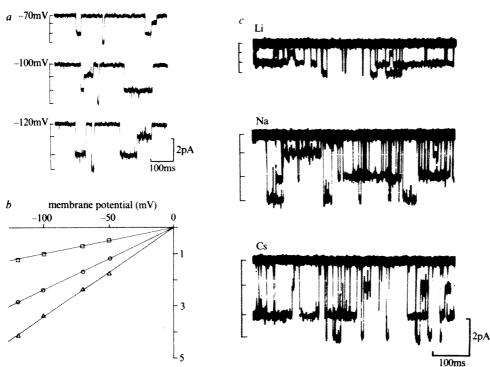

Fig. 2 Voltage dependence and ion selectivity of the three main conductance states of AChR channels. a, Current traces recorded from the same patch of myoball sarcolemma different membrane potentials. ACh concentration 1 μM, temperature 6.5 °C. Day 13 myoball, 3 days after colchicine treatment; 1.000 filtering. b, Current-voltage relationship for the three current levels measured from the patch described in a. Each data point represents the average amplitude of the level determined from 200-500 events. The lines fitted to the data points extrapolated to give reversal potential of 0 mV and yielded conductances of 10, 25 and 35 pS, c. Superimposed current traces recorded from another patch in which recordings were made in a bath solution that contained initially sodium as the pre-(150 mM), dominant cation caesium and finally lithium. Membrane potential was -100 mV. Temperature 5 °C. Day 11 myoball, 1 day after colchicine treatment; 1,000 Hz filtering. Current-voltage relationships measured in each solution over the voltage range -50 to -120 mV gave conductance values for the three levels of 4, 9 and 14 pS in Li, 8, 19 and 31 pS in Na and 11, 25 and 34 pS in Cs.

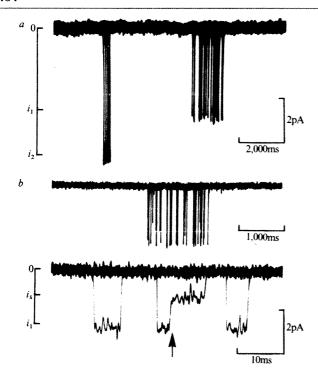

Fig. 3 AChR channel currents activated by desensitizing concentrations of ACh. a, Current recording from a sarcolemma patch activated by 10 μM ACh. Two distinct non-interacting bursts of currents were evident that corresponded in their amplitudes to the two main classes evident at low ACh concentrations. Membrane potential was -130 mV, temperature 18 °C. Day 12 myoball, 2 days after colchicine treatment; 400 Hz filtering. b, Current recording from another patch. In the top trace a burst of currents corresponding in amplitude to the smaller main level is shown at low time resolution. The bottom trace gives two superimposed traces of the same burst shown at higher time resolution. One distinct transition between the main level and a sublevel was evident and is indicated by the arrow Membrane potential -100 mV, temperature 18 °C. Day 14 myoball, 4 days after colchicine treatment; 400 and 2,000 Hz filtering.

replaced by Li<sup>+</sup> or Cs<sup>+</sup>, the conductance of all three states (Fig. 2c) decreased or increased proportionately. The various conductance states of AChR channels however differ in their average lifetime: for the patch described in Fig. 1 the average duration of the larger and smaller main levels was 12 and 36 ms, respectively, whereas the sublevel measured from the same patch had an average duration of 24 ms. However, these durations represent only apparent lifetimes because the fast fluctuations of the single channel current in the time range <1 ms (see accompanying paper<sup>5</sup>) were not taken into account. The ratio of the time the patch current is at the sublevel to the time it is at either the main or the sublevel varied between 0.02 and 0.12 in six different patches, indicating that the probability of the open channel adopting the substate is low. It is further reduced when the temperature is increased: at 18 °C current sublevels are only measurable as short notches (<5 ms) in the channel's closing time course. On the other hand, increasing the membrane potential from -70 mV to -120 mV (temperature 5 °C) increased the probability of the open channel adopting the substate from 0.05 to 0.15 (one patch). When channels have adopted the substate, the probability that they either close completely or open fully was similar. For example, in the patch illustrated in Fig. 1 the ratio of transitions back to the main state to transitions to the closed state was 1.3. Apparent transitions between the two main current levels are also observed, but their average number is not significantly different from that expected by unresolved random coincidence of two main unit current events.

These findings suggest that ACh activates two independent classes of channels in embryonic rat muscle that are distinguished by a slightly different main conductance. Both can adopt, with low probability, a similar substate of lower conductance.

This view is further supported by experiments where channels were activated by ACh at concentrations  $>2 \mu M$  where single channel currents appear in bursts. Bursts reflect sequential open-close transitions of the same AChR channel<sup>6</sup>. In embryonic muscle they fall into two main classes with respect to the size of their current pulses, corresponding to the two classes observed at low ACh concentration (Fig. 3a). Transitions between these two main current levels were never observed during a burst. However, transitions between the main level and the sublevel do occur, as shown in Fig. 3b. The upper trace shows a burst of current pulses at low time resolution, consisting of 25 well separated current events. At high time resolution two events have a complex shape characterized by a transition from the main level to the sublevel. One of these events is illustrated in the lower trace of Fig. 3b. The average probability of this channel being in the substate (given the channel is in the open state), as determined from eight consecutive bursts, was 0.08. This experiment shows directly that a single AChR channel complex, in the presence of constant ACh concentrations, fluctuates between at least three states: a main open state, a substate which is adopted at low probability, and the closed

The AChR complex purified from Torpedo electroplaque is a pentameric protein complex comprised of five homologous subunits<sup>7</sup> which span the membrane<sup>8</sup>. In lipid bilayers it can form a unit conductance channel which has a similar conductance to that of the AChR channel in rat muscle9. The observation that ACh-activated channels in embryonic muscle cells can adopt several conductance states could indicate that these subunits rearrange themselves to form the different open states of a channel. Similarly the two independent classes of channels may represent two different aggregation states of the same set of subunits.

Max Planck Institut für biophysikalische Chemie, D-3400 Göttingen, FRG

Acetylcholine-like drugs cause ion channels in the skeletal muscle endplate to open briefly1, producing, at random intervals, rectangular pulses of current with constant amplitude but random duration, that can be recorded by the patch clamp method<sup>2,3</sup>. However, even when the agonist concentration is so low that channel activations are very well separated, we have observed, with high resolution methods4, that openings may be interrupted by shut periods (gaps) so brief that they are very unlikely to arise from two independent channel activations. This sort of behaviour has been predicted on the basis that two or more openings might occur during the time for which the receptor remains occupied by agonist<sup>5,6</sup>. If this were correct, important new information about agonist activation of ion channels could be obtained from measurements of the gaps between openings. However, short gaps could arise in other ways: for example from brief blockage of the ion channel<sup>7</sup>, perhaps by the agonist itself. We now present results obtained with the acetylcholine-like agonist, suberyldicholine (SubCh, 20–100 nM), which suggest that the brief gaps do not result from ion channel block by the agonist itself, but which are consistent with a mechanism in which the channel opens and closes several times during a single agonist receptor occupancy. We have also observed that the number of short (<1 ms) current pulses is greater than we expected.

Single ion channel currents from the perisynaptic region of normal frog (*Rana temporaria*) cutaneus pectoris muscle were recorded at 10–13 °C (ref. 4). The Ringer solution contained (mM) NaCl 115, KCl 2.5, CaCl<sub>2</sub> 1.8 and HEPES buffer 3, pH 7.2

Figure 1a shows the typically low frequency of single channel currents (always  $<3\,\mathrm{s}^{-1}$ ). Individual currents are shown, with high time resolution, in Fig. 1b,c; they are clearly interrupted by brief gaps. During most of these gaps the current does not reach the resting value; however, the frequency response of the system is such that the channel would have to be shut for nearly  $300\,\mu\mathrm{s}$  for this to be attained. We assume that the gaps represent brief, but complete, closures of the ion channel, and Fig. 1d–g show how the duration of such closures was estimated. In good records, events with a duration of 50– $70\,\mu\mathrm{s}$  could be clearly resolved.

The entire record was digitized so that the duration of all resolvable gaps, as well as openings, could be measured. After this measurement, a safe value was chosen for the minimum resolvable duration, and the record was revised by concatenation of adjacent gaps and openings separated by intervals less

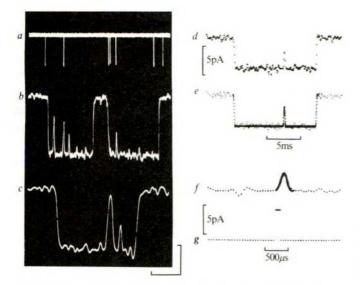

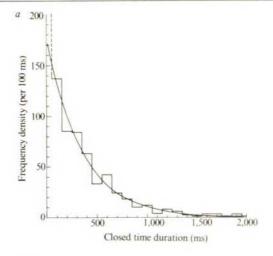

Fig. 1 Examples of single channel currents (a, b, c) and the method used to fit their time course (d, e, f). Low pass filter set at 4 kHz. a, Illustration of low frequency of events (seven in 5 s in this case) with 100 nM SubCh at -123 mV. Calibration bars: 4 pA and 1 s. b, Several brief closures interrupting an open channel current; taken from the experiment illustrated in a. Calibration bars: 2 pA and 10 ms. c, Another group of three openings, at higher time resolution than in b; 20 nM SubCh at -128 mV. Calibration bars: 2 pA and 2 ms. d, A burst with one resolvable gap, digitized at 16 kHz; 50 nM SubCh at -171 mV. e, The same data as in d with a fitted line (heavy line) superimposed on it. The response of the recording system to a step input was measured experimentally, and four such response functions, with alternating direction, were convolved to generate the fitted line. f, The gap shown in d and e, with greatly expanded time scale, but the same amplitude scale. A fitted line is superimposed on the data to illustrate the fitting of brief gaps. This fitted line was generated, as explained above, as the expected response of the system to the input shown in g. This fit estimates that the burst shown in d consists of two openings of length 7.69 and 4.58 ms, separated by a gap of 104 µs, so the total length of the burst is 12.37 ms.

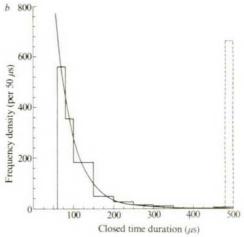

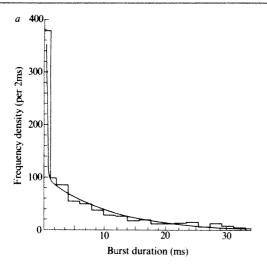

Fig. 2 Distribution of the durations of all closed times (gaps) between open channel currents. Experiment with 20 nM SubCh at -131 mV. Ordinate is frequency density (number of observations per time interval of the specified length). All 1,308 gaps that were measured were simultaneously fitted (as described in the text) with the sum of three exponentials, and the fitted curve was superimposed on the histogram of the observations which is shown with two different time scales in a and b. In this case we found components with time constants of 352 ms (representing 20.5% of total area under the distribution), 45 μs (76.7% of area) and 0.66 ms (2.8% of area). a, Distribution of gaps, shown up to 2,000 ms, with fitted curve. The leftmost bin (dashed line) contains many short gaps, and extends well off the graph. b, The same distribution, shown up to 500 μs, only, with fitted curve. The resolution was fixed (see text) at 60 μs in this experiment. The rightmost bin (dashed line) represents all gaps longer than 500 μs. This includes all those shown in a.

than this chosen resolution. Thus an idealized record, with consistent resolution throughout, was obtained for the construction of histograms. All distributions of time intervals were fitted with the sum of one or more exponential functions by the method of maximum likelihood (that is, the actual measured durations were used, not the histogram frequencies).

The distribution of all gaps is exemplified in Fig. 2. In Fig. 2a, the time scale extends up to 2 s, and the gap durations are fitted well by an exponential component with a mean of 352 ms. This is presumably the mean interval between independent activations of ion channels. However, the first bin (up to 50 ms) extends a long way off the graph; the distribution of short gaps is shown in more detail in Fig. 2b, in which the time scale extends up to only  $500 \, \mu s$ . There is a clear exponential component of the gap distribution with a mean, in this example, of  $45 \, \mu s$ , which corresponds to the short gaps illustrated in Fig. 1. Values of  $45-70 \, \mu s$  were consistently observed in nine other experiments. This fast component represented, in this case, 77 per cent of the total area of the gap duration distribution, corresponding to a total number of 2,231 short gaps (although many of these would

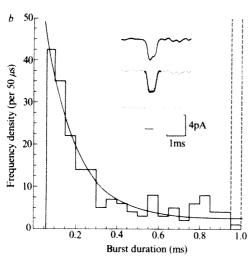

Fig. 3 Distribution of the burst duration, as defined in the text, for the same experiment as shown in Fig. 2. With a resolution of 60 µs and critical gap length of 1.5 ms, there were 683 bursts altogether. The durations of these bursts were fitted (see text) with the sum of two exponentials. In this case we found components with time constants of 10.2 ms, which is similar to the value expected from a noise analysis in the conditions of this experiment, and 0.15 ms. In 12 experiments the average faster time constant was  $0.35 \pm$ 0.12 ms. a, The distribution of burst length, and fitted curve, shown up to 35 ms. b. The same distribution and fitted curve, but bursts up to 1 ms duration only are shown. The rightmost bin (dashed line) represents all bursts longer than 1 ms. The inset shows (top) an example of a brief opening. This is fitted (see Fig. 1, right column) with a superimposed line (middle) calculated as the response to the step input shown (bottom). The amplitude (3.95 pA) was taken as the average of amplitudes of all full size openings previously fitted in this experiment. The duration is 495 µs.

be too short to resolve). In addition we have consistently found a much smaller component (about 2% of total area) with an intermediate time constant of the order of 1 ms, but this will not be considered further here.

The evidence presented above suggests that the 'openings' will contain many unresolved gaps, and are thus not well defined. We therefore define a burst of openings as any series of 'openings' interrupted by gaps that are all less than some critical length (usually 0.5-3 ms). Insofar as this length is very much smaller than the mean time between independent events (352 ms in Fig. 2), the burst duration is a well defined quantity. This occurrence of openings in quick succession was called the Nachschlag phenomenon when it was first observed, and this term seems appropriate, whatever the mechanism responsible for the phenomenon. Figure 3 shows the distribution of burst durations; in Fig. 3a the time scale extends to 35 ms, and there are obviously too many short bursts to be fitted by a single exponential distribution. The double exponential distribution shown has a slow component with mean of 10.2 ms, and a fast component with mean of 0.15 ms. The total area under the distribution represents 717 bursts and the slower component corresponds to 73% of the total area in this example, with 20 nM SubCh. Thus we infer, for the experiment illustrated in Figs 2 and 3, that there are, on average 2,231/717 = 3.1 gaps per burst. Similar values (2-4) were found in 10 experiments.

The origin of the short openings illustrated in Fig. 3 is obscure. They may represent a separate type of channel altogether, or perhaps brief openings by channels with only one agonist molecule bound. We shall explore these hypotheses elsewhere.

The most important question that arises is whether the brief gaps result from ion channel block by the agonist, SubCh, itself. Decamethonium (in much higher concentrations) is known to do this<sup>8</sup>. If this were the mechanism, the number of gaps (blockages in this case) per burst should be directly proportional to the agonist concentration. However, the number of gaps per burst with 100 nM SubCh, relative to that with 20 nM, was  $0.97 \pm 0.11$ (three experiments at each concentration), and showed little sensitivity to membrane potential. Therefore, ion channel block by SubCh, in the low concentrations used, cannot explain the brief gaps that we observe. Although it is conceivable that brief closures of the channel might arise from block by some endogenous muscle constituent, or from a mechanism connected with ion permeation, the most plausible alternative to ion channel block is that the closures arise from multiple openings during a single receptor occupancy<sup>5,6</sup>. Suppose, for example, that two agonist molecules must bind sequentially before the channel can open (see, for example, ref. 9). Then (see ref. 6), at low agonist concentration, the mean length of a gap should be approximately  $(\beta + 2k_{-2})^{-1}$ , and the number of gaps per burst should be approximately  $\beta/2k_{-2}$ , where  $\beta$  is the rate constant for opening of a doubly occupied receptor-channel complex, and  $k_{-2}$  is the microscopic rate constant for dissociation of an agonist molecule. Our results, if interpreted in this way, thus suggest preliminary estimates for  $\beta$  of the order of  $10,000-15,000 \text{ s}^{-1}$ , with  $k_{-2}$  roughly  $2,000 \text{ s}^{-1}$ . This interpretation of our results with SubCh is not compatible with the common assumption that the agonist binding step is very fast, and that the open-shut conformation change is rate-limiting<sup>10</sup>. We are now investigating whether or not the same can be said of agonists other than SubCh. The noise spectrum expected if this interpretation were correct would consist predominantly of a single component, with a time constant close to the mean length of the burst (slow component), that is, 10 ms in the experiment shown in Fig. 3. But this time constant would not correspond, as is often assumed, to the true lifetime of the open state. In the above example the average burst consists of roughly four openings in quick succession, so the mean open lifetime,  $1/\alpha$  (where  $\alpha$  is the channel closing rate constant) would be only about 2.5 ms.

Results similar, in some respects, to ours have recently been found (S. G. Cull-Candy and I. Parker, in preparation) for glutamate-operated channels in locust muscle.

#### A specific substance P antagonist blocks smooth muscle contractions induced by non-cholinergic, non-adrenergic nerve stimulation

# S. Leander\*, R. Håkanson\*, S. Rosell†, K. Folkers‡, F. Sundler§ & K. Tornqvist||

Nerve fibres containing substance P (SP) are widely distributed in the body1-3 and seem to innervate autonomic ganglia, blood vessels, epithelial structures and smooth muscle. SP stimulates secretion from exocrine glands, causes vasodilation and contracts non-vascular smooth muscle4. The presence of SP in primary sensory neurones has lent support to the view that it is associated with sensory nerve conduction, conceivably as a transmitter5, and that it is a causative factor in the 'irritative' response to antidromic stimulation of sensory nerves°. Gut smooth muscle contracts in response to non-cholinergic, non-adrenergic nervous stimulation<sup>7,8</sup>, and it has been suggested that SP acts as an excitatory transmitter in intramural neurones in the gut wall<sup>2,3,9,10</sup>. Recently, a series of synthetic analogues of SP with antagonist activity to SP has been developed 11,12. We report here that a new analogue, (D-Pro2, D-Trp7.9)-SP, exercises a specific, possibly competitive antagonism to SP. While being a partial agonist it antagonized the contractile response to applied SP and to non-cholinergic, non-adrenergic nerve stimulation in the isolated guinea pig taenia coli and rabbit iris sphincter pupillae muscle, suggesting that SP, or a closely related peptide, is indeed a motor excitatory transmitter. In contrast, (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP did not inhibit the contractile response to non-cholinergic, non-adrenergic nerve stimulation of smooth muscle from the guinea pig urinary bladder.

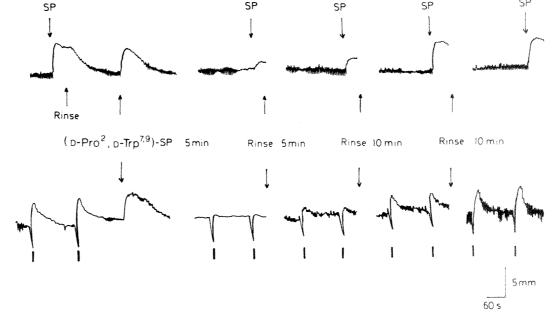

Guinea pig taenia coli preparations, consisting of longitudinal smooth muscle with the attached myenteric plexus<sup>13</sup>, were

placed in Krebs solution, stored at 4°C for ~1 h and then mounted vertically on a Perspex holder in a 7-ml organ bath thermostated at 37 °C. One end was attached to a rigid support and the other to a lever connected via a spring to a Grass FT03 force displacement transducer or to a photoelectric transducer for isotonic registration of mechanical activity. The load on the muscle was set at 0.2 g. Platinum ring electrodes were placed around the muscle with a constant electrode distance of 5 mm and the electrodes were connected to a Grass S 4C stimulator for field stimulation with square wave pulses (15 V over the electrodes, 0.5-1 ms duration). The muscles were stimulated with trains of pulses lasting 3 s and with a frequency of 1-5 Hz, the resting period between stimulations being at least 2 min. The mechanical activity of the preparation was continuously recorded on a Grass model 7 or model 5 polygraph. The bathing fluid was a modified Krebs solution of the following composition (in mM): NaCl 133, NaHCO $_3$  16.3, KCl 4.7, MgCl $_2$  1.0 NaH $_2$ PO $_4$  1.4, CaCl $_2$  2.5 and glucose 7.8. The solution was bubbled with a gas mixture of 7% CO2 in O2 giving a pH of 7.2 - 7.3.

The sphincter pupillae muscle of the rabbit iris was excised, opened and mounted as described for the taenia. Mucosa-free strips of the detrusor of the guinea pig bladder were prepared as described in detail elsewhere 14. The same procedure as above was used to study the motor activity of the sphincter pupillae and the urinary bladder except that they were placed directly in the bath, experiments with sphincter pupillae muscle were run at 35 °C, and the stimulation parameters were 10–20 Hz for 10 s for the sphincter pupillae muscle 15 and a single pulse every 20 s for the urinary bladder. (D-Pro², D-Trp².9)-SP was synthesized by techniques analogous to those described elsewhere 11.

The addition of SP and of (D-Pro<sup>2</sup>, D-Trp<sup>7.9</sup>)-SP to guinea pig taenia coli produced a contraction which lasted  $120-150 \,\mathrm{s}$ , the tension subsequently returning to baseline (Fig. 1). As illustrated in Fig. 2a the contractile effect of the SP analogue required high concentrations. The contractile response to exogenous SP was strongly inhibited by pretreatment with (D-Pro<sup>2</sup>, D-Trp<sup>7.9</sup>)-SP (Fig. 1), the blockade lasting for at least 30 min without washing. Washing out the SP analogue resulted in a return of the contractile response to exogenous SP and to electrical stimulation (Fig. 1). The analogue also reduced the contractile response to exogenously applied physalaemin and eledoisin but not that to carbachol, histamine, serotonin, bradykinin, Lys<sup>8</sup>-vasopressin or prostaglandin  $F_{2\alpha}$  (Fig. 3). In the presence of (D-Pro<sup>2</sup>, D-Trp<sup>7.9</sup>)-SP, the dose response curve

**Fig. 1** Effect of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP  $(10^{-5} \text{ M})$  on the contractile response to exogenous substance P (SP; Peninsula) (5×10<sup>-9</sup> M) Peninsula) (upper panel) and to the electrically evoked contraction (lower panel) of isolated guinea pig taenia coli. The stimulated in the presence of atropine ( $10^{-6}$  M; ACO) and guanethidine ( $5 \times 10^{-6}$  M; Sigma) for 3s with 3 Hz as indicated by black rectangles. Note the agonist effect of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP, the ensuing blockade of the contractile response to exogenous SP and the reduction of the electrically induced contraction on addition of the SP analogue. Electrical stimulation applied 5 min after contractile effect of (D-Pro2, D-Trp7.9)-SP had subsided.

The inhibitory effect of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP on smooth muscle contractions can be washed out as illustrated by the recovery of the contractile response of the taenia coli to exogenous SP and to electrical nerve stimulation. Rinsings and time intervals between registrations are indicated. The registrations shown are typical examples of four to six experiments,

0028-0836/81/490467---03\$01.00

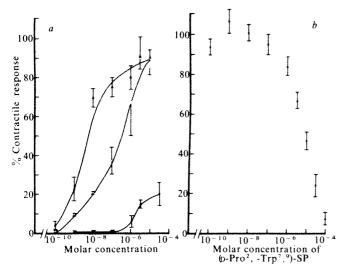

Fig. 2 a, Dose-response curves showing the effects of SP alone ( $\triangle$ ), of SP in the presence of (D-Pro2, D-Trp7.9)-SP (O), and of (D-Pro2, D-Trp7.9)-SP alone (●) on the tension of the guinea pig taenia coli, expressed as percentage of the contraction induced by carbachol (10<sup>-5</sup>; Merck-Darmstadt). In the presence of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP (10<sup>-5</sup> M) the dose-response curve for was shifted 2.54 log units to the right, suggesting competitive inhibition. The dose-response curves were constructed by adding step wise increasing amounts of peptides to the bath. Below  $10^{-7}$  M three concentrations of SP were tested on each muscle; above  $10^{-7}$  M only one concentration was tested per muscle. The corresponding concentration for the SP analogue was 10<sup>-6</sup> M. SP was added in a volume of 200 μl, the SP analogue in 40 μl. Between each addition the bath was rinsed until the tension had returned to base line (usually three rinses, in all 5-10 min). Each value is the mean of 3-10 experiments. Vertical bars give s.e.m. b, Effect of increasing concentrations of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP on the contractile response of the isolated guinea pig taenia coli to electrical stimulation (3–5 Hz, 3 s). Atropine  $(10^{-6} \, \mathrm{M})$  and guanethidine  $(5 \times 10^{-6} \, \mathrm{M})$  were present in the bath. New muscles were set up for each concentration tested. Electrical stimulation was applied 5 min after the contractile response to the SP analogue had subsided. The results are expressed as per cent of the contractile responses before adding the SP analogue. Each value is the mean of 4-18 experiments. Vertical bars give s.e.m.

for SP was shifted to the right in a manner suggesting competitive inhibition (Fig. 2a). Desensitization with SP is a well known phenomenon, but it can be ruled out as an explanation for the inhibitory effect of the SP analogue because high concentrations of SP ( $>10^{-6}$  M) could overcome the inhibition, very high concentrations ( $>10^{-8}$  M) giving a maximal contractile response.

Électrical stimulation (1-5 Hz, 3 s) of the taenia elicited a strong contraction, and this response was not affected by addition of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP. Following addition of the muscarinic blocker atropine (10<sup>-6</sup> M) and the anti-adrenergic drug guanethidine (5 × 10<sup>-6</sup> M), the taenia responded to low-frequency stimulation (1 Hz, 3 s) by relaxing. With higher-frequency stimulation (3-5 Hz, 3 s), the initial relaxation was followed by a contraction on cessation of stimulation<sup>10</sup>. Both these responses were inhibited by tetrodotoxin, indicating a neuronal mediation<sup>16</sup>. Although relaxation was unaffected, the amplitude of the contraction was greatly reduced by pretreatment with (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP (Fig. 1). Interestingly, the dose-response curve revealed that a 10<sup>-4</sup> M concentration of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP reduced the contraction by more than 90% (Fig. 2b).

The iris sphincter pupillae muscle responded to both SP and electrical stimulation with a slow contraction, in the latter case reaching a maximum 30-40 s after cessation of stimulation. The electrically induced contraction lasted for  $\sim 150$  s. Cholinergic and adrenergic blockade had very little effect on the response to electrical stimulation, but (D-Pro², D-Trp², )-SP caused a dramatic reduction in the contractile response (Fig. 4a). The remaining contraction was further reduced by adding tetrodo-

toxin. As in the taenia coli, the response of the iris sphincter muscle to exogenous SP, physalaemin and eledoisin (but not that to carbachol) was greatly inhibited by pretreatment with (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP.

The guinea pig urinary bladder responded to both SP and electrical stimulation with a contraction. Cholinergic and adrenergic blockade had little or no effect on the response to electrical stimulation<sup>14</sup>. Also, (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP failed to inhibit the response, which could be completely abolished by tetrodotoxin (Fig. 4b).

The results of these experiments indicate that (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP is a partial agonist, exercising a specific, possibly competitive antagonism to SP. Interestingly, (D-Pro<sup>2</sup>, D-Trp<sup>7</sup>, also blocked the effects of physalaemin and eledoisin. Together these peptides have been grouped under the name tachykinins<sup>17,18</sup>; they have the carboxy-terminal three amino acids in common and display smooth muscle stimulating effects<sup>17,18</sup>. Following cholinergic and adrenergic blockade, electrical nerve stimulation still induced a contraction of the guinea pig taenia coli, urinary bladder and rabbit sphincter pupillae muscle. In the taenia coli and sphincter pupillae muscle these contractions were greatly reduced by (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP, suggesting that SP is involved as a motor excitatory transmitter. However, the SP analogue did not inhibit the contractile response to electrical nerve stimulation of the urinary bladder following cholinergic and adrenergic blockade. Hence, SP is not in all tissues the only non-cholinergic, non-adrenergic motor excitatory neurotransmitter. SP nerve fibres in the smooth muscle of the taenia coli probably originate from cell bodies in the mysenteric plexus 10,19-21, but their precise nature and mode of action remain to be established. Our results suggest that they are engaged in an efferent motor excitatory capacity although it cannot be excluded that SP is released as a result of antidromic nerve stimulation. The SP fibres in the sphincter pupillae muscle

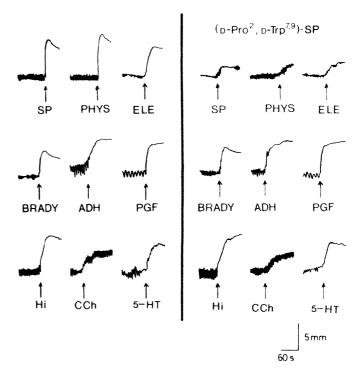

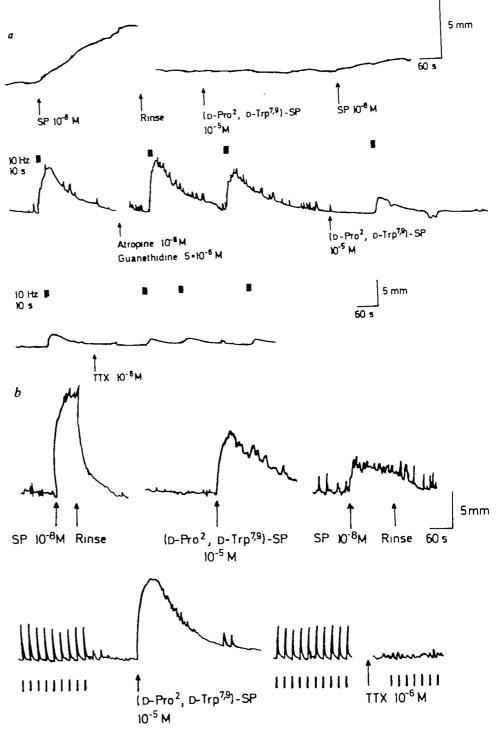

Fig. 3 Contractile response of the isolated guinea pig taenia coli to physalaemin (PHYS), eledoisin (ELE; both Peninsula) at a concentration of  $10^{-9}\,\rm M$ , SP bradykinin (BRADY; Beckman), histamine (Hi; Merck-Darmstadt), carbachol (CCh) and serotonin (5-HT; Sigma) at a concentration of  $10^{-8}\,\rm M$ , Lys\*-vasopressin (antidiuretic hormone, ADH; Ferring) and prostaglandin  $\rm F_{2\alpha}$  (PGF; Sigma) at a concentration of  $10^{-7}\,\rm M$ , with (right) or without (left)  $10^{-5}\,\rm M$  (D-Pro², D-Trp²-9)-SP in the bath. The contractile effect of the SP analogue was allowed to subside before the other compounds were added, usually 5 min later.

Fig. 4 a, Effect of (D-Pro2, D-Trp7.6)-SP on the contractile response to exogenous SP (upper panel) and to the electrically evoked contraction (middle and lower panels) of the rabbit iris sphincter pupillac muscle. In this preparation the SP analogue per se had no contractile effect. Electrically induced contraction per sisted in the presence of atropine and guanethidine. Note the absence of contractile effect of exogenous SP and the reduction of the electrically evoked contraction following addition of the SP analogue, Addition of tetrodotoxin (TTX. Sankyo) almost completely abolished the residual contractile response b, Effect of (p-Pro<sup>2</sup>, p-Trp<sup>7,9</sup>)-SP on the contractile response to exogenous SP (upper panel) and to the electrically evoked contraction (lower panel) of the gumes pig urinary bladder. The muscles were electrically simulated in the presence of atropine  $(10^{-6} \text{ M})$  and guanethidine  $(5 \times 10^{-6} \text{ M})$ with a single pulse every 20 s as indicated Note the agonist effect of (D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>)-SP, the ensuing blockade of the contractile response to exogenous SP and the lack of effect on the electrically induced contraction on addition of the SP analogue, Electrical stimulation or exogenous SP were applied 5-10 mm after the contractile effect of (D-Pro<sup>2</sup>, D-Trp<sup>2</sup>)-SP had subsided. Addition of TTX completely abolished the contractile response to the electrical field stimulation. The results shown in a and b are typical examples from a series of four to six experiments

are probably derived from the trigeminal nerve 15,22,23, which is assumed to have a sensory function. Hence, the SP-mediated contraction is either the result of antidromic nerve stimulation or an indication that the trigeminal nerve carries efferent fibres.

# Distinct subpopulations of enteric p-type neurones contain substance P and vasoactive intestinal polypeptide

#### L. Probert, J. De Mey\* & J. M. Polak

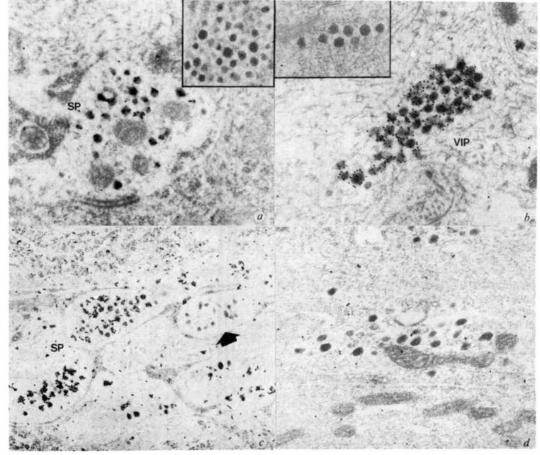

Unit of Histochemistry, Department of Histopathology, Royal Postgraduate Medical School, Hammersmith Hospital, London W12 0HS, UK and \* Laboratory of Oncology, Janssen Pharmaceutica, 2340 Beerse, Belgium

Enteric nerve profiles ultrastructurally distinct from the adrenergic and cholinergic types have been recognized for more than a decade1. Baumgarten and his colleagues2 called these neurones p-type (peptidergic) because they contain large, granular, secretory vesicles similar to those found in peptidecontaining nerves in the brain. Subsequently ultrastructural heterogeneity within this extensive non-adrenergic, non-cholinergic p-type system was described, based on the appearance of these granular vesicles3. This was consistent with the light microscopical demonstration of increasing numbers of peptides in the gut innervation<sup>4,5</sup>, and has been further supported by the localization of vasoactive intestinal polypeptide (VIP) immunoreactivity within large p-type secretory vesicles in the cat proximal colon6. Using electron-immunocytochemical techniques on aldehyde-fixed tissue we have shown that the morphological heterogeneity of the p-type system is partly due to the storage of different peptides. We present here evidence that two peptides, VIP and substance P (SP), are present in separate subpopulations of p-type neurones distinguishable by the size and appearance of their granular secretory vesicles. Further subpopulations, unlabelled by specific anti-SP and anti-VIP sera, are also present.

A colloidal gold-labelled second layer antibody was used in a two-step immunocytochemical technique based on the original method of Romano and his colleagues7. Purified goat IgG was labelled with colloidal gold particles measuring 20 nm in diameter<sup>8</sup> (see also Fig. 2 legend), in a technique modified from existing methods<sup>7,9-11</sup>. Antisera to SP and VIP were raised in . Antisera to SP and VIP were raised in rabbits and characterized for immunocytochemistry (Table 1 and Fig. 2 legend). The colon from adult guinea pigs (n = 15) was used (Fig. 1 legend). The method for immunostaining ultrathin sections was similar to that described by Roth et al. 12, Larsson 1 and Batten and Hopkins<sup>14</sup>. Briefly, ultrathin sections were etched with 10% H<sub>2</sub>O<sub>2</sub> for 15 min, incubated with normal goat serum (1/30 dilution) and then either SP or VIP antiserum for 18 h at 4 °C (Table 1). The sections were rinsed with 0.05 M Tris-buffered saline pH 7.3 (TBS) containing 0.2% bovine serum albumin (BSA)7, before incubation with gold-labelled goat anti-rabbit IgG for 1 h at room temperature (see Fig. 2 legend). Following another wash in TBS/BSA buffer the sections were counterstained with uranyl acetate and lead citrate. Controls were carried out as described in Fig. 2 legend.

Throughout the wall of the guinea pig colon, SP- and VIP-like immunoreactivities were consistently found in the large granular secretory vesicles present in separate and distinct sub-populations of p-type neurones (Fig. 1). Furthermore, these neurones could be distinguished by the size and appearance of the secretory vesicles. Immunoreactivity was observed mainly in

Fig. 1 Ultrathin sections of guinea pig myenteric plexus showing nerve terminals: a, immunostained with antiserum (SP) (resin polymerized at 60°C); ×30,000 (inset showing control section stained using SP antiserum preabsorbed with SP antigen (see Table 1); ×30,000). Immunostained with antiserum (VIP); ×30,000 (inset showing control section stained with VIP antiserum preabsorbed with VIP antigen (see Table 1); ×30,000. Immunostained with antiserum showing positive (SP) and negative terminals (resin polymerized 60°C); ×20,000. Immunostained with antiserum (also negative following application of SP antiserum); ×30,000. Note the specific gold labelling over the large, granular, p-type vesicles present in the nerve terminals shown in a and b. Control sections, as shown in the insets, were completely unstained. The colon was removed from adult Dunkin Hartley guinea pigs under pentobarbitone anaesthesia. Proximal, middle and distal regions were diced and immersion fixed in a cold solution of 3% glutaralde-hyde in 0.1 M phosphate buffer pH 7.3, for 3 h at 4°C. The tissue was washed over-

night in 0.1 M phosphate buffer pH 7.3 containing 0.1 M sucrose, dehydrated and embedded in Araldite. Resin was polymerized either at 60 °C (SP) or at 18 °C using UV light (SP and VIP). Ultrathin sections were cut on a Reichert Ultracut microtome, collected on uncoated 300-mesh nickel grids and immunostained as described in the text. In addition, alternate serial sections from blocks polymerized using UV light were stained with either SP or VIP antiserum so that a direct comparison of vesicle types could be made. A statistical comparison of the results was carried out using an unpaired Student's r-test.

nerve terminals and varicosities although VIP-immunoreactive vesicles were occasionally seen in cell bodies of the submucous plexus (Fig. 2). SP-immunoreactive neurones are also known to be present in the guinea pig gut<sup>4,15</sup> but none was identified in this study. As an extensive study of samples throughout the colon of each animal (n = 15) was undertaken, this may be explained either by the presence of a non-reactive precursor form, or a concentration too small to be detected by immunocytochemistry in the cell bodies. Optimal immunostaining of SP and VIP was obtained following different resin polymerization schedules (see Fig. 1 legend). To achieve an accurate comparison of SP- and VIP-immunoreactive vesicles, staining for both peptides was carried out in parallel on alternate serial sections from blocks polymerized at 18 °C with UV light. Section thickness and staining density were standardized as much as possible as these factors are known to affect the electron density of ultrathin sections. Interestingly, the different methods of resin polymerization produced no difference in the size of the vesicles, although they did appear to be slightly less electron dense in the blocks polymerized at the lower temperature. Both SP- and VIP-immunoreactive vesicles were predominantly spherical in shape, although occasionally ovoid or slightly elongated immunoreactive vesicles were observed in terminals of each type. Comparison of the serial sections taken from low temperature cured blocks showed the VIP-immunoreactive vesicles to be significantly larger (mean ± s.d.) (98 ± 19 nm diameter) than the SP-immunoreactive vesicles ( $85 \pm 15 \text{ nm}$ diameter) (P < 0.01, see Fig. 1 legend), and more electron dense. At least two further subclasses of p-type nerve terminals were present which remained unstained by SP or VIP antiserum. These contained (1) mainly elongated vesicles of medium electron density measuring  $74 \pm 11 \times 91 \pm 25$  nm (Fig. 1c), and (2) large (105±31 nm), spherical vesicles with a homogeneous, dense core (Fig. 1d).

We present here evidence that within the heterogeneous p-type innervation of the guinea pig gut, two of the most abundant gut neuropeptides, SP and VIP, are stored in distinct types of nerve terminals distinguishable by the size and appearance of their large, dense-cored secretory vesicles. In addition, further subclasses of p-type terminals, unstained by either SP or VIP, can be seen. The present stage of the classification of peptide-containing nerves is reminiscent of the early description of all gut endocrine cells as enterochromaffin cells16. These were subsequently subdivided ultrastructurally17, but it was not until immunocytochemical techniques were applied that a functional classification could be attempted. This led to the identification of the peptides present in 14 out of the 18 cell types 18. The original p-type terminals have reached the stage of morphological subclassification3 and two subtypes have been reclassified by immunocytochemistry. Of the nine types of nerve profiles described, three variations of p-type terminal were reported by Cook and Burnstock3 according to vesicle size and appearance. The types 5b (see their Fig. 28) and 5c (see their Fig. 29) resembled most clearly the SP- and VIP-immunoreactive vesicles, respectively, as described here. Conclusive identification is difficult because fixation conditions in the two studies were not identical. As a wide range of biologically active peptides is known to be present in the innervation of the mammalian gut4.5, it is likely that at least some of these will be localized to further kinds of p-type terminal. The availability of

Table 1 Characterization of antisera for immunocytochemistry

Absorption (1–10 nmol per Antiserum ml diluted antiserum)								
to	Reference	Titre	BN	VIP	SP	GIP	GLUC	SEC
VIP	(652)	1/6,000	+	-(5)	+	+	+	+
SP	(479)	1/8,000	+	+	-(3)	+	+	+

Reference: antiserum reference number. Controls included the application of antiserum preabsorbed with bombesin (BN), gastric inhibitory polypeptide (GIP), glucagon (Gluc), secretin (Sec), VIP and SP; +, no change in the intensity of immunostaining; -(nmol ml-1), minimum amount of peptide required to abolish the immunostaining.

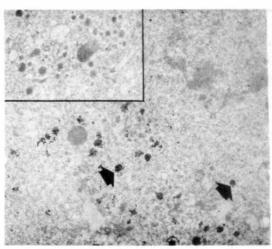

Fig. 2 Ultrathin section of guinea pig submucous plexus showing a VIPimmunoreactive neuronal cell body. Note the specific gold labelling over the large p-type vesicles present in the cytoplasm (arrows); ×20,000 (inset showing serial section stained with VIP antiserum preabsorbed with VIP antigen (see Table 1); ×20,000). SP and VIP antisera were raised in rabbits using synthetic SP (Beckman) coupled to thyroglobulin, and natural porcine VIP (donated by Professor V. Mutt, Karolinska Institute, Stockholm) coupled to haemocyanin with glutaraldehyde, respectively. Both antisera were characterized for immunocytochemistry and found to be directed to the C-terminal portions of their respective molecules. Controls for immunocytochemistry included incubation with the following in place of the first layer antiserum: (1) SP or VIP antiserum preabsorbed with synthetic SP or VIP antigen respectively (1-10 nmol ml<sup>-1</sup> diluted antiserum, see Table 1); (2) non-immune serum; (3) gold-labelled antibody alone; (4) SP or VIP antiserum preabsorbed with other gut peptides (up to 40 nmol ml-1 diluted antiserum). Control sections treated as in (1) to (3) were devoid of specific gold labelling. In control (4) labelling for either SP or VIP was not diminished by the addition of any other gut peptide including bombesin, a peptide known to share two C-terminal amino acids with SP, and glucagon, secretin or gastric inhibitory polypeptide (GIP), which are structurally related to VIP (see Table 1). Gold-labelled goat IgG was prepared8. Briefly, purified goat anti-rabbit IgG was dialysed against 2 mM borax buffer pH 9.0. Protein aggregates were removed by centrifugation (100,000g for 1 h at 4 °C). The optimal amount of antisera necessary to stabilize the gold solution10 was added dropwise with stirring to the gold solution at room temperature. After 1–2 min stirring a stock solution of bovine serum albumin (BSA) (10% in water) was added to a final concentration of 1%. Unbound proteins were removed by three cycles of centrifugation (14,000g for 1 h at 4 °C in 1% BSA/TBS buffer pH 8.2 + 2 × 10<sup>-2</sup> M sodium azide). The last pellet was resuspended to give a final volume 1/10 that of the original gold solution. For immunocytochemistry a dilution of 1/4 was made in TBS containing 0.2% BSA.

immunocytochemical methods for use on ultrathin sections, such as those using colloidal gold<sup>8,12-14</sup>, which allow the visualization of a specific immunoreaction with minimal loss of ultrastructural detail, will be invaluable in establishing the full heterogeneity of the gut p-type innervation.

SP and VIP antibodies were raised in collaboration with Dr S. R. Bloom (Department of Medicine, Hammersmith Hospital). L.P. is an MRC student. This work was supported by funds from the MRC and Janssen Pharmaceuticals.

# GABA reduces binding of ${}^{3}$ H-methyl $\beta$ -carboline-3-carboxylate to brain benzodiazepine receptors

Claus Braestrup\*† & Mogens Nielsen\*

\* St Hans Mental Hospital, DK-4000 Roskilde, Denmark † A/S Ferrosan, Research Division, 5 Sydmarken, DK-2860 Soeborg, Denmark

Benzodiazepines are thought to exert their pharmacological and clinical effects by interacting with specific receptors on neurones in the central nervous system<sup>1-3</sup>. Originally, only benzodiazepinoid compounds were known to interact with these receptors, but recently other classes of agents have been discovered which have high affinity for benzodiazepine receptors4. A representative from one of these classes, ethyl  $\beta$ -carboline-3carboxylate ( $\beta$ -CCE), was obtained from human urine by virtue of its high affinity for benzodiazepine receptors. It was hypothesized that derivatives or congeners of this  $\beta$ -carboline could be related to presumed endogenous ligands, the exact nature of which are unknown<sup>3,5</sup>. Another ester of β-carboline-3-carboxylic acid, the propyl ester, PrCC, has recently been used as a radioligand for labelling benzodiazepine receptors6: in particular, <sup>3</sup>H-PrCC has been observed selectively to label a BZ<sub>1</sub> receptor subclass7. Binding of PrCC to benzodiazepine receptors, however, was less enhanced by  $\gamma$ -aminobutyric acid (GABA) than expected<sup>6,8</sup>. The affinity of benzodiazepines for benzodiazepine receptors is enhanced two to threefold by GABA<sup>9-11</sup>, probably reflecting the functional coupling of benzodiazepine receptors and GABA receptors at the molecular level. Here we have investigated binding of the methyl ester of  $\beta$ -carboline-3-carboxylic acid ( $\beta$ -CCM), which by itself is a convulsant, in contrast to  $\beta$ -CCE and PrCC. We report that <sup>3</sup>H-β-CCM binds to brain benzodiazepine receptors and that, in contrast to binding of <sup>3</sup>H-diazepam, <sup>3</sup>H-β-CCM binding is reduced by GABA in a bicuculline-sensitive manner.

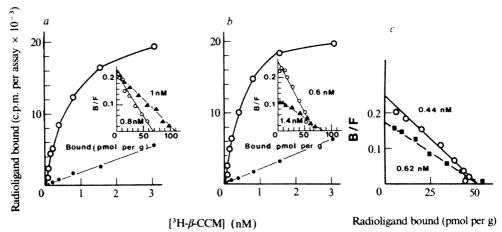

<sup>3</sup>H-β-CCM bound readily to membranes prepared from rat forebrain, hippocampus and cerebellum. Equilibrium was achieved in 10 min at 0 °C and did not change for at least 80 min (data not shown). Specific binding of <sup>3</sup>H-β-CCM was defined as

the difference between total binding and nonspecific binding, which is binding in the presence of a surplus of unlabelled diazepam  $(3\times10^{-6}\,\mathrm{M})$ . By using a benzodiazepine instead of a  $\beta$ -carboline to define nonspecific binding, we excluded interference from presumed ' $\beta$ -carboline sites', unrelated to benzodiazepine receptors. Scatchard analyses of saturation data yielded apparently straight lines (Fig. 1), indicating binding to single classes of sites having affinity constants of  $0.4-0.8\,\mathrm{nM}$ . The values obtained for  $K_D$  are in reasonable agreement with the  $K_I$  value = 1.4 nM for inhibition by  $\beta$ -CCM of <sup>3</sup>H-flunitrazepam (<sup>3</sup>H-FNM) binding in rat cerebellum<sup>7</sup>.

The number of binding sites for <sup>3</sup>H-β-CCM in crude rat cerebellar membranes averaged 56±5 pmol per g tissue  $(\text{mean} \pm \text{s.e.m.}, n = 4)$  which is only 20% less than the number of  $^{3}$ H-FNM binding sites (71 ± 6 pmol per g tissue; mean ± s.e.m., n=3). In the rat hippocampus, however, the number of binding sites for  ${}^{3}\text{H-}\beta\text{-CCM}$  (63 ± 2 pmol per g tissue) was 42% less than that of  ${}^{3}H$ -FNM binding sites (108 ± 4 pmol per g tissue; mean ± s.e.m., n = 3). This is similar to the situation for the radioligand <sup>3</sup>H-PrCC, which was interpreted as <sup>3</sup>H-PrCC binding preferentially to a  $BZ_1$  benzodiazepine receptor subclass<sup>7</sup>. The pharmacological selectivity of <sup>3</sup>H-β-CCM binding sites was very similar to that of <sup>3</sup>H-diazepam and <sup>3</sup>H-PrCC binding sites<sup>1,6</sup> only those agents that act on benzodiazepine receptors inhibit specific <sup>3</sup>H-β-CCM binding and do so at appropriate concentrations (Table 1). These results, together with the chemical similarity of <sup>3</sup>H-β-CCM to the more closely examined <sup>3</sup>H-PrCC<sup>6,7</sup>, suggests that <sup>3</sup>H-β-CCM labels brain BZ receptors, probably with preference for the BZ<sub>1</sub> receptor subclass.

Our main purpose here was to investigate whether  ${}^{3}$ H- $\beta$ -CCM binding was sensitive to GABA receptor stimulation.  $\beta$ -CCM was selected for investigation because it produces pentylenetetrazole-like cloniotonic convulsions in 40–50% of male mice when administered alone in doses which occupy CNS benzodiazepine receptors (10–30 mg per kg intraperitoneally (i.p.), unpublished data). The homologue ester,  $\beta$ -CCE, hardly ever induces convulsions in rats or mice. However,  $\beta$ -CCE enhances the convulsant actions of pentylenetetrazol and bicuculline (a proconvulsant action; refs 12–14 and our unpublished observations). Pharmacological effects of PrCC are not easily determined because very little of this agent reaches the brain after i.p. administration; intravenous administration of 50–200 mg per kg does not produce convulsions in male mice (unpublished results).

Fig. 1 Saturation of specific binding of <sup>3</sup>H-β-CCM and <sup>3</sup>H-flunitrazepam (0.06-8 nM) in rat brain membranes. O, Specific <sup>3</sup>H-β-CCM binding; , specific binding of <sup>3</sup>H-β-CCM in the presence of muscimol (10<sup>-5</sup> M); • nonspecific <sup>3</sup>H-β-CCM binding; • specific <sup>3</sup>H-flunitrazepam binding. Binding assays were done essentially as described for <sup>3</sup>H-PrCC<sup>6</sup>. Crude membranes: hippocampus (a) or cerebellum (b) were rapidly removed and homogenized in  $2 \times 10 \text{ ml}$ ice-cold KH<sub>2</sub>PO<sub>4</sub> (25 mM), pH 7.1, for a few seconds in an Ultra-Turrax homogenizer. The homogenate was centrifuged for 15 min at 48,000g and the pellet resuspended (500 ml per g of original tissue) in another portion of ice-cold buffer. Duplicate aliquots (2.5 ml) of this crude membrane suspension (~90 mg protein per g original tissue) were incubated

subtracting nonspecific binding, which is binding in the presence of diazepam (final concentration  $3 \times 10^{-6}$  M) from total binding. After incubation the samples were filtered through Whatman GF/C glass fibre filters and washed immediately with  $3 \times 5$  ml of ice-cold assay buffer. Radioactivity on the filters was determined by conventional liquid scintillation counting in mini-vials.  ${}^{3}$ H-flunitrazepam (85 Ci mmol<sup>-1</sup>; NEN) binding assays were conducted in a volume of 1.1 ml using 2 mg of original tissue. c, Washed membranes. In experiments designed to investigate the effect of GABA on benzodiazepine receptor binding, an extensively washed, unfrozen tissue preparation was used. Brain tissue (100-1,000 mg) was homogenized using an Ultra-Turrax homogenizer in  $2 \times 10$  ml ice-cold 100 mM Tris-citrate, pH 7.1, and centrifuged for 10 min at 48,000g. The pellet was washed five times in 20 ml Tris-citrate buffer, and each time homogenized and centrifuged as sefore. The final pellet was resuspended (500 ml per g of original tissue) in Krebs-phosphate buffer as indicated ( $\sim 50$  mg of protein per g original tissue). Binding assays were done as described for crude membranes, except that the incubation time was restricted to 20 min at  $0^{\circ}$ C. The Krebs-phosphate buffer contained (final concentration, mM) NaCl (122), KCl (4.8), CaCl<sub>2</sub> (0.97), MgSO<sub>4</sub>,  $7H_2$ O (1.2) and Na<sub>2</sub>HPO<sub>4</sub> (16). Values in a, b and c are from three single experiments, which were all repeated with similar results. Respective  $K_D$  values are shown. B/F, the proportion bound to free radioligand, is expressed as c.p.m. per assay/c.p.m. per assay.

We found that specific binding of <sup>3</sup>H-β-CCM to rat cerebral cortex membranes was reduced in the presence of the GABA agonist muscimol, a finding in clear contrast to the enhancement of <sup>3</sup>H-diazepam binding (Table 2). Muscimol, GABA and the anomalous GABA agonist piperidine-4-sulphonic acid11, similarly reduced specific binding of <sup>3</sup>H-β-CCM in rat cerebellar membranes. The effects of muscimol and GABA, and to a lesser extent of piperidine-4-sulphonic acid (data not shown), were reduced by bicuculline (Table 3). Bicuculline is believed to be a specific GABA antagonist and the results thus indicate that GABA and muscimol reduce <sup>3</sup>H-\beta-CCM binding at least partially by an effect on the GABA receptors. The affinity rather than the number of <sup>3</sup>H-\beta-CCM binding sites was reduced by muscimol (Fig. 1c).  $\beta$ -CCM did not inhibit high-affinity <sup>3</sup>Hmuscimol binding to presumed GABA receptors (unpublished results).

Table 1 Inhibition of specific <sup>3</sup>H-β-CCM binding in rat cerebellum

Inhibitor	IC <sub>50</sub> (nM)
Lorazepam	1
β-CCE	1.5
PrCC	1.5
β-CCM	3
Diazepam	20
CL 218872	50
Norharman	2,000
Ro 5-4864	13,000
Ro 5-3663	200,000
Ethanol	$\sim 2 \times 10^6$
Meprobamate	>30,000
Pentobarbital	>30,000
Diphenylhydantoin	>30,000
Theophylline	>30,000
Strychnine	>30,000
Picrotoxin	>30,000
Pentylenetetrazole	>30,000
Methysergide	>30,000

Crude membranes were used (see Fig. 1 legend) at a concentration of 5 mg original tissue per 2.675 ml of assay; control specific binding was  $6,100\pm250$  c.p.m. per assay (mean  $\pm$  s.e.m., n=5), nonspecific binding was  $600\pm40$  c.p.m. per assay (mean  $\pm$  s.e.m., n=5).  $^3$ H- $\beta$ -CCM was used at a concentration of 0.35 nM, specific activity 76 Ci mmol (NEN). Each IC<sub>50</sub> value shown is the mean of two independent determinations, each obtained by adding five to six concentrations of the agent to duplicate assays. The concentration causing 50% inhibition of specific binding (IC<sub>50</sub> value) was determined graphically. By pairing the two determinations obtained for each of the nine inhibitory agents, the standard deviation was estimated as 25% of the mean value.

Table 2 Effects of muscimol on specific radioligand binding to rat cerebral cortex

		Non-	Specific bindi	ng (c.p.m. per	assay)
Radioligand	Concentration (nM)	specific binding (%)	Without muscimol	With muscimol (10 <sup>-5</sup> M)	%
<sup>3</sup> H-diazepam <sup>3</sup> H-PrCC <sup>3</sup> H-β-CCE <sup>3</sup> H-β-CCM	0.34 0.35 0.29 0.32	21 29 12 17	$517 \pm 3$ $2,712 \pm 210$ $1,686 \pm 130$ $902 \pm 6$	$1,087 \pm 7$ $3,430 \pm 62$ $1,534 \pm 19$ $746 \pm 2$	210* 126† 91 83*

Tris-citrate buffer was used both for washings and assays; for further details see Fig. 1 legend. Nonspecific binding is shown as a % of total binding in the group 'without muscimol'. Absolute values for nonspecific binding in the group 'with muscimol' were indistinguishable from those in the group 'without muscimol'.  $^3$ H-PrCC is  $^3$ H-propyl  $\beta$ -carboline-3-carboxylate (40 Ci mmol $^{-1}$ ; A/S Ferrosan). Lower values from nonspecific binding were obtained using fresh batches of  $^3$ H-PrCC, for example, NET 703 (NEN).  $^3$ H- $\beta$ -CCE is ethyl  $\beta$ -[6(n)- $^3$ H]carboline-3-carboxylate (24.6 Ci mmol $^{-1}$ ). Values shown are for a single experiment, which was repeated with similar results. Specific binding is given as mean  $\pm$ s.e.m. of three values.

Washed rat cerebellar membranes were resuspended in Krebsphosphate buffer for assays using 0.37 nM  $^3$ H- $\beta$ -CCM (76 Ci mmol $^{-1}$ ) as described in Fig. 1 legend. The amounts of original tissue used in experiments 1 and 2 were 5 and 8 mg, respectively, per 2.675 ml of assay. Nonspecific binding in the presence of diazepam ( $3 \times 10^{-6}$  M) was 14% of total binding.

\* P < 0.001; ‡ P < 0.01 compared with control (Student's *t*-test). † P < 0.01; § P < 0.04; || P < 0.001 compared with GABA or muscimol alone (Student's *t*-test).

In another series of experiments we investigated the effect of muscimol on inhibition of specific  ${}^3\text{H-}\beta\text{-CCM}$  binding by flunitrazepam. The 50% inhibitory concentration (IC<sub>50</sub>) for flunitrazepam was 5.9 nM in the absence of muscimol, compared with 2.7 nM in the presence of muscimol ( $10^{-5}$  M) (washed rat cerebellar membranes were used, as described in Fig. 1 legend). On the other hand, inhibition of  ${}^3\text{H-}\beta\text{-CCM}$  binding by unlabelled  $\beta\text{-CCM}$  was slightly reduced by muscimol (IC<sub>50</sub> of 1.3 and 1.7 nM, respectively, in the absence and presence of muscimol ( $10^{-5}$  M)). This experiment shows that those benzodiazepine receptors to which  ${}^3\text{H-}\beta\text{-CCM}$  bind increase their affinity for a benzodiazepine by GABA receptor stimulation and that  ${}^3\text{H-}\beta\text{-CCM}$  binding sites are indeed coupled to GABA receptors.

Our results are in agreement with the notion that  $\beta$ -carboline-3-carboxylic acid esters bind to benzodiazepine receptors (presumably the BZ1 receptor subclass) and that these benzodiazepine receptors are coupled to GABA receptors. The conformational change in benzodiazepine receptors induced by GABA, however, affects the binding affinity of a convulsive  $\beta$ -carboline in a manner exactly opposite to the affinity of benzodiazepines. Thus the convulsive  $\beta$ -carboline and anticonvulsant benzodiazepines recognize benzodiazepine receptors in different ways. It is tempting to speculate that the sensitivity to GABA reflects 'agonist/antagonist' potentials of benzodiazepine receptor ligands (see also ref. 8). Furthermore, an intermediate class of ligands may exist, the binding of which is mainly unaffected by GABA and which lack obvious pharmacological effects when given alone. The arguments presented here rely mainly on observations made with  $\beta$ -CCM; further studies are needed, ideally including more efficient and biologically stable convulsive ligands.

Financial support for this study was given by H. Lønborg-

Madsen Foundation. We thank Mogens Engelstoft for preparmethyl  $\beta$ -[6(n)-3H]carboline-3-carboxylate and Yamamura for helpful suggestions.

#### ACh release from osmotically shocked synaptosomes refilled with transmitter

M. Israël, B. Lesbats & R. Manaranche

Département de Neurochimie, Laboratoire de Neurobiologie cellulaire, CNRS, 91190 Gif-sur-Yvette, France

It is still uncertain whether or not acetylcholine (ACh) released at the synapse is derived from vesicles. We have recently described a sensitive chemiluminescent technique which allows continuous measurement of ACh release from tissue slices or synaptosomes incubated in the reaction mixture 1,2. From the luminescence obtained when synaptosomes are opened in the reaction mixture by a single freezing and thawing we estimated that 30% of the total ACh of Torpedo electric organ synaptosomes is cytoplasmic. The vesicular ACh compartment which resists freezing and thawing requires a detergent to be liberated. These estimations showed that the ACh compartment considered as cytoplasmic was readily released from stimulated synaptosomes3. If we are dealing with a real, soluble cytoplasmic ACh compartment, it should in principle be possible to recover, in controlled ionic conditions, a calcium-dependent ACh release from synaptosomes emptied by an osmotic shock, and refilled at the desired ACh concentration. We show here that this is the case. These results suggest the possibility of a non-vesicular release of ACh from the nerve terminal.

Torpedo electric organ synaptosomes were prepared4.5 and concentrated in a physiological solution of 1.1 osmol. After inhibiting acetylcholinesterase using phospholine  $(0.8 \times 10^{-3})$  for 30 min), the synaptosomes were given an osmotic shock in a large volume of hypotonic solution containing 25 mM K<sub>2</sub>SO<sub>4</sub>, 10 mM Tris-HCl pH 6.9, 0.3 mm ATP, 0.3 mM MgCl<sub>2</sub> and a range of ACh concentrations (0-40 mM). Glycine was substituted for ACh at the lower ACh concentrations. After 30 min, the shock period was ended by adding a KCl solution (300 mM

Table 1 Ionophore plus Ca2+ required for ACh release

Ionophore A23187 (without Ca <sup>2+</sup> )	ACh release (amplitude of trace in pmol) 1.25±0.42
Ca <sup>2+</sup> (without ionophore A23187)	$3.00 \pm 0.5$
Ionophore A23187 + Ca <sup>2+</sup>	(3) 11.2±2.7 (12)

The ACh release induced by ionophore + Ca2+ is significantly different from that in non-release conditions, in which either calcium or ionophore are omitted: 0.01 < P < 0.001. No. of determinations is shown in parentheses.

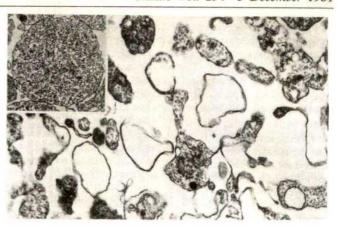

Fig. 1 Synaptosomal sacs. The sacs are either empty or contain glycogen-like granules. Synaptic vesicles are lost during preparation. ×30,800. The insert shows for comparison a synaptosome before shock. Note the numerous synaptic vesicles and the difference in size. ×10,450.

final concentration) which also contained ACh and glycine to maintain the concentrations of these substances. After 30 min, the refilled synaptosomal sacs, equilibrated with ACh and KCl, were centrifuged (27,000g, 30 min), resuspended and sedimented again, before placing them in an 'external medium' consisting of 300 mM NaCl, 25 mM Na2SO4 and 10 mM Tris-HCl pH 8.6. (The alkaline pH necessary for the luminescent reaction did not affect ACh release, as we had previously ensured that the electrical discharge of the tissue remained constant for 3 h at that pH2.) The refilled synaptosomal sacs were resuspended in 100 µl of external medium; 10 or 20 µl were used per assay (this gives ~1 nmol entrapped ACh when the sacs are filled with 40 mM ACh). Considering that these sacs derive from 400 mg of tissue, and that the initial synaptosomal ACh content was  $\sim$ 15 nmol, the yield of this procedure is  $\sim$ 6%.

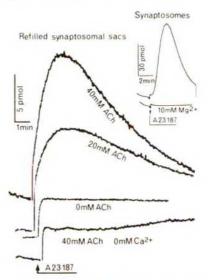

Fig. 2 ACh release from refilled synaptosomal sacs. The synaptosomes were osmotically shocked at 20 °C and refilled with a range of ACh concentrations. The release of ACh triggered by the calcium ionophore A23187 (3.8 µM) increased in proportion to the indicated ACh concentration used to refill the sacs. The omission of calcium greatly reduced ACh release. The insert shows the release of ACh from intact synaptosomes containing ~1 nmol ACh (similar to that from synaptosomal sacs filled with 40 mM ACh). The release from synaptosomes was much reduced (lower trace) when magnesium replaced calcium. The release curve for synaptosomes is comparable to that for refilled synaptosomal sacs. The reaction mixture consisted of 470 µl external medium, with or without 10 mM CaCl2, 2.6 units choline oxidase (Wako), 10 µg horseradish peroxidase type II (Sigma), 10 µl luminol (1 mM; Merck) and 1.7 units acetylcholinesterase from Electrophorus (Boehringer) passed through Sephadex G-50.

The amount of entrapped ACh was, as expected, proportional to the ACh concentration used to refill the shocked synaptosomes. This was verified by disrupting the sacs in the reaction mixture with Triton X-100. Most (85%) of the entrapped ACh was liberated by freezing and thawing the refilled synaptosomal sacs, in contrast to intact synaptosomes where most of the ACh (70%) is bound to synaptic vesicles, resists freezing and thawing and requires a detergent or an osmotic shock to be liberated. A morphological analysis of the refilled synaptosomal sacs showed that the synaptosomes had indeed lost their structure during the procedure (see Fig. 1). The sacs lost their synaptic veiscles but not all were empty as some retained a reticulum-like network and glycogen-like granular material.

Substantial ACh release from the refilled synaptosomal sacs was observed after calcium influx had been triggered by the calcium ionophore A 23187. This release of ACh increased in proportion to the internal ACh concentration (Figs 2, 3a). For comparison, the release of ACh from intact synaptosomes containing ~1 nmol ACh (similar to the sample of sacs filled with 40 mM ACh) is shown in Fig. 2 insert. For both cases the release curves were very similar. To measure the proportion of ACh content of the sac that was released as a result of the calcium influx, we estimated ACh content before and after triggering the release by disrupting the sacs with Triton X-100. Their ACh content declined by as much as 50% in 10 min, at which time the release curve still represents 25% of its maximum amplitude. The specificity for ACh of the release process was tested by filling the sacs with choline. In this case there was a 70% reduction in release, indicating a clear preference for ACh (see Fig. 3a). The calcium dependency of transmitter release from synaptosomal sacs refilled with 40 mM ACh is shown in Fig. 2 (lower trace). There was no release when ionophore was added in the absence of calcium. When extracellular calcium was increased, the ionophore became efficient (Fig. 2, upper trace). The amplitude of ACh release triggered by the ionophore clearly increased when the extracellular calcium concentration was increased (Fig. 3b).

Gramicidin D, which triggers ACh release from intact synaptosomes<sup>3</sup>, also acted on the synaptosomal sacs, which released ACh in proportion to their content. In both cases the release of

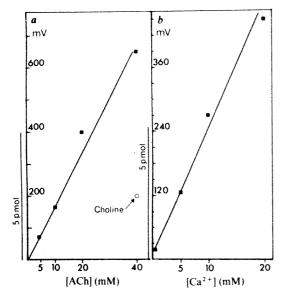

Fig. 3. a, Effect of internal ACh concentration on its release from synaptosomal sacs. The amplitude of ACh release curves is plotted for the various ACh concentrations used to refill the shocked synaptosomes. ACh release was triggered by the calcium ionophore as in Fig. 2. Note that when choline was substituted for ACh (o), release was much reduced. b, Effect of external calcium on amplitude of ACh release. Synaptosomal sacs filled with 40 mM ACh were treated with ionophore A23187 at various extracellular calcium concentrations. The amplitude of release curves increased in proportion to extracellular calcium concentration

ACh was much depressed when magnesium was substituted for calcium.

To determine whether the pH gradient (acid in the sac) was involved in the observed ACh release, we repeated the experiment shown in Fig. 2 at a constant pH(7.9) inside and outside the sac. When ionophore A23187 was added in the absence of calcium, there was no significant ACh release but this was triggered by the subsequent addition of calcium. If calcium was added in the absence of ionophore, only a small amount of ACh was released and the subsequent addition of ionophore A23187 triggered the usual ACh release (Fig. 2). Table 1 gives the mean amplitude of the ACh release curve compared with that for non-release conditions. It is clear that ACh release from the sacs is calcium dependent, even at constant pH.

In conclusion, we were able to obtain a calcium-dependent ACh release from synaptosomal membrane sacs filled with ACh in controlled ionic conditions. The release of ACh increased in proportion to the internal ACh content and to the external calcium concentrations. This model might serve as a means of studying release of cytoplasmic ACh recently measured for intact synaptosomes3. We do not exclude the possibility that a vesicular mechanism coexists with the one described here, which cannot be attributed to synaptic vesicles. The intramembrane particles of the presynaptic membrane, which undergo important changes during synaptic activity<sup>6,7</sup>, may play a prominent part in release of cytoplasmic ACh.

#### Persistent behavioural effect of apomorphine in 6-hydroxydopamine-lesioned rats

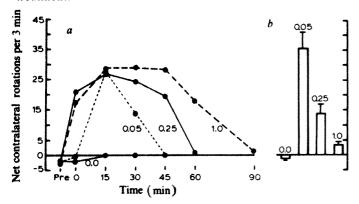

#### Peter B. Silverman & Beng T. Ho

Neurochemistry and Neuropharmacology Research Section, Texas Research Institute of Mental Sciences, Houston, Texas 77030, USA

The rotational (circling) behaviour of rodents with unilateral nigrostriatal damage has been used extensively to investigate nigrostriatal function and the action of dopaminergic compounds<sup>1</sup>. Rats lesioned by unilateral microinjection of the catecholaminergic neurotoxin, 6-hydroxydopamine OHDA), spontaneously exhibit slight ipsilateral (towards the lesioned side) rotation. Systemic challenge with the dopamine receptor agonist apomorphine induces active contralateral rotation, apparently as a result of supersensitivity in the lesioned hemisphere2,3. We report here that apomorphine treatment also results in an extraordinarily persistent change in spontaneous (undrugged) rotation. After one treatment with 50 µg per kg apomorphine, exposure to the rotation environment resulted in a brief, intense burst of contralateral rotation. This behaviour, apparent for months after drug treatment, did not fully develop until 2 weeks after treatment and was never observed in lesioned, but otherwise drug-naive rats. The latent apomorphine effect, unlike the acute effect, was inversely related to dose over the range tested. The behaviour was relatively specific for the environment in which drug treatment had occurred, suggesting a role for learning, but it is difficult to reconcile the inverse dose-response function, lack of recency effect and inability to induce an analogous phenomenon using (+)amphetamine with this explanation.

Male Sprague-Dawley rats (180-240 g) were lesioned unilaterally by injection of 8 µg (base) 6-OHDA hydrobromide (Aldrich). Two to four weeks later rats were injected subcutaneously (s.c.) with saline or apomorphine HCl (0.05, 0.25 or 1.0 mg per kg; Merck). Each rat was placed in a clear plastic hemispherical bowl (26 cm diameter) and observed for 3-min periods before injection, immediately after injection, and periodically thereafter until rotation had slowed to near zero. Total 360° turns in each direction were counted during each observation period. Net contralateral turns were calculated by subtracting the number of ipsilateral turns from the number of contralateral turns. Rats which made fewer than 10 net contralateral turns in one of the observation periods after apomorphine treatment were considered to be only poorly lesioned (<15% of subjects) and their data were disregarded.

Before injection, all groups exhibited slight ipsilateral bias (Fig. 1a). Shortly after apomorphine injection, rapid contralateral rotation began, in the virtual absence of ipsilateral turning. Consistent with previous reports<sup>2,4</sup>, this acute effect of apomorphine was dose-related with respect to duration but dose-independent with respect to peak rate. When placed in the bowl 2 weeks after treatment, in a 3-min observation period rats that had received saline continued to show slight ipsilateral bias whereas apomorphine-treated rats showed almost exclusive contralateral rotation, which was inversely related to the previously administered dose (Fig. 1b). In the case of the group receiving the lowest dose, the rate of rotation in the 3-min observation period 2 weeks after drug treatment was, remarkably, higher than the peak rate observed immediately after drug administration. The animals rotated in tight circles, most rapidly in the first minute, and soon slowed, usually stopping by the end of the 3-min test; no ipsilateral turns were made. Some of the rats treated with saline, 0.05 or 1.0 mg per kg apomorphine were repeatedly tested for rotation at 2-8-week intervals with no further drug treatment. Behaviour of these subgroups was consistent with that shown in Fig. 1b for as long as it was tested: saline-treated rats continued to exhibit slight ipsilateral bias. and rats treated with 0.05 mg per kg apomorphine continued to exhibit rapid contralateral rotation, up to 9 months after treatment. Rats treated with 1.0 mg per kg apomorphine continued to exhibit only slight contralateral rotation up to 14 weeks after treatment.

Acute and long-term rotational response to saline or apomorphine (0.05, 0.25 or 1.0 mg per kg) in 6-OHDA-lesioned rats. 6-OHDA (8 µg base in 4 µl saline and 0.1% ascorbic acid) was injected at a rate of 0.33 µl min<sup>-1</sup> into 180-240-g rats anaesthetized with pentobarbital. Coordinates (with incisor and ear bars levelled) were 4.2 mm posterior and 1.4 mm lateral from bregma, 8.0 mm deep from skull surface. A single s.c. injection of apomorphine HCl or saline was administered 2-4 weeks post-lesion (n = 10-14 per group). a, Mean net contralateral rotations made in 3-min observation periods before injection (Pre), and at the indicated times after injection of saline or apomorphine. b, Mean +s.e.m. net contralateral rotations made 2 weeks after saline or apomorphine treatment when rats were placed in the rotation bowl for a 3-min observational period. All groups except the salinetreated showed a significant difference in rotation 2 weeks after treatment compared with spontaneous rotation before treatment (paired Student's t-tests, P < 0.001 in each case). The effect of each dose of apomorphine measured 2 weeks after treatment was significantly different from the effect of each of the other doses (one-way analysis of variance followed by Student-Newman-Keuls test, P < 0.05 in each case).

Table 1 Persistent rotational response to apomorphine HCl (0.05 mg per kg) in 6-OHDA-lesioned rats as a function of time interval between drug administration and re-exposure to rotation environment

No. of animals	Acute rotational response*	Interval between injection and test (days)	Latent rotational response†
11	$28.3 \pm 4.0$	1	$9.5 \pm 3.0$
8	$27.2 \pm 3.9$	4	$11.4 \pm 4.1$
7	$27.8 \pm 1.9$	7	$12.0 \pm 2.1$
7	$27.1 \pm 2.5$	14	$37.8 \pm 7.1 \ddagger$
9	$26.9 \pm 3.0$	28	$33.7 \pm 7.5 \ddagger$

- \* Contralateral rotations per 3 min beginning 15 min post-injection (no insilateral turns were made).
- † Net contralateral rotations per 3 min on the days indicated (all groups averaged <1 ipsilateral turn).
- $\ddagger$  Significantly different from 1, 4 and 7 day groups (P < 0.025; one-way analysis of variance and Student-Newman-Keuls test).

An additional group of lesioned rats (n = 5) was injected with saline before being placed in the bowl for 48 min; after 2 h they were injected with 0.05 mg per kg apomorphine and observed to rotate in their home cages. This group failed to exhibit contralateral rotation when tested in the bowl from 2 to 24 weeks after treatment. Some of these subjects occasionally showed sudden contralateral rotation when returned from the bowl to their home cages. This stimulus (environmental) specificity was tested further in two groups of lesioned rats. Two weeks post-lesion, rats were treated with 0.05 mg per kg apomorphine on three consecutive days. After each injection, subjects were placed in the bowl (n = 5) or in a rectangular  $(20 \times 21 \times 24 \text{ cm})$  opaque plastic box (n = 5) for 48 min. Two weeks after the last drug treatment, rats that had rotated in the bowl were tested for 3 min in the box and, 30 min later, for 3 min in the bowl. Conversely, rats that had rotated in the box were tested first in the bowl, then in the box. Rats showed significantly greater rotation in the environment in which they had previously received drug treatment than in the novel environment (mean =  $36.6 \pm 9.6$  to  $3.3 \pm$ 2.3 net contralateral rotations per 3 min; P < 0.02; paired Student's t-test).

As the stimulus specificity of the behaviour suggested a role for learning, five groups of lesioned rats were tested for recency effect. Two weeks post-lesion, rats were treated once with 0.05 mg per kg apomorphine and were observed to rotate in the bowl as described for the dose-response experiment. Rats were then placed in the bowls for a 3-min observation period 1, 4, 7, 14 or 28 days after drug treatment. Each rat was thus re-exposed to the rotation bowl only once after drug treatment. Groups tested 14 or 28 days after drug treatment showed significantly greater contralateral rotation than those tested at *shorter* intervals after treatment (Table 1).

Ungerstedt<sup>5,6</sup> reported that some 6-OHDA-lesioned rats developed 'explosive' contralateral rotation at ~2 weeks post-lesion. As the aetiology was unknown, this was termed 'paradoxical' rotation. We consider that paradoxical rotation and the latent, persistent effect of apomorphine shown here are, in fact, the same phenomenon. We have never observed paradoxical rotation in over 200 lesioned, but otherwise drugnaive, rats at 2 to 30 weeks post-lesion. In rats that had been lesioned 30 weeks previously, it was still possible to induce paradoxical rotation by apomorphine treatment.

The stimulus specificity of paradoxical rotation suggests that it may be an extraordinary example of associative learning. If so, it is difficult to explain the inverse dose relationship and lack of recency effect. Furthermore, associative learning alone would not predict any pharmacological specificity, that is, any compound inducing acute rotation, regardless of direction, might be expected to induce a similar latent, persistent rotation. LSD, which, like apomorphine, induces acute contralateral rotation<sup>7</sup>, also resulted in paradoxical rotation after a single treatment (unpublished data). However, we have been unable to induce an analogous phenomenon with either single or repeated

(+)amphetamine treatments, which induced acute ipsilateral rotation.

Just as associative learning does not seem to fully explain our data, we know no previously described effect of apomorphine that would. The effects of low doses of apomorphine have been associated with presynaptic activity8-10. While apomorphineinduced rotation in 6-OHDA-lesioned rats has usually been attributed to direct action on supersensitive striatal neurones, a role in this behaviour has recently been ascribed to drug action in the substantia nigra itself11. It may be that in rats having nigrostriatal 6-OHDA lesions, the presynaptic effect of a small dose of apomorphine is greatly exaggerated over that in intact rats. Paradoxical rotation may then be the result of both learning and a persistent biochemical consequence of drug adminis-

Our finding that paradoxical rotation results from a single treatment with apomorphine should serve as a caveat to those who routinely verify lesions behaviourally by administering a 'screening' dose of apomorphine. Paradoxical rotation may, however, prove useful for studying chronic effects of acute phychoactive drug administration, for example, phenomena such as LSD flashbacks12

We thank May Bain and Steve Strawn for assistance.

Microtubules are a key cytoskeletal constituent of the eukaryotic cell, being involved in mitosis, cell division, cell shape, intracellular transport and motility<sup>1</sup>. They are composed of tubulin, a 110,000-molecular weight  $(M_r)$  protein which is a dimer of 55,000- $M_r$   $\alpha$  and  $\beta$  submits<sup>2</sup>. Multiple forms of both  $\alpha$ and  $\beta$ -tubulin have been demonstrated biochemically by gel electrophoresis<sup>3,4</sup>, column chromatography<sup>5</sup> and peptide maps<sup>6</sup>; immunologically by monoclonal antibodies<sup>7</sup>; and genetically by mapping multiple tubulin genes in the eukaryotic genome There is evidence for multiple tubulin mRNA species 11,12,13, but some of the microheterogeneity may also arise from posttranslational modifications such as phosphorylation14 and glycosylation15. Tubulin microheterogeneity is most dramatic in the brain where it could be the result of cellular heterogeneity or a multiplicity of specific functions within each cell, such as neurite extension and axoplasmic transport<sup>1,16</sup>. Functional specificity has been demonstrated in particular tubulin subunits in other tissues<sup>9,16,17</sup>. To determine whether multiple forms of tubulin coexist in single cells, we have purified and characterized the tubulin of single, isolated sympathetic neurones grown in

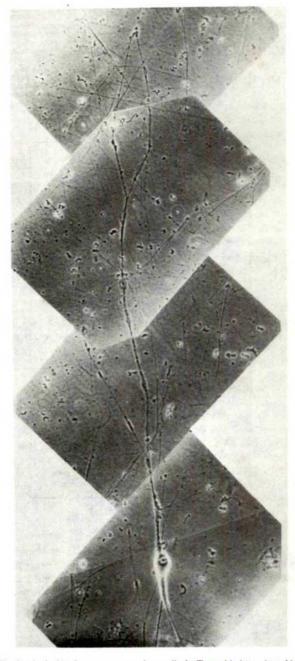

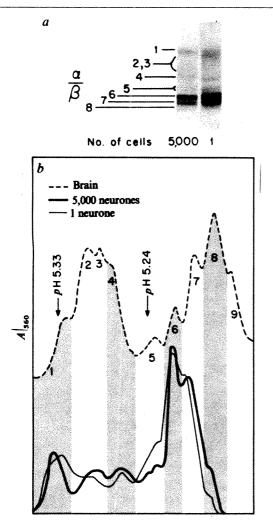

Fig. 1 An isolated neurone grown in a well of a Terasaki plate, viewed by phase-contrast microscopy. Scale bar, 40 µm. Neurones from the superior cervical ganglia of newborn rats were grown as described previously Briefly, the ganglia were mechanically dissociated and the cells plated on to collagen in a medium containing nerve growth factor (NGF). Cultures were kept in a 5% CO2 atmosphere in medium containing 20mM K+. For studies of solitary neurones, Falcon Terasaki tissue culture plates were prepared as follows. The bottom of each well was coated with  $1~\mu l$  of solubilized collagen and the dish exposed to ammonia vapours. The resulting collagen gels provide a more adhesive surface than dried films of collagen<sup>27</sup>. Medium (10 μl) was added to each well, and the dish was sterilized by exposure to UV light. Ganglia were dissociated first with forceps, passed 10 times through a 23G hypodermic needle, then seeded into the dish (<100 cells) in 6 ml of culture medium. In successful platings, each plate had three or four wells with isolated neurones (out of a total of 60 wells), the rest of the wells containing none or only small clumps of neurones. Medium was changed every 3 or 4 days.

primary cell culture18. We show here for the first time that tubulin can be isolated and characterized from a single mammalian neurone. Single neurones exhibit multiple tubulin isoelectric forms, suggesting that structurally different forms of microtubules have functionally different roles in a single cell.

Single neurones grown in microwells of Terasaki plates showed extensive morphological differentiation after 3 weeks in culture. Figure 1 shows a phase-contrast micrograph of a single cell in an isolated well. The cell has well-defined dendritic and

axonal processes. Each cell was labelled with <sup>35</sup>S-methionine for 18 h and radioactive tubulin isolated by vinblastine precipitation in the presence of unlabelled brain carrier, then subjected to isoelectric focusing and autoradiography. Figure 2 shows that a

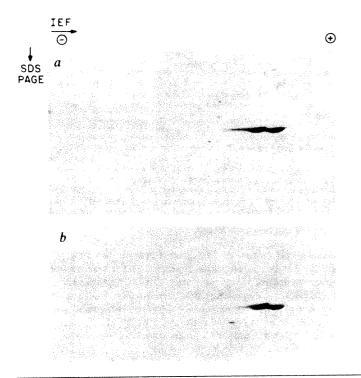

Migration ( Imm)

Fig. 2 Multiple tubulin forms are found in a single neurone. Mature cells (3–4 weeks in culture) were labelled with <sup>35</sup>S-methionine (900–1, 000 Ci mmol<sup>-1</sup>, 6–8 mCi ml<sup>-1</sup>; Amersham) as follows. Mass cultures of 2,000– 5,000 cells were incubated for 18 h in 40 µl of methionine-deficient L-15 culture medium (Gibco) containing 10 µM cold methionine and 1 µM <sup>15</sup>S-methionine. Cultures were collected and sonicated for 3 min in a bath sonicator (Laboratory Supplies, New York) in the presence of 250 µl of 0.24 M sucrose, 10 mM Na-phosphate buffer pH 7.4, 10 mM MgCl<sub>2</sub>, 0.2 mM GTP and 100 µl of brain homogenate prepared from mature rat brain in 2 vol of the same buffer. The resulting homogenates were centrifuged first at 12,000 g for 10 min and then at 100,000 g for 1 h. Vinblastine sulphate (1 mg ml-1) was added to the high-speed supernatants. Samples were incubated at 37 °C for 30 min, then the tubulin aggregates were sedimented at 5,000 g for 5 min. The tubulin-enriched pellets<sup>28</sup> were each suspended in  $50 \,\mu$ l of lysis buffer<sup>29</sup> and  $10 \,\mu$ l aliquots were subjected to isoelectric focusing<sup>29</sup>. Single cells in microwells of Terasaki tissue culture plates were incubated in 10  $\mu$ l of methionine-deficient medium containing 10  $\mu$ M <sup>35</sup>S-methionine for 18 h. They were then collected in 50  $\mu$ l of the buffer used for the mass cultures plus 0.5% Triton X-100 and were sonicated in the presence of 20 µl of brain homogenate. (The addition of Triton X-100 did not interfere with subsequent experimental procedures.) Vinblastine precipitation and isoelectric focusing were performed as above, except that all the material obtained from a single cell was applied to one isoelectric focusing gel. The final pH gradient was determined by eluting 2-mm portions of a blank gel in 10ml H<sub>2</sub>O. Gels were stained, dried and exposed to Kodak X-R5 X-ray film and Dupont Cronex lighting-plus intensifying screens<sup>30</sup> for weeks, depending on the amount of label present. The numbers identifying the various isotubulin bands were assigned by alignment with Coomassie brilliant blue staining of the rat brain tubulin carrier. a Autoradiogram of the isoelectric focusing gels; b, densitometric tracings of the autoradiogram shown in a. Shaded areas were divided according to the peaks of the isotubulin bands of the sympathetic neurones and aligned with the co-migrating brain carrier. Nine isotubulins are observed in the brain tubulin; 1-4 comprise the classically defined  $\alpha$ -tubulin subunit, and 5-9 the β subunit<sup>3</sup>. The co-electrophoresed cold carrier brain tubulin and radiolabelled cultured neuronal tubulin show different proportions of the various isotubulins, which shows that the isoelectric focusing patterns are not artefacts of discontinuities in the ampholine pH gradient. Previous reports have established that brain tubulin microheterogeniety does not arise from proteolysis during purification. As the carrier brain isotubulin pattern is unaltered in the presence or absence of sympathetic neurone extract (data not shown), degradation during the purification procedure by proteases derived from the neurones is unlikely. Densitometric traces analysed by planimetry revealed  $67\pm4\%$   $\beta$ -tubulin and  $33\pm4\%$   $\alpha$ -tubulin in the vinblastine precipitates of high-speed supernatants of cultured neurones. When these values are corrected for methionine content (11 for  $\alpha$ , 19 for  $\beta$ )<sup>31–33</sup> of the tubulin, we obtain a ratio for  $\alpha/\beta$  close to the 1:1 ratio of  $\alpha$ - to  $\beta$ -tubulin

single neurone expresses up to seven isotubulins in a pattern very similar to that expressed by mass cultures of 5,000 cells.

found in nonradioactive precipitants from rat brain.

We performed several experiments which demonstrated that the isotubulin patterns obtained by one-dimensional isoelectric

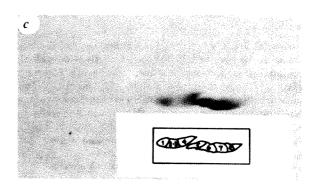

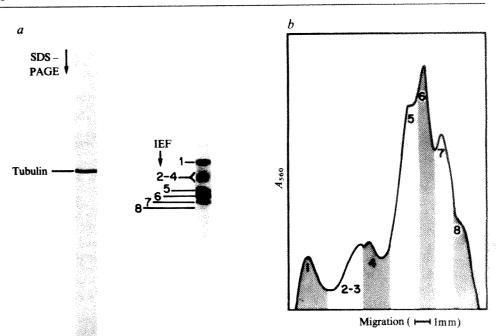

Fig. 3 Two-dimensional polyacrylamide gel electrophoresis (PAGE) of tubulin purified by vinblastine precipitation. The isoelectric focusing gels of mass culture tubulin (Fig. 2) were subjected to electrophoresis in SDS on a gradient of 7-17% polyacrylamide in the second dimension? Gels were stained with Coomassie brilliant blue, dried and autoradiographed as described in Fig. 2 legend. a, Coomassi brilliant blue stain of the cold carrier. The contribution of sympathetic neurone tubulin to the stained cold carrier brain tubulin is at the most 5-10% (0.5  $\mu$ g from the cultures/5-10  $\mu$ g of cold carrier). b, Autoradiogram of the 35S-labelled neuronal tubulin of the same gel shown in a; 24 h exposure. c, Same as b, but a 4-h exposure; enlarged 3 ×. Inset, spots were numbered by visual inspection. The relative intensities of the spots correspond to the intensities of the isoelectric focusing bands numbered in Fig. 2.

Fig. 4 Tubulin microheterogeneity in sympathetic neurones is independent of the method of purification used. 35S-methionine-labelled tubulin was isolated by DEAE-cellulose chromatography. Mature cells (3-4 weeks in culture) were labelled with <sup>35</sup>Sculture) were labelled with methionine (100  $\mu$ Ci per plate of 2,000–5,000 cells). Cells from five culture plates were collected and mixed with 1.5 ml of brain homogenate prepared in 2 vol of 0.24 M sucrose, 2.5 mM MgCl<sub>2</sub> and 50 mM Na-pyro-phosphate pH 7.0. Cells were sonicated as in Fig. 2 and centrifuged at 30,000 g for 30 min. The resulting supernatant was subjected to DEAE-cellulose chromatography for tubulin purification3. a, Purified tubulin was subjected to electrophoresis in SDS on a gradient of 7-17% polyacrylamide (SDS-PAGE) as well as to isoelectric focusing (IEF). b, The isoelectric focusing gels were densitometrically scanned and shaded areas divided as in Fig. 2b.

focusing were not due to contamination by material other than tubulin. Isoelectric focusing and subsequent SDS-polyacrylamide gel electrophoresis on a second dimension (Fig. 3) show that there is considerable tubulin purification by vinblastine precipitation. The gel was scanned in seven consecutive vertical paths within the pH range occupied by the various tubulins, and the optical density quantitated by planimetry. Several faint contaminating proteins together comprised 7.4% of the total optical density, and the remaining 92.6% of the label was judged to be contained in tubulin, by the criteria of molecular weight and isoelectric point. No single contaminating protein comprised >1.3% of the total label, and as no single isotubulin band comprised < 8.1% of the total label, it is clear that none of the isotubulin bands seen after isoelectric focusing can be attributed to contaminants. Moreover, the contaminating spots were detected only after a 24-h exposure, at which time the tubulin bands were over-exposed. A shorter (4 h) exposure (Fig. 3c) reveals multiple tubulin spots corresponding to the isotubulin pattern obtained by isoelectric focusing in one direction (compare with Fig. 2; see also ref. 4); in this exposure most contaminating spots could not be detected (data not shown).

To demonstrate further that tubulin microheterogeneity in sympathetic neurones is independent of the method of purification, tubulin was purified from <sup>35</sup>S-methionine labelled mass cultures by DEAE-cellulose chromatography3. This technique gave >96% pure tubulin as judged by SDS-polyacrylamide gel electrophoresis (Fig. 4a). Isoelectric focusing revealed a similar isotubulin pattern to that found for the vinblastine precipitate (Figs 2 and 4a, b) and showed the presence of at least seven isotubulins.

These data indicate that a single neurone is capable of expressing virtually the whole range of isotubulins expressed by mass cultures. Although the tubulin microheterogeneity found in sympathetic neurones is comparable in extent with that previously found in brain<sup>3,4,7,14-16</sup>, the proportions of the various isotubulins in the cultured neurones are different from those found in the whole brain tubulin carrier (Fig. 2b). For example, isotubulins 2 and 3 are greatly enriched in the tubulin of the whole brain. As sympathetic neurones were grown in the absence of non-neuronal cells, this difference could be due to cell or tissue specificity of tubulin forms. Our data cannot determine whether the different proportions of isotubulins in brain and cultured neurones arise from the absence of glia the elimination of many neurone types, or differences between newly synthesized tubulin in the cultures and the pre-existing tubulin pool in brain.

The existence of multiple tubulin forms in a single neurone

suggests two different hypotheses for specificity in microtubule organization and function: (1) The neurone may have various different forms of microtubules, each containing different isotubulin types. These microtubules may have specialized functions or subcellular distributions. In neurones, the  $\alpha$  subunit class is preferentially associated with synaptic membranes<sup>21</sup> and synaptic vesicles<sup>22</sup>. We have preliminary evidence from neurones grown in a three-chamber culture dish (which separates the cell bodies from axons<sup>23</sup>) that there is an enrichment in the soluble  $\beta$ -tubulin class (isotubulins 5-8) in the axoplasm relative to the cytoplasm as analysed by isoelectric focusing. These results are similar to those of Brady et al.24 who found axonal transport of mainly the classically defined  $\beta$ tubulin by two dimensional gel electrophoresis. In sea urchins, using peptide mapping, Stephens<sup>6</sup> showed that the tubulin subunits of cilia, flagella and cytoplasm have some non-identical peptides, indicating differences in primary structure. (2) Each microtubule in the cell may contain all the isotubulin forms, which may differ by having specific binding sites for regulatory molecules and various subcellular organelles. Microtubule functional specificity may thus result not only from structural differences in the tubulin molecule itself but also from differences in the microtubule associated proteins<sup>25</sup>. Changes in composition and activity of microtubule-associated proteins have been observed during brain development<sup>26</sup> with a time course similar to that of changes in tubulin micro-heterogeneity<sup>3,11</sup>. It will be of interest to see whether the structural differences between the various isotubulins affect the binding of specific associated proteins and correlate with specific microtubule functions in the single cell.

#### E. coli uvrB protein binds to DNA in the presence of uvrA protein

#### Barry M. Kacinski & W. Dean Rupp\*

Departments of Therapeutic Radiology and of Molecular Biophysics & Biochemistry, Yale University School of Medicine, 333 Cedar Street, New Haven, Connecticut 06510, USA

In vivo and in vitro, the endonucleolytic incision of damaged DNA containing pyrimidine dimers or other bulky lesions requires the action of the uvrA, uvrB and uvrC gene products of Escherichia coli<sup>1-3</sup>. To understand better how the products of these three genes mediate incision, all three genes have been cloned4-10. Although the gene products of the three genes (designated UVRA, UVRB and UVRC) are all required at the early stages of nucleotide excision repair, it is not known whether they act independently or together as part of a multiprotein complex. As the three proteins are involved in the repair of damaged DNA, it is reasonable to expect that under some circumstances all three proteins should bind to DNA, and, in accord with this expectation, previous experiments have demonstrated that UVRA and UVRC bind tightly to singlestranded DNA<sup>11-13</sup>. We have investigated whether UVRB is also a DNA-binding protein and report here a radiochemical purification of UVRB and experiments using this radiolabelled UVRB to measure its binding to DNA. By itself, UVRB does not bind strongly to DNA, but in the presence of UVRA, tight binding of UVRB to single-stranded DNA is observed, thus demonstrating the occurrence of direct interactions between UVRA and UVRB.

Fig. 1 SDS gels of the preparations of UVRB and UVRA used in DNA binding experiments. Lane 1, autoradiogram of UVRB. 35S-labelled autoradiogram of UVRD. UVRB was prepared from 21 of 35S-L-·S-(1 μCi methionine) maxicells of strain CSR603 carrying the uvrB plasmid pDR1494. pDR1494 carries the uvrB gene and has been described elsewhere Selective lysis 2.18 was followed by chromatography DEAE Biogel (Biorad) and Biogel HT (Biorad) to yield a preparation containing  $23~\mu g~ml^{-1}$  total protein and  $24,000~c.p.m.~ml^{-1}$  in buffer A (50 mM K-MOPS, 100 mM KCl, 1 mM Na<sub>2</sub>EDTA, 10 mM mercaptoethanol and 25% glycerol). Lane 1 shows the autoradiogram of the SDSgel analysis of 50 µl of this preparation. Lane 2, Coomassie blue-stained gel of the UVRA preparation. UVRA was prepared as described for fraction III in ref. 12 and contained 30 µg protein per ml. Lane 2 shows the Coomassie blue staining pattern of the SDS-gel analysis of 50 µl of this preparation. The subunits of E. coli

β,β' =

RNA polymerase were run as molecular weight markers (165,000, 155,000, 90,000 and 40,000), and their positions in the gel are indicated in the left margin.

We have developed the maxicell procedure for specifically labelling plasmid-encoded proteins, and have used this in combination with transposon inactivation to identify and to purify protein products of cloned genes 7.11,12,14-16. By comparing plasmid-encoded proteins synthesized in maxicells with those synthesized by derivatives in which the uvr genes were inactivated by insertion of a transposon, UVRA, UVRB and UVRC have been identified as polypeptides with molecular weights of 114,000, 84, 000 and 70,000, respectively 11,15

UVRB was labelled in maxicells as described previously15 and was partially purified so that no other labelled proteins are

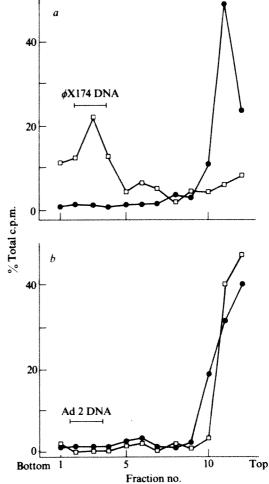

Fig. 2 Binding of radiolabelled UVRB to DNA in the presence of UVRA. 50 µl of the UVRB preparation (Fig. 1, lane 1) is mixed with 0 (●) or 10 µl (□) of the UVRA preparation (Fig. 1, lane 2) with 10 or 0  $\mu$ l buffer A, 7  $\mu$ l 1 M MgSO<sub>4</sub>, 60  $\mu$ l buffer Y (50 mM K-MOPS pH 7.5, 100 mM KCl, 1 mM Na<sub>2</sub>EDTA, 10 mM mercaptoethanol) and 18 µg ФX174 single-stranded circular DNA (a) or adenovirus 2 double-stranded linear DNA (b) in  $60 \mu l$ 10 mM Tris-HCl pH 8.0, 1 mM Na<sub>2</sub>EDTA. Samples were kept at room temperature for 15 min and then applied to 5-20% linear sucrose gradients (5 ml in buffer Y and 20 mM MgSO<sub>4</sub>). The gradients are run for 3h in a Beckman SW50.1 rotor at 45,000 r.p.m. and 25°C after which 0.4 ml fractions are collected and assayed for radioactivity which is plotted above as a function of the gradient fraction. The bar indicates the position of DNA in the gradient.

detected by autoradiography after SDS-gel electrophoresis (Fig. 1). The radiolabelled UVRB was mixed with either singlestranded or double-stranded DNA and sedimented through a sucrose gradient. The results in Fig. 2 show that there is little or no binding to either form of DNA. We then looked for other factors that might cause binding of UVRB to DNA, being particularly interested in learning whether the addition of purified UVRA would have an effect. UVRA was isolated as described elsewhere 12. The Coomassie blue-stained SDS gel (Fig. 1, lane 2) shows that UVRA is the only major stainable protein in this preparation. As seen in Fig. 2, when UVRA is present in the mixture, UVRB co-sediments with the singlestranded DNA. As previous studies showed that UVRA had a high affinity for single-stranded DNA, these results indicate that UVRB probably forms a ternary complex with UVRA and single-stranded DNA, because UVRB co-sediments with ΦX174 single-stranded DNA in the presence, but not in the absence, of added UVRA. This provides a mechanism by which UVRB is in the proximity of damaged parts of a DNA molecule even though by itself the protein does not bind to DNA. These results show that UVRA and UVRB interact with each other and strongly suggest that the two proteins act together rather than independently during nucleotide excision repair. The stoichiometry of this reaction and the role of UVRC and other effectors are under investigation.

#### **Enrichment of satellite DNA** on the nuclear matrix of bovine cells

#### Lloyd H. Matsumoto

Division of Biology and Medicine, Brown University, Providence, Rhode Island 02912, USA

The skeletal framework of the enkaryotic nucleus is a protein matrix1,2 which maintains the physical shape of the nucleus. Attached to the matrix is a fraction of DNA resistant to deoxyribonuclease I (DNase I) digestion. Ribosomal DNA sequences also are enriched on nuclear matrices from rat liver. The question thus arises whether other repeated DNAs are preferentially attached to the nuclear matrix. This question could be resolved if the repeated DNA was available in sufficient quantity for biochemical studies and differed in its physical or sequence characteristics from the rest of the nuclear DNA. The satellite DNAs of bovine cells meet these criteria. Here we show that nuclear matrices from bovine cells are in fact enriched in satellite DNA.

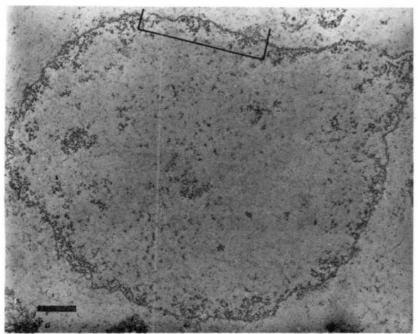

Madin-Darby bovine kidney cells4 were cultured in reinforced Eagle's medium supplemented with 5% fetal calf serum (FCS) and 5% calf serum as previously described<sup>5</sup>. Cells were grown to ~90% confluence on 150-mm Nuncion plates, collected by trypsinization and counted in a haemocytometer. To facilitate nuclear isolation, cells were first incubated for 10 min in a low magnesium buffer: 10 mM Tris-HCl, 0.2 mM MgCl<sub>2</sub> pH 7.4. This and all subsequent nuclear matrix isolation procedures were carried out at 0 °C. Nonidet P-40 (Calbiochem) was added to a final concentration of 1% and the cells were homogenized with 5-10 strokes of a loose-fitting Dounce glass homogenizer. Nuclei were collected by centrifugation at 750g for 8 min and the nuclear pellet resuspended in the low magnesium buffer and again collected by centrifugation. Nuclear matrices were prepared according to the procedure of Pardoll et al.6. Briefly, purified nuclei were resuspended in the low magnesium buffer followed by slow addition of NaCl to a final concentration of 2 M. To this solution was added DNase I (Worthington) to a final concentration of 200 U ml<sup>-1</sup> for 20 min. The matrices were collected from this solution by centrifugation at 2,000g for 15 min. An example of a nuclear matrix isolated in these conditions is shown in Fig. 1.

DNA was extracted from the purified nuclear matrices by resuspending them in 50 mM Tris-HCl, 10 mM NaCl, 10 mM EDTA pH 7.4. T<sub>1</sub> ribonuclease and ribonuclease A (Millipore) were added to final concentrations of 25 U ml-1 and 100 μg ml<sup>-1</sup> , respectively. Matrices were incubated in this solution at 37 °C for 30 min. After RNase treatment, SDS and proteinase K (Boehringer Mannheim) were added to final concentrations of 0.5% and 100  $\mu g$  ml<sup>-1</sup>, respectively; incubation was at 37 °C for an additional 30 min. The residual DNA in this solution was extracted twice with phenol and once with diethyl ether. The solution was adjusted to 0.5 M NaCl and the DNA ethanol-precipitated by the addition of 2 vol 95% ethanol. Typically, the residual nuclear matrices contained ~1% of the total DNA when compared with a theoretical value based on the haploid DNA content of the bovine cell (3.3 pg)<sup>7</sup>

The ethanol-precipitated nuclear matrix DNA was resuspended in 10 mM Tris-HCl pH 8.0. Solid CsCl was added to an aliquot of this DNA to a final density of 1.715 g ml<sup>-1</sup>. The DNA was centrifuged at 39,460 r.p.m. for 18 h in a Beckman model E analytical ultracentrifuge. Micrococcus lysodeikticus DNA  $(\rho_{\text{CoCl}} = 1.731 \text{ g ml}^{-1})$  was used as a marker. Control DNA was centrifuged in a second model E cell at the same time as nuclear matrix DNA. The isolation of control DNA was identical to that of matrix DNA except that high salt-treated nuclear matrices from control cells were not digested with DNase I. The results of analytical ultracentrifugation of both nuclear matrix and control DNA are shown in Fig. 2.

The bovine satellite DNAs comprise ~15% of the total genome. Of the total matrix DNA, ~60% is satellite DNA and 40% main-band DNA—this represents a fourfold enrichment of satellite DNA on the nuclear matrix. All four major bovine satellite DNAs seem to be protected from DNase I digestion (Fig. 2). To corroborate further the enrichment of satellite DNA on the nuclear matrix, a second aliquot of the isolated matrix DNA was digested with EcoRI (see Fig. 3). Fragments characteristic of satellites I (1,400 bp) and IV (970, 1,600 and 2,150 bp) were generated by EcoRI digestion (satellites II and III are undigested by this enzyme<sup>9,10</sup>). The relative enrichment of satellites I and IV is also obvious from the reduction in the background DNA due to main-band contamination (Fig. 3, lanes 2, 3). A reported absence of enrichment of satellite sequences on the nuclear matrix11 may be due to differences in the isolation of matrix-associated DNA compared with methods used here.

A primary role of the nuclear matrix is in DNA replication: the matrix is the site at which DNA replication complexes are fixed<sup>6,12</sup>. DNA is replicated as it moves through the stationary complex13. Unlike that of eukaryotes, the bacterial replication complex is attached to the cell membrane 14-16. The nuclear matrices of SV40-infected 3T3 cells are enriched in SV40

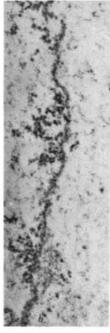

Fig. 1 Electron micrograph of a nuclear matrix from a Madin-Darby bovine kidney cell. Pellets of nuclear matrices were fixed in 3% glutaraldehyde in 0.1 M sodium phosphate buffer pH 7.3, post-fixed in 1% OsO4 and embedded in plastic. Thin sections were stained with uranyl acetate and lead citrate. a, nuclear matrix appears as thin fibrogranular network. Scale bar, 1 µm. b, Enlargement ( $\times 1.8$ ) of the peripheral region marked (black lines) in a. The periphery appears granular. The absence of a nuclear envelope is due to the use of the detergent Nonidet P-40 in the nuclear isolation procedure.

sequences<sup>17</sup>. This association of viral sequences with the matrix may be due to the recognition and binding of the viral origin of replication by the nuclear matrix. Similarly, the tandemly repeated bovine satellite DNAs18 may contain periodically spaced origins of replication which are recognized and bound by the nuclear matrix.

I conclude that bovine satellite DNAs are enriched on the nuclear matrices of interphase cells. Whether this enrichment is due to the preferential association of nuclear matrices with

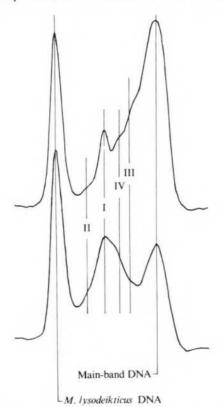

Fig. 2 Analytical ultracentrifugation tracings of control DNA (upper trace) and nuclear matrix DNA (lower trace). The four major density satellites of bovine DNA in CsCl are I = 1.715, II = 1.723, III = 1.705 and IV = 1.710 g ml<sup>-1</sup>. The percentage of the total DNA attributable to satellite or main-band DNA was determined by cutting out and weighing the respective peaks and regions beneath them.

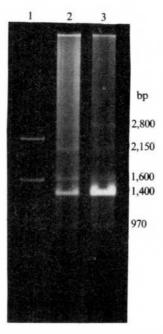

Fig. 3 Gel electrophoresis of EcoRI-digested control DNA (lane 2) and nuclear matrix DNA (lane 3). Electrophoresis was in 1% agarose at 70 V for 5 h in 0.04 M Tris-HCl pH 8.0, 0.02 M sodium acetate, 2 mM EDTA, 0.018 M NaCl. After electrophoresis the gel was stained with 1 µg ml dium bromide, and photo-graphed in UV light. The plasmid pBR322, cut with HincII and AvaI, was added to an aliquot of pBR322 cut with HinfI and used as marker. The EcoRI fragment of satellite I is 1,400 bp; a dimer (2,800 bp) of this satellite is also present. Satellite IV was cut by EcoRI into fragments of 970, 1,600 and 2,150 bp.

origins of replication sequences in satellite DNA or to other satellite DNA sequences is being studied.

This research was supported by American Cancer Society grant CD-76. I thank Norma Messier and Robert Scully for technical assistance and Susan Gerbi for use of her laboratory and for valuable criticisms.

## **JOHN RAY**

Dictionariolum trilingue 1675

Facsimile of the first edition
With an introduction by W. T. Stearn

John Ray, many-sided scholar and supreme British naturalist of the 17th century, produced in 1675 this three-language dictionary in the English of the period, Latin and Greek. Of the eight editions issued between 1675 and 1736 most were literally worn out of existence by constant use and only six copies of the first edition are known to have survived.

The vocabulary lists under 32 subject headings the names of birds and other animals, plants, minerals, ailments, parts of the body, foods, household and farm implements, tools, utensils and much else that Ray thought useful to the learned of his time.

The DICTIONARIOLUM TRILINGUE makes enlightening and entertaining reading for the scholar and layman alike and would make an ideal Christmas present for the discerning reader. £7.50

# Nuclear Radiation in Warfare sipri

This latest book from the Stockholm International Peace Research Institute examines the wide range of methods of exploiting the acute and long-term effects of radiation in nuclear weapons. It documents the various kinds of radiation which result from nuclear explosions and the factors affecting the biological response to radiation. The biological effects of radiation on man are discussed in some detail, and attacks on nuclear power stations, radiological warfare and terrorist activities are also discussed.

#### **Pulsed Neutron Scattering**

C. G. Windsor

Thermal neutron scattering is an important technique which is finding a multitude of applications in solid-state physics, chemistry, biology and technology. This is the first book on pulsed neutron scattering, and is intended as a handbook for those wanting to use this new technique. It provides a wealth of background knowledge on how the sources work and gives full details of all the main pulsed experimental techniques and the analysis of results. It also contains a detailed comparison with reactor performance.

### **Testing for Toxicity**

Edited by J. W. Gorrod

The synthesis of new organic chemicals is taking place at an ever-increasing rate, and it is vitally important that methods for testing for toxicity keep pace. This book describes the regulations governing the testing for toxicological effects of drugs in the EEC, USA, Canada and Japan, and goes on to consider the contemporary value of traditional tests based on acute and chronic exposure of animals to drugs. There follows an examination of tests involving covalent binding, glutathione depletion, protein binding, enzyme levels, immunology, microorganisms and biochemical markers, thus providing an up-to-date overview of the methods available for detecting toxicity produced by drugs or foreign compounds.

November 1981 0 85066 218 4 £18.00

# Reproductive Anthropology: Descent Through Woman

by D.A.M. Gebbie, Ministry of Health and Medical Services, Central Hospital, Honiara, Solomon Islands

The level of perinatal and maternal mortality and morbidity remains high despite the fact that during the last fifty years the practice of obstetrics has become a highly complex science. The number of abnormalities accompanying the supposedly physiological process of childbirth is striking, and in this work the social, environmental and medical factors are discussed in the light of current obstetric knowledge.

Beginning with an historical survey of childbirth practices, the book develops as an intriguing philosophic and scientific study of the interrelationship of childbirth, nutrition and population control.

Contents: Introduction; In the Beginning; Ancient Egypt; Greece and Rome; The Dark and Middle Ages into the Renaissance; The Seventeenth and Eighteenth Centuries; The Nineteenth Century; The Twentieth Century: William Caldwell, Howard Moloy and Herbert Thoms; The Twentieth Century: Other Contributors; An African Interlude; Health and Food; Our Daily Bread: Good and Bad; The Unequal Equation; Population and Sex; Population and Disease; Population and Control; The Original Australians: Their Discovery; The Original Australians: Their Life; The Original Australians: Their Solution; Epilogue; Index.

## Calcium and cAMP as Synarchic Messengers

by H. Rasmussen, Yale University, School of Medicine

Breaks with the traditional view that nerves and muscles are excitable cells that employ calcium to couple stimulus to response, and that liver and kidney, for example, are non-excitable cells that employ cAMP to couple hormone action to cell response, It argues that in nearly all cells stimulus-response coupling employs both calcium and cAMP as interrelated messengers. The name *synarchy* is applied to the universal calcium-cAMP relationships to signify that the two messengers act together to regulate cell function.

#### **Enantiomers, Racemates and Resolutions**

by J. Jacques, College de France;

A. Collet, Laboratoire de Chimie Organique des Hormones, and S.H. Wilen, City University of New York

Analyzes in detail the properties of enantiomers (fusion behavior, solubility, crystallization, distillation, and sublimation), enantiomer mixtures, and racemates. The book also surveys theory and practice of resolutions, considering classical and chromatographic resolutions and those by direct crystallization.

#### **Nutrition and the Killer Diseases**

edited by **M. Winick,** Columbia University College of Physicians and Surgeons

Explores the relationship between nutrition and the three leading killers of adult Americans: atherosclerosis, hypertension, and diabetes.

It provides nutrition and health care professionals with useful guidelines for preventive strategies and therapeutic interventions by examining the importance of nutrition in the etiology of these diseases, including ways in which nutrition acts synergistically with genetic tendencies to allow the expression of disease; surveying new approaches to altering nutritional patterns in order to lower the incidence of these diseases; and discussing the control of diet in the management of the diseases. Current Concepts in Nutrition Vol. 10

# Christmas Books Supplement

# What did you read during 1981?

Sixteen contributors discuss the books they particularly enjoyed

#### Paul Davies

Any book that opens with the challenge "You may well be wondering if this book is going to be too difficult for you" deserves a few minutes perusal. When, a few lines further on, the author implores "please read at least to page 4" only the most sceptical or faint-hearted reader will lose interest.

After a decade of reading, consulting and reviewing books on the theory of relativity, I found Sam Lilley's treatment of the subject in *Discovering Relativity for Yourself* refreshing and entertaining, as well as a gold-mine of heuristic devices. The informality of style conjures up the image of a draughty Nissen hut in Skegness, which is, no doubt, where much of the material originated — Lilley is an expert on teaching relativity to carpenters, miners and housewives at Adult Education classes. A curious amalgam, this book, of American self-paced inquiry and quaint, Old World, good-for-the-soul instruction.

#### Glyn Daniel

The Megalithic Art of Western Europe is a book we have been waiting for ever since earlier works on this subject by Coffey and Le Rouzic. It is a corpus and a commentary, and no serious student of prehistoric Europe in the fourth and third millennia BC can afford to be without it — if they can afford it at £50.

We have also been waiting for years (indeed it seems to have been ten years in the making) for the first volume of the Cambridge Agrarian History of England and Wales. Here it is: Vol.I, Part I Prehistory, edited by Stuart Piggott. The editor himself deals with early prehistory, Peter Fowler covers later prehistory — from the Beaker folk to the Romans — and then there is a survey of some 100 pages on the livestock of southern Britain from prehistory to AD 1042 by Dr M.L. Ryder. This book is essential reading for everyone concerned with ancient Britain.

#### **Ashley Montagu**

LYNN Barber's *The Heyday of Natural History 1820–1870* greatly added to the amenities of 1981. It is an utterly delightful romp through a craze for amateur natural history that lasted for 50 years, but which

on the whole was curiously unaffected by Darwinism.

Elizabeth L. Eisenstein's *The Printing Press as an Agent of Change* is a unique book and the first of its kind. It is extraordinarily illuminating on the role that printing played in the development of science. I found the book utterly enchanting.

The best book I have read in years on the evolution of humankind is Nancy Makepeace Tanner's On Becoming Human. Among its many notable achievements is that it puts the role of women in that development back in its proper place.

#### Eric Ashby

AMONG books published over the year, I select two which are straws in the wind of opinion among biologists. One is Robert Boardman's record of the international movement to conserve nature, *International Organization and the Conservation of Nature*. The other is Rupert Sheldrake's *A New Science of Life*, an astonishing challenge to orthodox theories of plant and animal development.

Boardman provides impressive evidence that tens of millions of people (over three million in Britain alone) are enrolled in a campaign to protect nature from hazards caused by mankind; something inconceivable 50 years ago on this scale. Sheldrake's book recalls the writing on holism 50 years ago by Smuts and Whitehead. But he adds a new dimension: he offers to put his hypothesis to the test of experiment. Boardman confirms our attitude of respect for nature. Sheldrake challenges our respect for reductionism.

#### Stephen Jay Gould

I WILL cheat a bit and delve back a few months into 1980, since I recommend (in any case) a book for all ages. My choice is, of all things, an index — but no ordinary index. It is the last volume of the monumental Dictionary of Scientific Biography, published in 16 parts from 1970 to 1980 with C.C. Gillispie as general editor.

No ordinary, dry accounts of basic facts in the lives of great scientists, these — but intellectual essays (in biographical format) on the social context of science, the nature of creativity and the passion for learning that makes our profession such a joy at its best. Browse and learn.

#### Stuart Sutherland

THIRTY years ago it was customary for experimental psychologists to present new work in book form. The publication of Donald Hebb's The Organization of Behavior in 1949 and of J.J. Gibson's Perception of the Visual World a year later aroused great excitement. Now that psychology has — almost — attained the respectability of a science, those heady days are over. New work appears in journals and most books on the subject merely synthesize existing research.

Of recent psychology books, the two I have most enjoyed are written in non-technical language and can and should be read by workers in all branches of science. In *The Mind's Best Work*, D.N. Perkins summarizes his own research on creativity and by showing that the underlying mental processes are no different from those used in everyday life debunks the mystery of creation that Arthur Koestler and others of his ilk have tried so hard to foster. George Miller's *Language and Speech* presents a lively summary of all aspects of work on language. It has the rare defect of being too short and leaves the reader avid for more.

#### **Nevill Mott**

In James Clerk Maxwell: A Biography, Ivan Tolstoy declares that his subject should be ranked next to Newton and Einstein. He sets out to explain why to the non-scientific reader, who, he says, may well have never heard of Maxwell. Of course, Maxwell's greatest achievement was his equations for the electromagnetic field, and according to the author what was epoch-making in this was the replacement of Newton's action at a distance by the concept of an electromagnetic field.

On reading this book, I enjoyed being reminded of my first acquaintance with Maxwell's equations as an undergraduate, and my feeling that the concept of the displacement current was a supreme example of the power of mathematics to show that what is, must be. I can think of only one comparable example, Dirac's proof that an electron which obeys the laws of relativity and of quantum mechanics must have a fourth degree of freedom. Such things are at the very summit of theoretical physics, and I much enjoyed Professor Tolstoy's attempt to bring this great man's life before

#### **Lewis Thomas**

ON A complicated planet, meaninglessness keeps popping up as explanation: the world makes no sense; we are alone in jumpy randomness, getting nowhere. Amidst this confusion, 1981 provided us with three guide books.

In Laws of the Game, Manfred Eigen and Ruthild Winkler glimpse, at a distance, the world at play. Genetic rearrangement, generative grammar and Bach take the same chances, live by the same rules.

Donald Griffin's *The Question of Animal Awareness* is out to show that quick thinking, not all that different from what we think is thinking, abounds. A bee knows what bees are up to. Bats puzzle their way through the dark. Tiny brains can have tiny thoughts.

With high zest, in Symbiosis in Cell Evolution Lynn Margulis presents the case for cooperative living as a triumph of evolutionary fitness, an intricate but sure way up life's ladder, the best of games.

#### William T. Golden

Would'st thou hear what Man can say In a little? Reader, stay.\*

Statistical Abstract of the United States (101st Annual Edition) presents extensive information on the country's social, political and economic organization. Informative texts introduce the 34 sections (Agriculture, Education, Population, Science, for example); 1,616 tables, 71 charts in 1,059 pages. Something for everyone.

D'ye ken frog from toad, street from road, seer from prophet, amulet from talisman, wasp from hornet; and hundreds more? Then, for fun and edification consult Room's *Dictionary of Distinguishables*.

Leonardo da Vinci: the complex genius, peerless artist, technological visionary, military inventor and opportunist, stirs mind and soul in Martin Kemp's cogently written, generously illustrated analysis. Truly the marvellous works of nature and man.

\*Ben Jonson, Epitaph on Elizabeth L.H.

#### June Goodfield

STEPHEN Jay Gould's *The Mismeasure of Man* achieves several things, one of which is outstanding. By superlative historical scholarship and critical analysis, he demolishes those attempts to limit the lives of other human beings by "measuring" their intelligence whether by the dimensions of their skulls — as in the nineteenth century — or by testing their "supposed" IQs in the twentieth.

His achievement is, first, to demonstrate the strengths and limits of a quantitative measure in science; second, to show that even while science truly *cannot* ever be wholly detached and objective, for prejudices and unconscious attitudes do indeed influence what its practitioners see and interpret, the enterprise nonetheless *does* provide us with a marvellous method for challenging the *status quo*, as well as revealing firm knowledge about the world; third, he reaffirms how much is humanly possible.

#### J.Z. Young

RICHARD Leakey's *The Making of Mankind* provides an objective and also beautiful summary of the known evidence about human ancestry. He deals with the facts of the evolution of culture, language and even of civilization and cities, as well as of skulls. He concludes with some wise thoughts about the present, in which he rejects the views of Ardrey, Lorenz and others that human beings are unredeemably aggressive.

This book is a fitting sequel to Solly Zuckerman's classic, *The Social Life of Monkeys and Apes*. When first published, in 1932, it provided many new insights into primate and human reproduction. Now it has been re-issued with a further contribution from the author, who also includes some sensible thoughts about the future.

#### A. Hallam

THERE have recently been some exciting developments in palaeontology. For lay readers, especially biologists, who want a clear, non-technical but authoritative account of the study of fossils from an ecological, biogeographical and evolutionary point of view, written in a lively style, 1981 brought Chris Paul's *The Natural History of Fossils*.

For specialists, the textbook by J.R. Dodd and R.J. Stanton, *Paleoecology: Concepts and Applications*, is a sound, comprehensive and well-documented review of recent research — it may well become the standard reference work for some years to come.

#### L. Beverly Halstead

I was delighted to find in Michael Ruse's new book, Is Science Sexist?, a philosopher stoutly defending evolution. Neo-Darwinism is under attack from many directions. The anti-Darwinians seem to be recruiting new forces: including two kamikaze pilots proclaiming Evolution from Space directed by a cosmic intelligence from South Wales. At this most critical juncture, we find a new vigorous army, philosophical under Michael Ruse, sweeping across the landscape scattering all before it. I know exactly how Wellington must have felt at Waterloo when Field Marshal G.L. von Blücher and his Prussian troops came into view. The war is not yet over but the final outcome is now assured. Charles Darwin would have been pleased to know you Michael Ruse.

#### Isaac Asimov

THE book that pleased and edified me most in 1981 was *Science: Good, Bad and Bogus* by Martin Gardner.

The writing is not strictly that of 1981, for it is a collection of Gardner's essays on various forms of pseudo-science that date back over the past 20 years. Still, aside from the sheer enjoyment Gardner's clear, rational and occasionally sardonic style brings me, 1981 is a year in which his sane voice is enormously important.

Pseudo-science and non-science is on the rise in the United States and the self-named "moral majority" is bringing the force of obscurantist religion into the fight against freedom of thought. Men like Gardner must make their voices heard and in this book he does so most effectively.

#### P.B. Medawar

THREE books have struck me greatly during the year. First, C.P. Snow's enthralling *The Physicists*, with an all-star cast. Olympian figures are not necessarily the most interesting or instructive but Snow makes them so because he is big enough himself to see them to scale. Snow himself, shrewd, learned and magnanimous, comes out as well as anyone.

J.M. Tanner's A History of the Study of Human Growth is notable as a history of important ideas — seen in a context of intellectual and social history.

Finally, M.F.A. Woodruff's *The Interaction of Cancer and Host: Its Therapeutic Significance* is a *tour de force* with the breadth and depth of a multi-author volume, yet the work of a single first-rate mind

#### **Eugene Garfield**

I MET V.V. Nalimov, the well-known Soviet statistician and cybernetician, at the first Moscow Book Fair. We were brought together by our mutual, long-standing interest in scientometrics. After I read his manuscripts, I recommended that we should publish two of his books.

In the Labyrinths of Language: A Mathematician's Journey investigates the languages of biology, art, mathematics, statistics and philosophy. Nalimov proposes a taxonomy of languages, which describes the spectrum-continuum of language, from the "hardest" (mathematics) to the "softest" (art, Hindu metaphysics).

Nalimov ranges even more widely in Faces of Science. In these essays, each reflecting a different aspect of science, he demonstrates that science is a large, self-organized information system. How could I, as a linguistics-trained, essay-writing, information scientist, resist these fascinating ideas?

## Archaeoastronomical anomalies

Clive Ruggles

The First Stargazers: An Introduction to the Origins of Astronomy. By James Cornell. Pp.262. ISBN US 0-684-16799-9; ISBN UK 0-485-30004-4. (Charles Scribner's Sons/Athlone: 1981.) £7.95, \$15.95.

ARCHAEOASTRONOMY is a new and potentially exciting discipline. Its precise aims - broadly, investigation of the astronomical practices of ancient societies through various aspects of their material legacy - and limitations are not (yet) well defined; it includes on the one hand studies of Mesoamerican structures, where site evidence can be considered alongside written evidence from codices and ethnohistoric evidence, and on the other studies of British megalithic sites, where conclusions depend almost entirely upon the statistics of alignments and horizon indications. Almost all workers in the field are part-time, retired or amateur, and their main interests cover a variety of academic disciplines. The scientific value of much archaeoastronomical evidence has still to be properly determined; methodological improvements are only now generally being made. Thus the status of much potentially interesting field work has yet to be reassessed and confirmed.

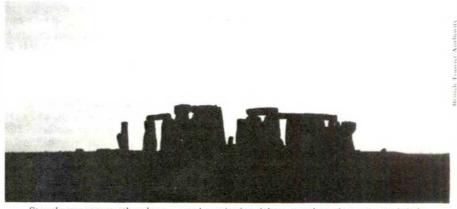

All of this presents the popular writer on archaeoastronomy with a number of problems. First, he has to cope with a confusing diversity of material, geographically and in terms of approach and quality. Second, he has to give some account of the difference between testable hypotheses and valueless speculation, and distinguish between different theories on these grounds. Finally, he has to combat the many popular misunderstandings, and be careful not to be drawn into endorsing purely speculative or now-refuted ideas on the grounds that they provide exciting material and help to sell books.

On the first count James Cornell has coped very well indeed; material is organized into chapters on a geographical basis, and general points are made whilst discussing particular sites or theories.

However on the second and third counts the book is a mixed bag, indeed: on occasions the author has done an excellent job, but on others he has failed dismally, and, worse, will badly mislead.

There are many instances in the book where valid theory is well separated from mere speculation, and the point is often made that deliberate astronomical orientations need to be distinguished from mere chance occurrences. In the opening descriptions of equinoctial sunset over a pyramid at Chichén-Itzá in Mexico, Cornell follows a description of a shadow phenomenon by asking "is this merely coincidence?" and explaining why he thinks it is not. Later he uses the example of a rock carving at Toro Muerto in Peru to illustrate a point about subjectivity and different possible interpretations. In the chapter on Egyptian temples, a reasonable approach (by Gerald Hawkins) is well distinguished from the speculations of various "pyramidologists". A good account is given of both sides of an argument about the astronomical interpretation of rock art. The "Sirius mystery" of the Dogon tribe in Africa, and its probable explanation in terms of earlier contact with someone from the outside world, is entertainingly recounted. And so on.

The author is not, however, always so clear about why he is ready to endorse some theories and dismiss others, and does not always identify the more speculative theories as such. Thus we hear that Alexander Marshack's ideas on lunar notation amongst bone scratches from the Cro-Magnon period are "steadily winning support throughout the scientific community". There is scarce mention of a more objective approach, which might ask how many other interpretations could equally well have been placed upon the bone marks. Instead, we are told how a "background as a journalist, screenwriter and popularizer of science does not help win support in the scientific community". The author might reflect that in some cases this might be due to an inadequate apprec-

Stonehenge sees another dawn — and continuing debate over how the stones and their alignments should be interpreted.

iation of the rigours of the scientific method.

Mr Cornell is at his most dogmatic in the chapter on Stonehenge, which is disappointing and, indeed, infuriating. Here we see regurgitated the Stonehenge debate of the 1960s, with Gerald Hawkins hailed as "having refuted nearly a century of archaeological dogma" and "having begun a revolution that would lead to a complete rethinking of the intellectual development of humankind", while archaeologists such as Richard Atkinson are denigrated for daring to criticize, and are said to be motivated by their "traditional view of these people as backward barbarians". In the same chapter Lockyer's earlier theories are discussed and justly criticized, but when it comes to Hawkins there is suddenly a flagrant disregard for any objective discussion. Instead, as one encounters more and more references throughout the book to Hawkins's "pioneering research at Stonehenge", how he has been praised as the "father of archaeoastronomy", and how he "almost single-handedly changed public and scientific conceptions of archaeoastronomy", one begins to wonder if this isn't really a Gerald Hawkins tribute

It is certainly true that Hawkins's work on Stonehenge led to a general public interest in archaeoastronomy and it is undeniable that Hawkins has done much work of value in this field, but the work on Stonehenge itself was soon criticized on justifiable grounds. It is perhaps worth (tiresome though it is to have to do so, for it has been done several times) briefly putting the record straight here. The astronomical interpretation of Stonehenge I rests on the finding that 24 out of 50 possible alignments between pairs of features at Stonehenge I were of astronomical significance. The chances of this happening fortuitously were calculated by Hawkins to be less than one in a million, as quoted by Cornell. In fact, there were 24 lines out of a total possible of over 100, since alignments both ways along most pairs were allowed as possibly astronomical; Hawkins calculated the probability of exactly 24 astronomical "hits" rather than 24 or more, and different tolerances were allowed on different lines. When these errors are taken into account, no evidence whatsoever remains for preferential astronomical orientation. This is quite apart from any archaeological and other arguments about the choice of features for inclusion in the analysis. These errors are simple ones certainly not a case for "mathematicians still arguing" as stated by Cornell - and, although they were pointed out by Atkinson only a year after the publication of Hawkins's Stonehenge Decoded (Doubleday, 1965), even now they are still present in current reprints of the book. This fact does not imply any great commitment to objective research, and it is tragic that Cornell's book, if widely read,

will only revitalize public misconceptions on this point. Cornell rightly points out that Hawkins's conclusions "never seemed to bother a technically attuned public": with the exception, one may surmise, of those with a questioning mind and some high-school mathematics.

In the chapter on Stonehenge and British archaeoastronomy in general, the author dismisses the archaeoastronomical work of Professor Alexander Thom in less than three pages, and mentions later that Thom's work scores a very low "reliability value" according to criteria devised by Hawkins (under which, not surprisingly, Hawkins's own work scores a high value). This sort of denigration is insidious. Thom has investigated a large number of sites, presented his results in a manner so that they can be readily re-examined and criticized and has been prepared to modify his opinions in the light of criticism and new evidence. (I am amongst those attempting critical assessments of his work.) In this manner, hypotheses are presented, criticized and modified, a procedure in accord with the scientific method but perhaps less susceptible to large-scale popular interest.

There are a number of minor errors in

the book which there is no room to mention in detail, particularly amongst the astronomical background material cunningly concealed amidst discussion of Toro Muerto and Marshack's work (that it is cunningly concealed is not a criticism).

But the overriding criticism of this book must be its one-sided and misleading treatment of British archaeoastronomy, in particular the almost fanatical praise of Hawkins and detriment of his critics. The complete break with objectivity in this respect must invalidate the value of the rest of the book, at least for non-specialist readers (and this is the intended audience) who cannot judge for themselves. Indeed, it will quite possibly have a worse effect, for in raking up past confusions and prejudices, amongst an objective discussion of other fields of archaeoastronomy, together with its several references to the prejudice of archaeologists against new ideas, it threatens to direct popular support towards sensationalism and away from level-headed scientific research.

Clive Ruggles is University of Wales Research Fellow in the Department of Archaeology at University College, Cardiff.

### **Exploring Britain's prehistoric past**

Ruth D. Whitehouse

The Penguin Guide to Prehistoric England and Wales. By James Dyer. Pp. 384. ISBN 0-7139-1149-6. (Allen Lane: 1981.) £9.50.

POPULAR interest in archaeology in the British Isles has never been higher, an interest which has brought increasing numbers of visitors to the visible remains of our past, our ancient monuments. James Dyer's book is a concise guide to almost a thousand of the most interesting sites of the prehistoric period in England and Wales. It is not the only guide of its kind: competitors include Nicholas Thomas's Guide to Prehistoric England (Batsford, 2nd Edn 1973), Richard Wainwright's A Guide to the Prehistoric Remains in Britain: South and East (Constable, 1978) and James Dyer's own Southern England: An Archaeological Guide (Faber, 1973).

The advantage of the new Penguin guide over these other works is its wider geographical coverage and the larger number of sites included. It begins with a section of five maps and a short introduction to British prehistory. The main part of the book consists of a gazetteer of sites, listed alphabetically by county. The gazetteer itself is excellent: the accounts of sites are concise and accurate, with Ordnance Survey grid references included; many of the site descriptions include one or more bibliographical

references and some are illustrated with photographs or line drawings. The visitor is therefore provided both with clear descriptions and an introduction to further reading.

Less satisfactory is the introduction. Archaeology today is developing fast and is characterized by controversy and debate on almost every topic. Dyer ignores this and presents a consensus view of British prehistory, which may accurately reflect majority opinion, but which neglects the new approaches and hypotheses that have transformed the subject in recent years. To take a single example, the Beaker pottery and associated artefacts of the third millennium BC are explained in terms of people migrating into and across England. This is indeed the traditional interpretation, but there is an alternative view that they represent a "status kit" of prestigious objects which were acquired by influential and wealthy people in different societies and were distributed not by migration, but by trade or exchange. While a guide book is not perhaps the proper forum for the airing of controversy, the onus surely remains to provide an up-to-date level of interpretation. Nonetheless, this is a book that everyone interested in Britain's prehistoric past will wish to own.

Ruth D. Whitehouse is a Lecturer in Prehistoric Archaeology at the University of Lancaster.

#### Odds and ends about the dead and buried

Stuart Piggott

Rites of the Gods. By Aubrey Burl. Pp. 258. ISBN 0-460-04313-7. (Dent: 1981.) £12.

WITH its meretricious title and dust-jacket, is Mr Burl's book going to lead us to take the "misdirected step" that "leads one towards apparitions, White Goddesses, psychic archaeology and the Never-Never land of the ley-liners"? Of course not: the deservedly caustic phrases are those of the author. But his book is not quite what it might seem to be, for it is not a discussion of ancient non-Christian cults, not even of those inferred for prehistoric Europe, but is limited in space to the British Isles and in time to a period c. 4500-1000 BC, with sketchy chapters for the phases before and after. Within these limitations Mr Burl presents to the non-archaeological reader some of the inferences which can be made as to ritual practice and performance from the material culture of burial and ceremonial monuments, a field to which he has made important contributions.

In the six chapters which form the bulk of the book the treatment is not thematic but topographical, with what seems a capriciously selected series of field monuments, some surviving, some destroyed or invisible from the ground. This does not make for easy or even very interesting reading, and obscures the real topics which could have been explored, such as the variations perceptible in the rites of collective burial - successive, redeposited, partial or complete - or a fuller treatment of the claims for astronomical expertise in British prehistory, on which the author has made pertinent comments elsewhere that deserve re-statement. Unfortunately, too, there are many errors of detail in the site descriptions, and the reports of early antiquarian diggings are sometimes given more credence in detail than they deserve. Modern "folklore" is also dealt with uncritically and without regard to the absorption by popular tradition, from the Renaissance onwards, of literate antiquarian speculations. Even less sure is the handling of anthropological evidence, where a sprinkling of words such as "shaman", "totem", "mana" or "sympathetic magic" hardly inspires confidence, and Ucko's classic paper of 1969 (World Archaeology I.2, 262-280) on precisely the problems posed by the interpretation of prehistoric funerary practice is not mentioned, though it should be required reading for all concerned. The limitations of inference from "grave archaeology" are nowhere set out.

Surprisingly, when in the later first millennium BC something, however tenuous, becomes explicit in Celtic religion, the book tails away. Here it is strange, in view of the prominence rightly given to henge monuments and allied structures earlier in the book, that nothing

is said of the evidence discussed in several recent papers for an insular survival of this pre-Celtic sanctuary tradition in such sites as Dun Ailinne or Emain Macha (and Tara), with probable British counterparts; the circular timber Iron Age temple beneath the Roman structure on Hayling Island is among other new and important cult sites of the period.

All in all, Rites of the Gods cannot be called a success, and does little more than present the reader with a scrap-book of miscellaneous data, too often interpreted in terms of modern modes of thinking. I had expected, and the general public deserves, something much better from Mr Burl

Stuart Piggott retired as Abercromby Professor of Archaeology at the University of Edinburgh in 1977. His books include Ancient Europe (Edinburgh University Press, 1965) and The Druids (Thames & Hudson/Pelican, 1974).

### Jupiter and the Moon displayed

David W. Hughes

I FIND map books fascinating and spend many happy hours investigating a specific country and tracing the lines of equal height, geological structure, nationality, temperature, rainfall, population, magnetic inclination and so on. The fascination seems to be a function of the amount of information displayed, so turning to the planets the first question is, "Do we know enough to fill a good atlas?". Looking at the two atlases under review one also must ask if all the relevant information has been included.

The first two volumes in The Mitchell Beazley Library of Astronomical Atlases for Amateur and Professional Observers deal with Jupiter and the Moon. Jupiter has been written by Garry Hunt and Patrick Moore, who divide their attention equally between the planet and its satellites. There is no doubt about there being enough knowledge to fill an atlas here. The images from Voyager 1 and 2 and Pioneer 10 and 11, apart from revealing three new satellites and a ring around the planet, have provided a host of superb pictures. This atlas reproduces many of these in colour. It not only provides maps of Jupiter and its satellites, but it also reviews our knowledge of such topics as The Great Red Spot, the interior of Jupiter, the magnetosphere, the effect of Io on Jovian radio emission, cloud morphology and colouring, volcanism on Io, surface fracturing on Europa, and cratering on Callisto and Ganymede.

The book is well written, physical and astronomical terms being clearly and correctly defined.

After the excitement of the Pioneer and Voyager fly-bys we are now scientifically becalmed and must return to "oldfashioned" visual and photographic observations from Earth. No Earth-based telescope can show anything like the amount of detail provided by space imaging, but Jupiter can be kept under observation for a large fraction of each year. It is thus well worth mentioning that the bible of Jupiter watchers - Bertrand M. Peek's The Planet Jupiter, The Observer's Handbook - has been reissued in a revised edition (Faber and Faber; £10, \$29.95). Needless to say, with 170 pages devoted to observations of the belts and zones of Jupiter and their temporal variation, this book is not for the faint hearted.

The second atlas, *The Moon* by Patrick Moore, reflects, to quote the author, "the endless enjoyment to be gained simply from looking at the Moon". Despite being visited by astronauts and a multitude of unmanned probes, the Moon has lost nothing of its romance. Again, the atlas contains about 16 pages of colour plates and a large collection of stereographic, orthographic and Mercator maps of lunar regions.

The mobile man in the Moon — James B. Irwin and the Lunar Roving Vehicle. The picture is taken from Joseph Jackson and John Baumert's *Pictorial Guide to the Planets*, 3rd Edn, just published by Harper & Row, price £9.50.

Moore provides a basic introduction to crater morphology, lunar chronology, mascons, transient lunar phenomena, regolith formation and the recent space exploration programmes. I would have liked to have seen one or two coloured geological maps (a typical example could have been the US Geological Survey map of the Copernicus quadrangle) and maybe a detailed contour map would have been fun (NASA's lunar topographic orthophotomap of the Apollo 15 Hadley region would do). Additional detail about surface temperature variation, transient atmospheres and the present meteorite influx rate would also not have been amiss.

We all have our favourite crater and I was surprised that mine, Giordano Bruno (which *might* have been formed as recently as July 18, 1178), doesn't even rate a mention. However Moore has produced an ideal book for the amateur observer, and anyone who ever fancies turning a telescope or a pair of binoculars onto the Moon will find this atlas an excellent starting point and guide.

Despite the grandiose title given to the series by Mitchell Beazley I think the two atlases, especially *The Moon*, fall well into the amateur division of the astronomy book league. I must say, though, that at £6.95 each (in the US \$14.95, Rand McNally) their value for money will be hard to beat.

David W. Hughes is a Lecturer in Physics and Astronomy at The University of Sheffield.

### Guidance for the observant amateur

Patrick Moore

A Complete Manual of Amateur Astronomy. By P. Clay Sherrod. Pp. 319. ISBN hbk 0-13-162115-7; ISBN pbk 0-13-162107-6. (Prentice-Hall: 1981.) Hbk \$24.95, £18.70; pbk \$10.95, £8.20. The Practical Astronomer. By Colin A. Ronan. Pp.153. ISBN UK 0-333-31245-7; ISBN US 0-02-604500-1. (Macmillan, London/Macmillan, New York: 1981.) £8.95, \$20.

ALTHOUGH no book can be really regarded as complete, Clay Sherrod's *Manual* is certainly exhaustive, and it contains much up-to-date information which cannot be found elsewhere in convenient form. The author is a well-known amateur astronomer, and his experience will be found to be very useful to others.

Topics covered range from telescope selection and maintenance to naked-eye work (meteor observation, for example); studies of the Moon and planets; photoelectric photometry, and all kinds of astronomical photography. The sections dealing with equipment are of special value. Many amateurs tend to believe that setting up a photoelectric photometer is too much of an undertaking; reading this book may cause a change of outlook. The author stresses, rightly so, that the modern amateur has to be much more specialized than his predecessor of half a century ago.

There are, unfortunately, some blemishes, and the weakest parts of the book are those dealing with the Moon and planets. In the lunar section, no mention is made of transient lunar phenomena, even though it is here that the amateur can carry out his most valuable work. In some ways the information given is out of date: for instance, it is no longer believed that lunar rills are "dried beds of water flow" - this idea was abandoned many years ago, and analyses of the lunar samples brought home by the Apollo astronauts and the Russian Luna probes have shown that there are no hydrated materials on the Moon. The map of Mars given on p.141 is, frankly, of no use, and the list of Martian features includes many canals and other markings which do not exist at all - so that the amateur will be hard pressed to locate them! The most surprising statement is that in Saturn's system, "the satellites Titan, Mimas and Hyperion are those that you should study most during transit events". Any observer using a modest telescope to watch a transit of Mimas or Hyperion would indeed have to have keen vision.

There are comparable mistakes in the stellar lists. On p.204, it is said that Antares varies from magnitude 0.9 to 1.8 — in fact its fluctuations are too slight to be detected without using a photometer or some such device; Alpha Cassiopeiae never rises to magnitude 1.4, and even its variability is questionable (Kukarkin's catalogue omits it); presumably n Aquilae should be

 $\eta$  Aquilae, R Geminorum should be U Geminorum, and so on. These errors are trivial in themselves, but in a book aimed at providing a guide for amateurs they can be highly misleading.

All in all, it seems that the proof-reading has been inadequate, and that the author is not fully conversant with some of the latest research. But the merits of the book far outweigh the defects, and there is nothing which cannot be put right in the next edition. When this has been done, the book may well become a standard work.

Colin Ronan's book, The Practical Astronomer, is much more elementary, and aimed at the younger reader. As well as providing a general introduction to astronomy, it contains many practical demonstrations and experiments; the text is clear and riveting, and the illustrations excellent. A book to be strongly recommended.

Patrick Moore is an author and astronomer. His recent books include The Moon, Jupiter (with Garry Hunt) and The Atlas of the Universe, all published by Mitchell Beazley.

#### Cosmic methadone

William H. Press

The Edge of Infinity: Naked Singularities and the Destruction of Spacetime. By Paul Davies. Pp.194. ISBN UK 0-460-04490-7; ISBN US 0-671-44063-2. (Dent/Simon & Schuster: 1981.) £7.95, \$14.50.

"BEYOND black holes to the end of the universe", trumpets the cover blurb. The author, with more modest affect, relates a conversation among colleagues bemused at the plethora of black-hole books: "'Whatever next?' someone asked. 'The naked singularity!' came a prompt reply. So I have written, with some amusement, a book about naked singularities".

A naked singularity, in modern relativity theory, is a region of spacetime where gravitational forces become infinite, crushing matter to infinite density, but from which light signals can escape, rendering the singularity visible. The singularity inside a black hole is not "naked" the choice of this word is usually attributed to Roger Penrose - but is, rather, modestly clothed behind an opaque "event horizon" (the surface of the black hole) through which outward light signals cannot propagate. The big-bang singularity from which our Universe expanded is, however, naked: the 3K cosmic microwave background is a signal from that singularity (or, at least, from as close to that event as the opacity of dense, ionized matter will allow us to look).

# **High Energy Astrophysics**An Informal Introduction for Students of Physics and

Astronomy

High energy astrophysics and astronomy are introduced in the course of the exposition of one specific problem, the origin of cosmic rays. Professor Longair discusses their detection, how they reach Earth, their sources, and introduces a wide range of diagnostic tools for the study of plasmas, developing all the necessary physics from Hard covers £24.00 net elementary physical principles. Paperback £8.95 net

# Microfossils from Recent and Fossil Shelf

edited by J.W. Neale, Professor of Micropalaeontology,

and M.D. Brasier, Lecturer in Geology, University of Hull

A valuable coverage of recent work, ideas and research on a wide variety of faunal groups ranging from the Silurian to the present day. The book is unique in its global scope, representing the state of the art in a well-balanced and timely overview of present-day thinking.

Zonal tables; numerous high quality illustrations; important data on correlation in the form of detailed investigations of distribution and the zonal tables are included. There is assessment of the factors which influence particular distributions in modern and fossil shelf sea areas, and studies which assess the fossil distribution and its significance in terms of the environment and setting.

# Lead in Man and the Environment

by J.M. Ratcliffe, Visiting Scientist, National Institute for Occupational Safety and Health, Cincinnati, Ohio

An integrated, up-to-date review of the health effects, environmental pathways and control strategies for lead, both in man and his environment.

The book offers discussion of the available literature, with extensive references and, unlike existing works, is a critical and totally independent review. It informs on government policy, legislative measures, and the toxicological bases for current biological standards. Here is a bringing-together of the various and topical problems of lead to illustrate the principles, the measurements and the evaluation of environmental hazards, the derivation of biological standards and the ways in which sources of lead intake and acceptable limits of exposure are integated into control strategies.

# **Biosynthesis of Natural Products**

by P. Manitto, Professor of Organic Chemistry, Faculty of Science, University of Milan

This comprehensive introduction to the intricacies of metabolism in plants and animals shows the means by which nature employs simple and complex organic compounds to generate the rich and powerful store of natural products.

The author surveys the field carefully and thoroughly, preceding each topic by an introductory section, followed by complete in-depth explanations, and a wealth of diagrams illustrative of the text. Research methods and techniques are probed, as well as isotopic tracer methods and the administration of labelled substrates.

In claiming to have given us a book "beyond black holes", the author is gently pulling our legs. Really, the book is another black-hole book — quite a fine specimen of the genre — and it is also about all those other popular buzzwords which have leaped from relativity theory into the public domain: warped spacetime, gravitational collapse, the big bang, Schwarzschild radius, Hawking radiation and so on

The market for these books seems as insatiable as that for Rubik's cubes. It is out of this crowded pack that Paul Davies has emerged as a prolific and, I think, major figure in popular science writing. This book is his sixth or so in less than five years. They keep getting better and better. Davies writes with a clear, sure, sane voice, at once understandable and astonishingly close to the Nirvana of total technical accuracy.

There are other good, popular blackhole books of course. One, Iain Nicolson's Gravity, Black Holes, and the Universe, was praised by Paul Davies recently in Nature (290, 656) in phrases even more applicable to Davies's own book: . . . maintains a reliable scientific perspective and a careful treatment, yet covers most of the 'fun' topics in detail". What sets Davies's book apart is not just that it is good, but that it is determinably good, written by an author with a nowestablished corpus of good science writing behind him and (one hopes) with more still to come. Librarians can confidently put him on their automatic-purchase lists.

Who are Davies's readers? One understands, to be sure, that there are two entirely distinct audiences for popular science, each blissfully ignorant of the other's existence. Group A, beloved by "serious" science popularizers, is imagined to consist entirely of educated country gentlemen and intelligent highschool students. Group B, the targets of science writers who want to make some money, are the gee-whizz junkies, uncritically addicted to the wildest and

Paul Davies — "a clear, sure, sane voice" for both country gentlemen and the gee-whizz junkies.

most irresponsible sorts of speculation. Astonishingly, I think that Paul Davies, in this book, will appeal to both groups. He is onto something that is either a great scam, or a great advance, in science popularization: the Group B addict is lured by a flashy pitch, promised the excitement that he so badly needs. What he gets instead is a

sane and accurate exposition, a detoxification instead of a "high". The Group A reader, meanwhile, not only finds the pitch amusing, but also the actual content entirely satisfactory.

William H. Press is Professor of Astronomy and of Physics at Harvard University.

# A new dimension to evolutionary theory?

D.A.J. Tyrrell

Evolution from Space. By Fred Hoyle and Chandra Wickramasinghe. Pp.176. ISBN 0-460-04535-0. (Dent: 1981.) £7.95.

THIS is in many ways an attractive book. The cover suggests the sky at night, but it is actually a photograph of "cell bodies in mollusc" culled from Nature — a clever visual linking of the ideas in the book. And the book is clever too; it ranges with relaxed ease over some biological oddities, such as the fact that Drosophila responds to UV light of wavelengths too short to be found on Earth, that Vicia faba, a member of the pea family, makes haemoglobin and that some bacteria are incredibly resistant to radiation. In style it seems intended for the general reader, and expounds a grand idea rather than presenting a closely argued case.

The idea is that biological evolution is widely regarded as proved and a complete explanation for the living world as we see it — yet there are awkward facts such as those I have just mentioned which to Hoyle and Wickramasinghe show that genes borne on particles in space have been incorporated into organisms on Earth. They also think this explains the sudden appearance of new species and the existence of gaps in the fossil record. They used essentially the same idea to "explain" in their earlier writings what they regarded as inexplicable features of infectious diseases; then the explanation was germs from space.

The authors make their own low estimates of the frequency of certain mutations and of the improbability that the amino acid sequence of any biologically significant protein could arise "by chance" in a primaeval soup. They then resolve the dilemma by mentioning Arrhenius' theory of "panspermia" and reformulating it by saying that "biomaterial" is parked on particles in space protected by low temperature and low gas concentration, and defended by graphite from radiation. They argue that the material on particles in a certain size range would remain viable after impinging on Earth, as described in their earlier books. In Chapter 7 this is likened to sprinkling new "computer programs" into computers in the planetary system and beyond - that is, new genes into species living throughout the Universe. They point out that studies which apparently showed

unexpectedly large numbers of bacteria in the upper air were discounted by NASA as due to contamination and were not followed up.

I think I understand the dilemma which made Hoyle and Wickramasinghe write the book. The intellectual difficulties of conceiving how life began and developed are stupendous, and the facile suggestions they sometimes include make one doubt the plausibility of some of the proposed schemes — in my own field I cannot see viruses as the "original" life since all those we know need energy and translation systems taken from whole cells in order to reproduce.

So, we agree that is difficult to explain how the first life forms were put together and why the fossil record suggests that either there were no links between certain species or evolution went very fast on a geological time scale. But this book merely moves these problems without solving them - for how were the genes in space created in the first place? And how, once landed on the Earth, were they incorporated into the genome of species already here? Genetic engineers can create environments in which genes can be implanted from without but the likelihood of this happening with extraterrestrial material in a natural environment is to me, intuitively, much less than that of evolution from time to time going so fast in so few animals that no fossil record has been found.

The authors are apparently sympathetic to the idea of a creative God, though most of the references are to one or more "intelligences", designated as ?, ?? and so on. I get the impression, for many important parts of their structure are not defined, that although they refer to the old theory of whole planets being disrupted and sending their germ plasm into orbit, the authors lean towards a concept of biomaterial being formed, perhaps de novo, in many parts of the Universe - a sort of biological continuous creation. But that again is moving the problem about in time, not solving it. I am afraid their hypothesis reminds me of the theological view labelled as "The God of the Gaps"; in fact they admit that their views are a form of the theory of special creation. Such theories bring in a God when the intellectual going gets tough and manage without between

times. It seems to me that it is very likely that the Universe is the creation of a God, but in that case I take the view that the whole grand structure, the bits I think I understand, as well as the bits I certainly don't, are and always have been manifestations of the same intelligence and creating and sustaining power.

On the same basis, although a Creator obviously could at any time or place suspend the "laws of nature" as we have observed them, we can use the method and approach of science only if we assume that these laws operate consistently in time and space. Here the argument echoes that of the "creationists" and "evolutionists" in the USA. It might happen that a scientific examination forced the conclusion that, apart from the existence of the Universe in time and space, some other specific creation events or insertions of genes from space could be demonstrated to have taken place. Hoyle and Wickramasinghe have not convinced me - though my mind is still open.

D.A.J. Tyrrell is Deputy Director of the MRC Clinical Research Centre, Harrow, Middlesex.

# To be an astronomer

Stephen P. Maran

In Quest of Telescopes. By Martin Cohen. Pp.131. ISBN 0-9333-4625-5. (Sky Publishing, Cambridge, Mass: 1981.) \$11.95.

MARTIN Cohen, an expert on T Tauri stars and cometary nebulae, and an English astronomer in the grand tradition of observation and discovery, has written his "astronomical autobiography". Unashamedly still an amateur at heart, Cohen is one of the diminishing breed of professional astronomers who actually enjoy the view through the eyepiece while they make the arcane measurements of the trade.

The book describes a life-long love of telescopes and star-gazing by way of vignettes drawn mostly from time spent at the major observatories of the American West. A photograph of the awed author, dwarfed by the 200-inch Hale reflector, is symbolic representation of the principal theme, a paean to the beauty both of the stars and of the great instruments with which we study them. Helicopter rides in the snow-bound White Mountains aside, his travels to pursue observational research at remote sites in North and South America are typical of those of many astronomers of the present generation who, as Cohen says, "have become jet-set commuters"

Although I began ten years before Cohen and on the opposite shore of the Atlantic, I see that we had many corresponding experiences. The young Martin cycled around town to his first small telescopes and astronomy club meetings; I rode the New York subway to do the same. He twice mistook an internal reflection for a new comet; I watched a student repeatedly "adjust focus" of a Kitt Peak telescope by tweaking what was in fact the counterweight balance adjustment. We both erected mid-sized telescopes in the mountains near Tucson, and apparently both of us found that large, lightweight aluminium mirrors don't work, regardless of what experts once wrote.

In Ouest of Telescopes aims to show high-school students and others what the astronomer's life is like. This is accomplished as much by the brief accounts of how major insights and discoveries were achieved as in the tales of events in Minnesota, Arizona, Chile, California and Hawaii. The book provides a fine description of what it is like to visit and work at a great national observatory. There also are many instructive anecdotes, interspersed with amusing tales fit for telling on cloudy nights while the wind whistles round the dome. Of these, the best is Cohen's recollection of the invasion of an infrared observatory by a horde of moths, who so filled the optical path of the telescope that it was possible to sense their temperature if not, temporarily, that of the stars. I also was glad to find descriptions of the as yet inexplicable problems that intrigue the author, such as the circumstance that large and small stars seemingly are born in separate nurseries. Perhaps a young reader will some day find the answer.

This Quest lacks an account of teaching, which is a major responsibility for so many astronomers. Note also that the young readers inspired by Cohen will find fewer opportunities to enjoy the observatory life than did he; an "observing run" now often means a trip to a prosaic NASA or ESA

The Space Telescope — new opportunities for astronomers.

satellite control room. Further, in the 1990s, the data from the major mountain-based telescopes will surely flow to central city terminals or even directly to the "observer's" home institution, and jet-setting will fall off accordingly. High above, however, a few lucky astronomers will be operating their telescopes aboard the Space Shuttle.

Stephen P. Maran, a Senior Staff Scientist in the Laboratory for Astronomy and Solar Physics at the Goddard Space Flight Center, is currently helping to build a spectrograph for the Space Telescope.

# The chemists' Earth

Peter J. Smith

The Earth: Its Birth & Growth. By Minoru Ozima. Pp.117. ISBN hbk 0-521-23500-6; ISBN pbk 0-521-28005-2. (Cambridge University Press: 1981.) Hbk £10.50, \$22.50; pbk £3.95, \$8.95.

HERE is a cautionary tale. In 1947 the research vessel *Atlantis* dredged some metamorphosed basalts from the mid-Atlantic ridge at 30°N. When these rocks later came to be dated by the potassiumargon method they were found to be about 48 million years old, far from the roughly zero age they should have had on the basis of the seafloor spreading hypothesis just becoming popular. At the time this little inconsistency was put down to "error" (possibly the presence of excess argon-40, a well known age-invalidating phenomenon) and then conveniently forgotten.

Or rather it was forgotten by almost everyone but Minoru Ozima, who in the late 1960s had another go at dating the offending samples, this time using the new argon-argon technique with its isochron consistency test. In this way the correct age of the basalt was found to be 170 million years, thus producing even greater consternation involving accusations of specimen mishandling and cries of triumph from the "anti-spreaders". Observation and hypothesis were neatly reconciled in the end, however, by concluding that the basalt must have been left behind at the ridge from the time of the initial split of South America and Africa.

Only a geochemist would have the gall to embarrass the geophysical gods by dragging up this sort of thing; but the simple moral of the anecdote is well taken, namely, that isotope geochemistry has a vital role to play in elucidating the details of plate tectonic processes. What is more, unlike plate tectonic studies, which have hitherto concentrated largely on the past 200 million years, geochemical investigations are crucial in interpreting the whole course of the Earth's evolution. Earth scientists know this already, of course; but for the less specialist reader the more sober geochemical story has tended to fade against the background of the past two decades' blaze of geophysical publicity.

Ozima has set out to correct this unjust imbalance by providing for the general reader a short account of the way in which natural isotope studies have been used to trace the Earth's broad development. Beginning with the "birth of elements" in the nucleosynthesis that preceded the formation of the Solar System, he then looks in turn at the accretion of the Earth as a whole, the formation of the core, the separation of crust and mantle, subsequent changes in the crust, and the origin of the oceans and the atmosphere. The book ends with a discussion of the ways in which man-

# Scientific Side

# Forest Succession Concepts and Application

Editors: D.C. West, H.H. Shugart, D.B. Botkin With contributions by numerous experts

1981. 112 figures. XV, 517 pages (Springer Advanced Texts in Life Sciences) Cloth DM 87,-; approx. US \$ 40.50 ISBN 3-540-90597-9

Summarizing research in the field, this book includes coverage of:

- new and classical schools of thought
- new empirical observations
- simulation and analytical techniques over short- and long-range time scales.

Forest Succession is an up-to-date appraisal of the theory and practical aspects of forest succession in a wide variety of ecosystems.

# Resource Use by Chaparral and Matorral

A Comparison of Vegetation Function in Two Mediterranean Type Ecosystems

Editor: P.C.Miller

1981. 118 figures. XVIII, 455 pages (Ecological Studies, Volume 39) Cloth DM 98, -; approx. US \$ 45.70 ISBN 3-540-90556-1

Through the use of innovative simulation models the authors were able to quantitatively link the patterns of availability of resources with such processes as transpiration, photosynthesis, and nutrient uptake. The result is an evaluation of some commonly held generalities of ecological theory as well as a contribution to community theory.

# Forest Island Dynamics in Man-Dominated Landscapes

Editors: R.L.Burgess, D.M.Sharpe With contributions by numerous experts

1981. 61 figures. XVIII, 310 pages (Ecological Studies, Volume 41) Cloth DM 73,-; appro. US \$ 34.00 ISBN 3-540-90584-7

This book examines the ecology of forest fragments, or "islands", located in highly developed, deforested areas used for agriculture or urban needs. Analyses of entire regions as well as specific ecological and taxonomic groups are presented; theories of island biogeography are tested and applied; and models dealing with seed disposal, succession, local species extinction, and land use optimization are utilized.

F.H. Bormann, G.E. Likens

# Pattern and Process in a Forested Ecosystem

Disturbance, Development and the Steady State Based on the Hubbard Brook Ecosystem Study

2nd corrected printing. 1981. XI, 253 pages Cloth DM 48,-; approx. US \$ 22.40 ISBN 3-540-90321-6

"... The authors' command of diverse subject areas is impressive... As a clear synthesis of the Hubbard Brook studies and in terms of meeting its major objectives, the book is a success. The concepts and results presented therein are sure to stimulate further thinking, debate, and research in years to come..."

made, high-level radioactive wastes might be disposed of in the Earth — a nice irony considering that the sites under consideration have been shaped almost entirely by the heat from radioactive isotopes, albeit different ones.

To a great extent, isotope geochemistry is a matter of dating events and processes that have self-evidently taken place or have been shown to do so using other types of evidence. This has tended to give the topic a "service industry" image, which is perhaps another reason why would-be popularizers have concluded that it lacks glamour.

Ozima's considerable achievement in this book has been to demonstrate to laypeople and students the vitality, excitement and importance of isotope geochemistry as a subject in its own right. In this cause he has been helped beyond measure by Judy Wakabayashi, who has produced a beautiful translation that puts the majority of native scientific English writers to shame.

Peter J. Smith is Reader in the Department of Earth Sciences at the Open University, Milton Keynes, and editor of Open Earth.

# Ultimate histories and final destinations

John Noble Wilford

Cosmic Dawn: The Origins of Matter and Life. By Eric Chaisson. Pp.302. ISBN 0-316-13590-9. (Atlantic Monthly Press/Little, Brown, Toronto: 1981.) \$14.95. Genesis: The Origins of Man and the Universe. By John Gribbin. Pp.360. ISBN UK 0-460-04505-9; ISBN US 0-440-2832-9. (Dent/Delacorte: 1981.) £7.95, \$13.95.

In content, purpose and intended audience (the educated layperson), these two books are much alike. Both cover the same ground, which is to say that they start with the big bang and bring us forward through the creation of the Solar System to the emergence of life and the ascent of man. But they differ considerably in style. Cosmic Dawn is an extended essay, instructive and literate, building toward a moving statement on the human condition and prospects. Genesis is a comprehensive exposition of current consensus and debate on our origins, tutorial in style but lively and often provocative.

Chaisson, an associate professor of astrophysics at Harvard, has produced a work of history as much as of science, with its narrative force and synthesis of grand themes. Astrophysicists, as he says, are the "ultimate historians". His essay is shaped around two "critically important transformations in the history of the universe". The first was the emergence of matter from radiation; the second, the emergence of technologically intelligent life.

The latter, he writes,

is the quintessential event in the development of matter, the threshold beyond which life forms can truly begin to fathom their role in the cosmos. Significantly, then, we have an obligation, a responsibility to survive.

Michael Ruse's *The Darwinian Revolution* (reviewed in *Nature* **284**, 670; 1980) has been published in paperback by Chicago University Press, price \$9.95 (US only).

To survive as a civilization Chaisson contends that we must circumvent the very real possibilities of overpopulation, selfdestruction, genetic degeneration and subjugation by computers. Long-term survival of the species, he states in an eloquent conclusion, may depend on our commitment to a two-fold programme of simultaneously colonizing the nearby planets, which he sees as a dispersal of the species so as to be less vulnerable to local catastrophe, and searching for galactic civilizations, which, if found, might reassure us that others have attained technological power and still avoided doomsday. The case for extraterrestrial exploration has rarely been better stated.

Gribbin, an astrophysicist and prolific science writer, also concludes with a forward-looking chapter, "Destinations", and suggests, among other things, the possibility of our descendants developing a "space culture". But, in general, his discussion of the future is unfocused and unsatisfying. This is a pity, for the rest of the book is so clear and rich in detail and insight. Much more than Chaisson, Gribbin spells out the discoveries and reasoning behind current thinking in cosmology and biological evolution. His discussions of plate tectonics, the origins of diversity and the origins of Earth are especially lucid. His style, like a gifted lecturer's, is by turns playful and authoritative. The index and organization by subheadings make it easy to refer back to subjects of particular interest.

Either book can be recommended to the student who seeks a broad understanding of the origins of mankind and the Universe (students of the humanities might prefer Cosmic Dawn), or to the general reader who wants a rewarding experience delving into the "ultimate" history.

John Noble Wilford is a science correspondent of The New York Times who specializes in space exploration. His most recent book is The Mapmakers (Knopf, 1981).

# Pressure to scale

W.D. Hackmann

Barometers. By Bert Bolle. Pp.256. ISBN 0-85242-710-7. (Argus, Watford, Herts: 1981.) £12.50. Early Scientific Instruments. By Nigel Hawkes. Pp.168. ISBN 0-89659-192-1. (Abbeville Press, New York: 1981.) \$29.95.

COLLECTORS of antiques are becoming increasingly interested in scientific instruments. Sundials, telescopes, microscopes and barometers are amongst the most popular. Barometers, especially, have commanded wide interest because of their attractiveness as pieces of furniture. Bert Bolle, a Dutch antique-dealer, has been a barometer enthusiast for many years. His book, which was first published in The Netherlands in 1978, occupies a niche between the purely technical histories, such as that written by W.E.K. Middleton in his The History of the Barometer (Johns Hopkins Press, 1968), and those describing antique barometers, of which the best English example is N. Goodison's English Barometers 1680-1860 (Cassell, 1977).

The book is divided into three parts. The first describes the evolution of the various barometer types, and each chapter deals with a specific pattern: stick, marine, miner's or pit, sign-post, banjo and aneroid. Ancillary instruments, such as thermometers, hygrometers and psychrometers, are also discussed briefly. Between 70 and 80 thermometer scales were in existence in the eighteenth century, and a Dutch example of 1754 with 18 scales is illustrated.

The earliest barometers were simple tubes containing mercury, based on Torricelli's well-known experiment of 1644, to which Descartes added a scale four years later. At first, the arrangement was used to demonstrate the "weight of air" but there was a slow realization that it could be used in forecasting weather. Research shifted to England. Both Robert Boyle and Robert Hooke improved the design, and gradually during the 1680s instrument-makers, clock-makers and opticians started to manufacture barometers for domestic use. Within a short period the main mercury barometer types were established. Trade concentrated in Britain, and to a lesser extent in The Netherlands, where a double or contra tube system (the contra-"bakbarometer") was invented by Huygens. Amongst the earliest makers were the famous clock-makers Thomas Tompion and Daniel Quare, then, during the eighteenth century, the manufacture of barometers became the speciality of expatriate Italian craftsmen; two of the best-known Victorian firms, Negretti & Zambra and Pastorelli & Rapkin, evolved in this way. In The Netherlands, too, Italian makers appeared in the 1750s.

The second part of the book is an illustrated catalogue of about 135 barometers. As expected, most examples are British, but France, Germany, The Netherlands, Denmark and Austria are also represented. Finally the author deals with the barometers and ancillary instruments encountered in the preceding parts from a technical point of view. Useful tables converting old into present-day units are given, and also recipes, for example for the camphor solution used in storm glasses. A novel arrangement of the book is that in each of the three parts the same chapter numbering is used when describing the same class of barometer. For instance, Chapter 3 in all three sections refers to the stick barometer. This facilitates crossreferencing, but also causes some duplication.

Michael Holford's beautiful photographs give the second book its obvious appeal. Nigel Hawkes, the science correspondent of *The Observer*, has been eclectic in his selection, ranging from a sixteenthcentury astrolabe to a late nineteenthcentury mahogany and brass telephone switchboard. The instruments can be seen in three London institutions: the Science Museum, the National Maritime Museum at Greenwich and the Royal Institution.

A remarkable feature of the book is the extraordinary size of the lettering, usually associated with books specially printed for the elderly suffering from myopia. No doubt this was necessary so that the somewhat bare text could fill the large page size required for the plates. The descriptions given are reasonably accurate, indeed in a few instances more correct than the museum labels exhibited with the original instruments; but this is above all a picture book, which gives only haphazard glimpses into a fascinating history.

W.D. Hackmann is Assistant Curator of the Museum of the History of Science, University of Oxford.

# History through the looking glasses

Silvio A. Bedini

Collecting Microscopes. By Gerard L'E. Turner. Pp.120. ISBN UK 0-289-70882-6; ISBN US 0-8317-5950-X. (Studio Vista, London/Mayflower, New York: 1981.) £2.95, \$14.95. The Camera Obscura: A Chronicle. By John H. Hammond. Pp.182. ISBN 0-85274-451-X. (Adam Hilger, Bristol/Heyden, Philadelphia: 1981.) £13.50, \$33.50.

As Gerard Turner states in his introduction to *Collecting Microscopes*, "A book for collectors of microscopes must be both a history book and a guide book". It must not only describe the instrument's development, but also identify the leading makers and the capacity of the instrument in its various forms to perform its scientific tasks. This is indeed a large order for a volume of modest size, but the author manages to meet his own requirements extremely well.

The microscope has had a long and complex history in evolving from the simple instrument of the early seventeenth century to the modern electron microscope. It was an endeavour in which many countries took part and to which its users — anatomists and other men of science — made as substantial contributions as did the makers of the instruments. It is not surprising that in time the microscope became the universally recognized symbol of science because it had such a wide range of application, from medicine to geology and from botany to metallurgy.

The book ranges from descriptions of the optical structure of the microscope, the anatomy and materials, to individual chapters on the several basic structural forms. Special attention is given to the English and Continental microscopes produced in the nineteenth century, the period which saw its greatest development. Noteworthy are sections on special hints to collectors, names and addresses of the most important museum collections throughout the world, a guide to prices based on auction and other recent sales, and a comprehensive bibliography. The work is illustrated by splendid pictures, many in colour, and by numerous diagrams.

The author is recognized as one of the world's foremost authorities on the history of the microscope, and is the author of many writings on the subject. His early training as a research physicist and his museum experience contribute greatly to this attractive, authoritative volume, which no collector of microscopes, historian of science or museum curator can afford to overlook.

Hammond's history of the camera obscura is also a welcome addition to the literature of optical instruments; again, it will serve not only the collector but the historian as well. In this informative volume, Hammond traces the history of the instrument from its use by fifth-century Chinese philosophers through Greece to Europe, where it was known by the thirteenth century.

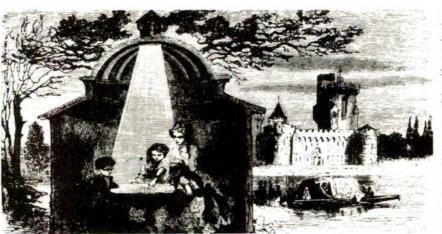

Simply stated, a camera obscura is a darkened room or an enclosed box into which light passes, generally through a lens, to form an image of external objects on the opposite surface. Gemma Frisius, Nicolas Copernicus, Tycho Brahe, Moestlin, Johannes Fabricius and Johann Kepler were early users of the instrument for observing eclipses, sun spots and planetary movements. The first portable model appears to have been designed by Robert Boyle and it was immediately imitated by others. Kepler devised a portable form in a tent which he probably used for his survey of upper Austria as well as for observing astronomical pheno-

The camera obscura progressed from serious scientific — and artistic — use to a device for public entertainment by magicians and other performers, and eventually was reduced to a parlour diversion. It was the subject of an extensive literature during the period of its maximum popularity, but more recently it has merited little more than passing mention in histories of science, art and photography.

In addition to a lucidly written, wellillustrated history, Hammond provides appendices and lists of references at the end of each chapter, as well as a comprehensive bibliography and full index.

Both of these authors have succeeded admirably in their aims; their books are contributions to the scientific literature as well as most useful and attractive guides for the collector.

Silvio A. Bedini is Keeper of Rare Books at the Smithsonian Institution, Washington DC, and specializes in the history of scientific instrumentation and horology.

The camera obscura as a diversion for children. The picture comes from F. Marion's Wonders of Optics (1868).

# Entry to the history and philosophy of science and medicine

Donald Cardwell

Dictionary of the History of Science. Edited by W.F. Bynum, E.J. Browne and Roy Porter. Pp.496. ISBN UK 0-333-29316-9; ISBN US 0-691-08287-1. (Macmillan Reference Books, London/Princeton University Press: 1981.) £17.50, \$40.

THE lexicographer is, according to a high authority, a drudge. But this description hardly fits the three editors of the Dictionary of the History of Science. All are active scholars in the history of medicine and they have had the assistance of no fewer than ten subject editors. The title of their dictionary, however, requires amplification. What we are given is, in fact, an encyclopaedia of the history and philosophy of science, comprising short articles on general topics of between 50 and 2,000 words, interspersed between about three times as many brief references to specific points in the short articles which, in effect, constitute an index. The form of the work is, then, a cross between an encyclopaedia and a dictionary with the emphasis on the former. Few archaic or obsolete words are included; alembic. athanor, pelican and that legion of prescientific chemical terms are absent.

In short, this dictionary is more didactic than narrowly informative and it reflects a very definite view of the history of science. Technology is confined to one article while the philosophy of science and the history of medicine are well represented. This policy must have entailed problems for the editors barometer, cloud-chamber, galvanometer, thermometer all qualify for inclusion, while ammeter, voltmeter, bridge (electrical) do not. Presumably the latter were considered technological and therefore outside the scope of the Dictionary. Clearly, there is a need for a companion volume on the history of technology.

A perusal of the brief references is not without its lighter moments. Anyone who is not a demographer must be intrigued by the reference: "average man. See statistics (vital)". On the other hand, "improper egg. See generation" calls to mind an entry in that incomparable index to Wyndham Lewis and Charles Lee's anthology, The Stuffed Owl, "Eggs, mention of, wrapped in elegant obscurity, 62". The reference, "women. See chlorosis; hygiene; malefemale differences" will annoy militant feminists as well as invite comparison with another entry in the aforementioned index, "Woman, useful as a protection against lions, 118". As for "museums. See fossils", this suggests a particularly sour opinion of museum curators.

On a more serious note, however, I must take issue with the editors on a number of points. Some of these are minor and amount to little more than expressions of opinion. Surely, for example,

Newtonianism merits more than 13 lines? And should not mention of Gibbs and Heaviside be included in any account, however short, of the history of vectors? The British Association is, very properly, included but not the older Deutsches Naturforschers Versammlung (1822). Again, hospitals find a place but there is, unaccountably, no room for laboratories. And for their part, Mancunians must regret that no reference is made to daltonism.

Most serious, in my view, is the failure to mention units and dimensions. The development of the theory of dimensions and the establishment of rational units were, taken together, a most important feature of the growth of physics in the past 200 years. The British Association Committee on electrical units (1861) may have been a response to the needs of telegraph engineers and the results of its labour may have been vital for the establishment of the world's electrical supply industry, but they were hardly less significant in the realm of "pure" science, in the formulation of electromagnetic field theory. After all, Maxwell was a member of the Committee and his seminal paper was published in 1865.

On the other hand, when we consider the articles that are included we are amply compensated. Apart from a few brief passages about contemporary and fashionable theories of science, that may well prove ephemeral, the short essays that form the bulk of the Dictionary cover an enormous variety of subjects, ancient and modern. These range from Ptolemaic astronomy and Islamic science to matrix mechanics and causality in quantum physics, from Aristotle's cosmology to the paradox of confirmation, from Naturphilosophie to molecular biology and the genetic code. The Dictionary, in other words, provides material for a comprehensive course on the history and philosophy of science.

The omissions can easily be attended to in future editions and, all things considered, this is a valuable work. It is well produced and the individual articles, by nearly 100 scholars, are authoritatively, carefully and clearly written. Every library and every scientific establishment should have a copy.

Donald S.L. Cardwell is Professor in and Head of the Department of History of Science and Technology at UMIST, Manchester.

# Plants in print: more of Thornton's Flora

S.M. Walters

The Temple of Flora. Introduction by Ronald King. Pp.112. ISBN UK 0-297-77984-2; ISBN US 0-8212-1128-5. (Weidenfeld & Nicolson, London/New York Graphic Society, Boston: 1981.) £18.50, \$35.

THE spate of handsomely produced botanical and horticultural books continues unabated, in spite of the recession, and even professionals find it difficult to pick their way through them. A new edition of Robert Thornton's Temple of Flora, containing a complete set of reproductions of the famous colour engravings, is, however, a publishing event overshadowing most of the rest especially at such a remarkably modest price. In a detailed introductory section, Ronald King, a former Secretary of the Royal Botanic Gardens at Kew, tells the story of this extraordinarily grandiose venture by Thornton, who dissipated a private fortune on his scheme in the first years of the nineteenth century. King's introduction goes further back than the reader might expect, beginning with the birth of Linnaeus, and tracing the rise of Linnaean botany in the second half of the eighteenth century and its relation to botany and horticulture as relaxations and

hobbies enjoyed by Queen and humble citizen alike.

Thornton received an important part of his education in Cambridge, where he obtained his medical degree in 1793, and came under the influence of Thomas Martyn, Professor of Botany, a great supporter of the new Linnaean systematics. His career in medicine seems to have been both unorthodox and relatively unsuccessful. The evidence is that he had conceived something of his grand plan for a magnificent book on Linnaean botany as early as 1791, whilst still at Cambridge in fact, although it was six years before his circumstances enabled him to launch the project. The inglorious failure of the whole scheme in the "Royal Botanic Lottery" of May 1813 is described in detail; it is a quite extraordinary story, from which Thornton emerges as a figure to be pitied or despised according to taste. He was never to know that the third volume of his great work would achieve permanent and international fame - a "lasting heirloom for the British nation", as King says.

The generous layout of this book involves some repetition, particularly between the text accompanying each plate and the relevant page in the Introduction, and the reader should be warned that

important information about the plates may only be found in the introductory reference. As an example, the botanical identification of the plates, a technical and specialist matter, is not systematically included in the legends, although it can (in all cases?) be gleaned somewhere in the Introduction, Proof-reading seems to have been very good, though a small error occurs on p.16 in the title of Sir John Hill's Flora, which is given as Flora Botanica — a particularly odd mistake, since Sir John himself had mis-spelt his own title by calling the work Flora Britanica.

An adequate bibliography provides access to all relevant works including the most recent (1972) edition of the Temple of Flora, published by Collins and now out of print. Purchasers of this new edition may find it interesting and instructive to consult the Collins book in a library; in it Geoffrey Grigson gives a more concise account of Thornton's work which is also less tolerant of his vanity, greed for success, taste for bad poetry and generally (to us) his excessively "purple" prose style than is that given by King. Yet both agree, as the whole botanical world does, that the plates are superb. The publishers are to be congratulated on making them available again.

S.M. Walters is Director of the University Botanic Garden, Cambridge, and author of The Shaping of Cambridge Botany (Cambridge University Press, 1981).

# The flowering of botanical illustration . . .

Sandra Raphael

The Art of the Botanist. (In the USA The Art of the Plant World.) By Martyn Rix. Pp.224. ISBN UK 0-7188-2482-2; ISBN US 0-87951-118-4. (Lutterworth, London/ Overlook Press, New York: 1981.) £25, \$60 until 31 December, £30, \$75 thereafter. Curtis's Flower Garden Displayed. Descriptions by Tyler Whittle and Christopher Cook. Pp.258. ISBN 0-19-217715-X. (Oxford University Press: 1981.) £19.50,

THE best botanical illustrations, most obviously the greatest eighteenth-century ones, transcend their strictly utilitarian purpose of recording the appearance of plants and become works of art in their own right. Dr Rix's book is called The Art of the Botanist, and its large format seems to give priority to the pictures; but the text that accompanies them is more like a frustrated account of botanical exploration than, as is intended, a history of botanical illustration. In an ideal world, this subject would be treated by an author equally at home with botany, bibliography and art history. Dr Rix is primarily a botanist, and the book reflects this lack of balance, for he is obviously more comfortable once he reaches the eighteenth century and the start of modern botany.

The first quarter of the book skims over the earliest manuscript and printed herbals and plant pictures, ending with a chapter on exploration in the sixteenth and seventeenth centuries and the books that hold the records of the new plants of the period. The next, and longest, part of the book deals mainly with the eighteenth century, perhaps the greatest age of botanical illustration, with a geographical arrangement leading to a tangled treatment of chronological developments. The final section starts as lithography begins to take over from engraving and covers nineteenth-century publications and the merest handful of twentieth-century work.

The pictures are, of course, the book's raison d'être - 250 of them in black and white and 64 in colour, all in only 220 large pages. They are beautiful, and the photographic quality is generally good; but the book's design does not give them the setting they deserve. The pages are packed, but the demands of colour-printing mean that pictures are often some distance away from the relevant text. No indication of the size of the originals accompanies the reproductions, so that those unacquainted with the books concerned are given no idea of their scale. Black frames surround nearly all of the pictures, a real distraction when several are printed on one large page, when the effect produced is that of a sheet of large stamps. The colour plates on pages 160 and 161 make a really unhappy pair, the strelitzia from Redouté's Les Liliacées at its best a clownish plant and hardly a beauty - facing the night-blooming cereus, complete with romantic background, "moonlight by Pether' from Thornton's Temple of Flora. Both of these would look infinitely better with more compatible neighbours.

An advertisement for The Art of the Botanist has described it as a definitive history of its subject. Even if one makes allowances for the context of such a statement, it is one to be treated with great caution. The book's bibliography is absurdly inadequate. Many important sources of relevant information appear to have been ignored, not least the Calmann study of G.D. Ehret, published in 1977 and the standard work on one of the greatest of flower painters. Dr Rix says a good deal about the Duchess of Portland's collection of Ehrets, although he is apparently unaware that two volumes of them have recently been identified in Oxford. He also mentions the Windsor copy of an Aztec herbal of 1552, "in which only one or two of the plants are actually recognisable", without troubling to tell us that the Windsor herbal is apparently a copy of the Badianus manuscript in the Vatican Library, published in facsimile in 1940 by E.W. Emmart, who also provided copious notes in which several of the plants are identified. The Plantin collection of plant illustrations, the source of so many of the pictures in sixteenth- and seventeenthcentury herbals, is given a few lines, but the recent rediscovery of it in Cracow, after its removal from Berlin during the last war, goes unnoticed. So one could go on. In addition there is the usual crop of minor misprints, among others, that hardy annual that turns the Pierpont Morgan Library into the Pierpoint Morgan.

Dr Rix's own travels have taken him to some of the regions explored by earlier botanists, and his book is most vivid when he can add his own first-hand comments to theirs. A member of Tournefort's expedition discovered a large vetch, apparently encountered by Dr Rix too, for he tells us that its "succulent young shoots" are "still much eaten by shepherd boys"

A picture book then, but not a definitive history of botanical illustration. For the nearest approach to such a thing we must still rely on Wilfrid Blunt's The Art of Botanical Illustration (1950) - much quoted by Dr Rix — and Claus Nissen's Die Botanische Buchillustration (1966)

Curtis's Flower Garden Displayed includes 120 plates chosen from about a thousand printed in Curtis's Botanical Magazine during its first 20 years (1787-1807) and 25 volumes. periodical, now not far short of its bicentenary, was founded to describe garden and greenhouse plants, each plate being accompanied by a short note giving a description, a potted history and notes on cultivation. The plants selected by Tyler Whittle and Christopher Cook have been arranged in order of their introduction to Europe, with the original text replaced by a new one, mixing botany, gardening and historical chit-chat with quotations from Turner, Gerard, Parkinson, Curtis himself and other botanical classics.

In Lib. primum Dioscoridis. 215

illium ex aqua,ah inflummatione uindicat lingur afpernates eum melle abfletgit : candida fixminanum profuosia filit hamorthoidas fanat, cum querno carbone intrito admotum. Aqua,in qua femen madut, decocha cogitua, conque, efficacior quodammodo ipfo femine. Gumini defert , quod demiuma caus innorimmina ad dolores himendos.

Her Grantson, will firstle Plantschlik (2011) agust.) Lather me et indian norme, Ismach stjene sulgimetary accele somerond store and experience corporate soll of spin spin terms in the first life. Her is understand pri felt staketare antique interna Englande up spin copitations, that the two-que which a sprayer. Consequent and the spin accelerate and devotines have when the proposes, when a parameter delector. Neglister on the

"Rhus", possibly the stag's horn sumach (Rhus typhina). Woodcut from Commentarii in Sex Libros Pedacii Dioscoridis, 1565 edition, by Pierandrea Matthioli.

The arrangement echoes that of the Botanical Magazine itself, each plate facing its appropriate text. The plates are good copies of the originals, and the book is a very attractive production, making it even more of a pity that such a pleasant piece of printing is spoiled by extremely careless copy-editing and proof-reading. Misprints are numerous, perhaps the most comic being "naval wort" for navel-wort. Several personal names appear in variant forms; even Linnaeus's are given in the wrong order: Linnaeus was his family name, and he did not become von Linné until he was ennobled.

This selection of early Curtis plates will be welcomed by gardeners interested in the history of the plants they grow. It might even lead them to a full set of the *Botanical Magazine* itself, or perhaps to the dozen plates from recent issues sold as a calendar at Kew each year — a pleasant annual glimpse of some of the best of today's botanical illustration.

Sandra Raphael is Senior Editor (Natural History) in the Dictionary Department of Oxford University Press. She is currently working on a new edition of Wilfrid Blunt's The Art of Botanical Illustration.

# . . . and of the garden at Cambridge

Blanche Henrey

The Shaping of Cambridge Botany: A Short History of Whole-Plant Botany in Cambridge from the Time of Ray into the Present Century. By S.M. Walters. Pp.121. ISBN 0-521-23795-5. (Cambridge University Press: 1981.) £17.50, \$42.50.

This slim quarto volume was published to mark the 150th anniversary of an Act of Parliament, dated 30 March 1831, authorizing the acquisition of land from Trinity Hall for the development of a New Botanic Garden. By that time the eighteenth-century Walkerian Garden founded in 1762 had become too small, and, in the words of the Professor of Botany, J.S. Henslow, "utterly unsuited to the demands of modern science".

The book gives a brief and interesting history of the scientific study of botany in Cambridge; and the author, though not going very deeply into his subject, provides the botanist with a useful and handy source book. Moreover, at the present time when the study of garden history has such a wide appeal, a publication with special reference to the teaching, planning and research, carried on over the years in the garden at Cambridge, offers much of interest to the garden historian.

Dr Walters, at one time Curator of the Cambridge Herbarium and Lecturer in the Botany School, and now Director of the Garden, has written this book chiefly from material obtained from published works, from some unpublished manuscripts and from knowledge that he has acquired over many years of association with the University. It consists of a history of botanical and horticultural science in Cambridge from the seventeenth century, when John Ray established the tradition of herborizing, or plant hunting expeditions. until the establishment of specialized modern branches of botany, such as genetics and ecology, in the present century.

The eight chapters cover various stages in the development of the Garden and Cambridge botany. Details are given of the lives of the important figures in the history of the science and the part that some of these men played. Among them, from the time of Ray until 1825, are Richard Bradley, and John and Thomas Martyn, and from 1725 onwards, John Steven Henslow, Charles Cardale Babington, Sydney Vines, Richard Irwin Lynch, and Harry Marshall Ward and his successors.

A chronology at the end of the work, giving dates of historical events, lives of personalities, publications and so on, would have been a useful addition. In compensation, a feature of the book is the large number of illustrations — 84 in all — depicting title-pages, frontispieces, maps, portraits, plants and other subjects. There are also illustrations of specimens from

Ray's own herbarium, from Martyn's herbarium, and an illustration of an herbarium specimen Silena maritima made by James Donn. Furthermore, a number of figures of plants are reproduced from original drawings made specially for the work by Michael Hickey. Many of the figures occupy the wide margins of the book, enlivening the pages and creating a unity between text and illustrations. A coloured reproduction of Rosa "Cantabrigiensis" from a water-colour drawing by Graham Stuart Thomas, Gardens Consultant to the National Trust, makes a charming frontispiece.

Blanche Henrey is an Honorary Associate of the British Museum (Natural History), and author of British Botanical and Horticultural Literature (Oxford University Press, 1975).

# Britain in leaf

Alan Mitchell

A SINGLE volume on trees cannot, unlike one on birds, extend its coverage to the Mediterranean shores without losing much of its use in British gardens. The Hamlyn Guide to Trees of Britain and Europe by C. Humphries, J.R. Press and D.A. Sutton (Hamlyn; hbk £5.95, pbk £3.95) is a good example. Of the total of 20 species of pears and eucalypts covered, 15 are not grown in Britain. To encompass these and some obscure southern oaks and maples, the authors have had to omit important trees like Low's and Nikko firs, and, worse, ignore all the cultivars of Lawson and Sawara cypresses which crowd our parks and gardens. The book, then, will be of most use in the field in southern Europe. It has a good, workable synoptic key, and excellent descriptions and illustrations of details, though the whole-tree drawings are seldom in the least helpful and a few are quite wrong.

Alan Fairhurst and Eric Soothill's Blandford Guide to Trees of the British Countryside (Blandford, £9.95) contains beautiful photographs of the bark, foliage, flowers and fruit of the 55 trees, 9 shrubs and ivy which are given full treatment, and of a few of the 86 trees and 18 shrubs more briefly described or just mentioned. This last, however, is quite pointless when so many common trees are omitted altogether. The marginal outline drawings are reasonably distinctive (but "Dutch elm" is plainly English elm). The strength of this book, and exceptional feature, is the long lists of fungi and insects associated with each species, and of local names for the trees. The entries for timber uses and the general information are also good value.

A particularly handsome but unpretentious little book is The Guinness Book of Trees (Guinness Superlatives, £4.50). Here, Jeanette and Esmond Harris give a useful summary of the history of trees in Britain from pre-glacial times until the present, and raise a question-mark against the native status usually accorded to the beech and hornbeam. They select 18 conifer and 32 broadleaf trees for full treatment and full-page colour illustration, mostly of high quality and of fine specimens. The order in which the species are presented seems to have no rationale but there is much interesting information about each.

Unfortunately, the maps are a disaster area. That showing the areas of the world from which most exotic species are derived shades the wrong side of South America and even manages to omit California. Oregon and Washington as well as Korea; and the map of tree-collections puts Edinburgh north of Stirling and Oxford in Cambridge. The distribution maps, in bold red and white, even for exotics planted widely, are equally eccentric. Ireland is deprived of grey poplar (the largest specimens in the British Isles are there) and Norway maple, but is covered in English elm. Nonetheless, the line-drawings of foliage are neat and attractive and the book should attract its fair share of buyers.

The International Book of the Forest (Mitchell Beazley/Simon & Schuster; £14.95, \$35) is one of those books of large format and prolific illustration in which information from the text is repeated in boxes and captions, as if to cater for those who cannot face reading the whole tome. The scope in subject, time and region is enormous — from Pangaea through mediaeval forests to modern logging; birds, nocturnal creatures and forest man, to fire and the ecosystem, a single, double-page spread for each. Forest products also take a spread each but while elaborate maps and tables of the world timber trade may have their uses, the details of boat-building and of the manufacture of rubber tyres and plastics are out of place in a book on forests which can spare only a small box for the subject of tree-breeding. The main feature of the book is the surveys of forest types of the world, including the oceanic islands and mangrove swamps, and these include some magnificent photographs.

In complete contrast, as befits its different function, is *The Reader's Digest Field Guide to the Trees and Shrubs of Britain* (Reader's Digest Association, £6.50), a stoutly bound, attractive book in an unusual broad, shallow format. It is profusely illustrated with mostly good paintings and drawings, and one high-quality photograph per page, which last is, however, too small to be of much value. Arranged according to the shape of the leaf, the plants include a wide range of shrubs and yet there is still room for a good selection of trees and some cultivars. A

broad ecological slant is given by additional coverage of the wildlife in oak woods, beech woods and other forest types. There are five spreads depicting winter shoots and two on cones, and a small section on some of the places in which to see a variety of trees. Produced to the

usual standards of Reader's Digest books, this is a good specimen of the field-guide genre and a reasonable buy.

Alan Mitchell is a Dendrologist with the Forestry Commission and author of a number of books about trees.

# Arboreal splendours and uses

Richard Howard

The Oxford Encyclopedia of Trees of the World. Consultant editor Bayard Hora. Pp.288. ISBN 0-19-217712-5. (Oxford University Press: 1981.) £12.50, \$19.95.

"Ask a child to draw a tree and he will start with the trunk, then add a fan or brush of branches". A straight, woody, selfsupporting trunk, unbranched for a distance from the base, defines a tree at least 21 feet in height to most people. Yet the botanist or the horticulturist may be uneasy with such a definition, which in this book covers ferns (to 80 feet tall), cycads, grasses (bamboo), dragon trees (supposedly 6,000 years old), tree cacti (to 66 feet), as well as the broadleaved flowering plants and the cone-bearing gymnosperms with needle-like foliage. Trees in cultivation, the primary subjects of this volume, have a history as well as individual beauty and are useful to mankind for their bark, wood, leaves, flowers or fruit.

Thirty-nine authors excel in describing. distinguishing and illustrating the 350 species covered in this volume. The "main" species of large genera are grouped together, with notes on their key characteristics, permitting the reader to identify a plant and to understand the morphological variation within the genus. Useful keys for the identification of trees are provided for conifer families and the conifer genera by families, for the broadleaved families and aberrant genera, and for the broadleaved genera by families for those plants covered in the book. The introductory essays on trunk and wood structure, the forest ecosystem, the forests of the world, and forestry practices and products are instructive evaluations of the economic problems faced by a society which is still dependent on the tree.

The photographs, maps of distribution and drawings are well done, though there are a few exceptions. The photograph of *Cornus kousa* is a disappointing representation of that handsome flowering tree, and no one would understand the attraction of the American flowering dogwood or the Pacific dogwood from the short, leafy branches used as illustrations here.

The volume is not an "encyclopedia" of trees of the world, as titled, but is certainly a handsome compilation of "trees of many kinds, primarily those grown in Europe". The treatment of the gymnosperms (conifers) is the best ever published and alone is worth the price of the book. In contrast, the section "Trees of the Tropics" is atrocious, with errors of fact (e.g. mace, Bertholletia), identification (plate of jackfruit, text on Hura crepitans), and omissions of interesting or important trees (litchi, Blighia), and with a vocabulary inconsistent with the glossary or the other articles. Fortunately it is short and, if ignored, will not detract from what is otherwise an excellent publication.

Richard Howard, formerly Director of the Arnold Arboretum, is Professor of Dendrology at Harvard University.

# Anatomy of biology

Peter R. Scott

Biology in Profile: A Guide to the Many Branches of Biology. Edited by P.N. Campbell. Pp.128. ISBN hbk 0-08-026846-3; ISBN pbk 0-08-026845-5. (Pergamon: 1981.) Hbk £8, \$19; pbk £3.95, \$9.50.

WHAT should you tell an intelligent 17-year-old about the biological sciences? How can you convey something of the range of the subject to a bright school-child faced with the many different courses which further education offers? According to the International Council of Science Unions, the proliferation of the biological sciences has now made this task too difficult for any individual to tackle. They have therefore asked a number of distinguished biologists to explain something of their own areas of specialization; the result is this collection of 20 essays. The subjects covered may all be studied at university level, and range from zoology and botany to the less-familiar psychology, endocrinology and biophysics.

The authors were asked to address themselves to intelligent 17-year-olds who are already studying biology. There is no attempt at any consistency of style; some have needed to explain the background to their subject in detail, others have chosen

to relate some of the more spectacular discoveries of the past 20 years. Many give their own personal view of where the subject might lead in the future, and what it might offer to those who follow it.

A brief essay is not a suitable format for a careful weighing of complex arguments; rather it provides an opportunity for an optimistic and sweeping review of a field. Most of the authors have responded with a light approach — nutrition is sold as a growth area — and this makes Biology in Profile suitable reading matter for spare moments. Many of the contributions assume little biological knowledge, and would also be appropriate for those thinking of taking up biology for the first time.

The treatment of biology as 20 disparate subjects may cause concern to some teachers; but overall the book does not create an impression of fragmentation. None of the authors is able to describe his own area without referring to its overlap with topics described elsewhere - indeed, the idyllic picture is drawn of scientific progress being made by the combined efforts of biologists, chemists and physicists, all working in close cooperation. Some students may be surprised to see the emphasis placed by many of the writers on quantitative work; those who see biology as the only science which does not require a firm grasp of mathematics would be well advised to choose their area of specialization carefully.

Perhaps the most surprising omission from this collection is any discussion of medicine or veterinary science. Most of those who enjoy biology at school will consider these as a career, if only because they imagine that they know what they entail. A direct comparison with the other branches of biology might have been helpful, and have removed some misconceptions.

Biology in Profile will find a place in many school libraries. It will be bought for those bewildered by the range of biological subjects available at university, but I think it should also be read by teachers seeking answers to the question "What is the point of science?", and even by non-biologists. May we hope for chemistry and physics in profile?

Peter Scott teaches science at Charterhouse School, Godalming, Surrey.

# Lightfinger

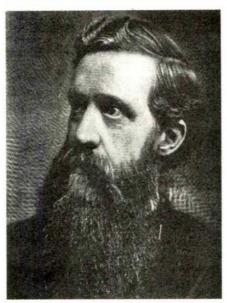

Following the success of the 1980 production, the Natural History Museum in London will this year stage "Lightfinger: A Space Fantasy for Christmas". The "fantasy" is designed for family audiences and takes the form of a science fiction comedy dealing with inter-galactic conservation and ecological problems.

The play will run from 18 December to 21 January (excluding 24-26 December and 1 and 11 January) with performances at 14.30 from Monday to Saturday, and at 15.00 on Sundays; special matinees for school parties start at 11.00.

# Elliott Coues, the combative naturalist

Clayton M. White

Elliott Coues: Naturalist and Frontier Historian. By Paul Russell Cutright and Michael J. Brodhead. Pp.509. ISBN 0-252-00802-2. (University of Illinois Press: 1981.) \$28.50, £19.95.

Elliott Coues - lover of birds yet sparrow hawk.

"A MAN with the mental calibre of Huxley and the charming personality of Mivart" — thus did Alfred Russel Wallace characterize the American ornithologist Elliott Coues; and Wallace's assessment was by no means unique. Also known for his contributions as a naturalist and frontier historian, Coues' achievements were recognized during his life (1842–1899) and he enjoyed ample publicity. The memory of his work has of course faded over the years, but this account of his life will do much to bring him back into the public eye.

Cutright and Brodhead have sifted a vast collection of hitherto unpublished material in the course of compiling their excellent biography. Capturing Coues in all his diversity, this book is for everyone; it is easy reading, yet informative and - not least — entertaining. Its 26 short chapters, refreshingly error free, draw heavily on the voluminous file of Coues' letters and his personal "Book of Dates". Each focuses on significant events in Coues' life: his time in Fort Randall (Dakota Territory), the expedition along the 49th parallel, the formation of the American Ornithologists' Union (Coues was one of the three founding fathers) and so on. Additionally, we are supplied with appendices and a bibliography of Coues' work.

Elliott Coues was an indefatigable worker and writer. His scientific career began at age 20, with a summer's excursion to the coast of Labrador. Funded by the Smithsonian Institution, he billed them the remarkable total of \$218.72 to cover his

entire summer's expenses. Three years later, as the result of work in the American south-west, he was firmly established as a naturalist; from that point his career was a steady upward climb to the apex of nineteenth-century American ornithology. He joined or was elected honorary member of 24 learned societies, among them the National Academy of Sciences, where, at 34, he was the youngest person to become a member.

His first published article appeared in 1861, even before his Labrador work; from then until his death he poured out more than 700 formal articles, edited works and other contributions ranging through science and medicine to theosophy. His literary skills matched his writing speed. His command of vocabulary, fertile imagination, ability to weave his exceptional observational acuity into the delightful fabric of his sentences and unexpected flashes of humour became trademarks of his work. To him, orioles were "gleaming through the sombre foliage like tiny meteors", whilst bushtits were "droll folk, quite innocent of dignity, superior to the trammels of decorum". Charles Lummis commented of Coues that

such a man never would have dried up to the proverbial scientific mummy. He humanized whatever he did without sacrifice of exactness. No one surpasses him in esoteric equipment; and as a 'readable' scientist, he was easily unrivalled.

While his prose would not be acceptable amid the stuffy curtness of our present scientific writing, I found it delightful:

We remember the 'rift within the lute'; in the canyon wren we have the lute within the rift — a curious little animated music-box, utterly insignificant in size and appearance, yet fit to make the welkin ring with glee.

And some passages cannot but elicit a chuckle. For weeks on end the scientific expedition along the 49th parallel had no fuel but buffalo dung for cooking and warmth. But Coues' pen was equal to the functionality of the dung:

as an agent in the progress of civilization...the buffalo chip rises to the plane of the steam engine and the electric telegraph, and acquires all the dignity which is supposed to enshroud questions of national importance or matters of political economy.

After obtaining both MD and PhD degrees, Coues was employed as an army surgeon. As such, he was often sent to remote western outposts; most of his time was spent in the pursuit of birds, however. Two of his works are directly attributable to this period: Birds of the Northwest and Birds of the Colorado Valley. Perhaps his major publication is his Key to North American Birds, an inspiration to such twentieth-century ornithologists as Ernest Thompson Seton and Frank M. Chapman. Of it, Seton wrote:

Faults it had in abundance, I now know; but it

was the first successful effort to take exact bird knowledge from the museum, and give it to the multitude, to place it within reach of all the world of those who love to hold our birds, not as skins, but as loving friends.

While birds were his main interest, he also collected other creatures. One of his prize finds was a rare western rattlesnake which he even stopped to collect while "under the untoward circumstances of a hasty retreat from hostile Indians". Although he often fought Indians, he eventually grew to champion them. While he saw what he considered defects or evils in their character, he concluded that

the Indian is neither a foreign power to be treated with, nor a wild beast to be hunted down, but a fellow-man to be reclaimed. Let us begin by calling him, that in the end we may make him, a brother.

Coues dabbled in theosophy and spiritualism. He became an exacting historian producing works on Lewis and Clark and other early western explorers, trappers and traders. But it is for his ornithological work that he will be remembered. His help to and influence upon Louis Agassiz Fuertes, undoubtedly America's greatest bird artist, is incalculable. And during his life Coues described 36 forms of bird and 18 forms of mammal new to science, many of them new genera and most of which are still recognized today.

Considering his intense and life-long love of birds, it is ironic that his most intense and persistent effort was an unrelenting war against one: the European house sparrow, recently introduced into North America. This particular bird he deeply loathed, and from the 1860s onward attacked it and its defenders with equal venom. It is doubly ironic that the main defender and thus combatant was Coues' friend, T.M. Brewer. Brewer was not spared abuse even after his death - "We . . . know that Brewer was a cantankerous old ass at the time he had the good taste to fall asleep in Jesus". Nor was Coues' work ineffective; eventually he was even accused of "treason" due to having "incited a riot" against the sparrow. But he yielded to neither the bird nor its friends; in 1878 he publically divided the bird's defenders into five categories, four of them composed of idiots and the fifth of the weak-minded.

In the long term, of course, his efforts were in vain; the sparrow has spread in North America from coast to coast and from central Canada to southern Mexico. And the final irony? Coues certainly would not have been pleased when, in 1975, the American Ornithologists' Union presented their most prestigious recognition, the Elliott Coues Award, to a team of researchers for their notable study on the evolution of the house sparrow in North

What's that (North American) animal?

Richard G. Van Gelder

The Audubon Society Field Guide to North American Mammals. By John O. Whitaker, Jr. Pp.745. ISBN 0-394-50762-2. (Knopf: 1981.) \$11.95. Harper & Row's Complete Field Guide to North American Wildlife. Eastern Edition assembled by Henry Hill Collins, Jr. Pp.714. ISBN 0-690-01969-6. Western Edition assembled by Jay Ellis Ransom. Pp.809. ISBN 0-690-01971-8. (Harper & Row: 1981.) \$12.95, £9.50 per volume.

THE purpose of a field guide is to enable one to identify an object without having that object in hand. This usually means that the criteria for identification are different from those on which the strict classification of the species is based. Nonetheless, some eminently successful field guides have been produced - birds, in particular, lend themselves to adequate field identification, to some extent because birds characterize themselves by sight and sound, two better-developed human senses. When it comes to animals with a greater dependence on odour or ultrasonics, such as shrews, rodents or bats, field identification becomes much more difficult. Despite the relative success of the "Peterson system" of field identification - drawings or paintings with "key" characteristics indicated, arranged for ready comparison — innovative attempts continue to be produced.

John O. Whitaker's Audubon Society Field Guide to North American Mammals is small enough to fit into a large pocket and is the first major attempt to utilize colour photographs for mammal identification. The 313 photographs (representing the 368 species, exclusive of whales and dolphins) are grouped rather sensibly by similar-sized and similarappearing species, even if unrelated; for instance muskrats, beavers and marmots appear together. While this may disconcert the taxonomist, it will probably aid the layman. The colour plates are followed by 403 pages of text dealing with each species, arranged in standard taxonomic order. These accounts include a description with italicized identifying characters and measurements, sign, breeding habits, habitat, range (with a small map) and excellent though concise life-history information. Marginalia often include drawings of animals not otherwise illustrated, and tracks. Appendices include a glossary and a complex "Range Chart" to

aid in the identification of some of the smaller mammals. The book is indexed and cross-referenced, but there is no bibliography.

Harper & Row's Complete Field Guide to North American Wildlife attempts to provide notes on and a source for the identification of birds, mammals, reptiles, amphibians, fish, and molluscs and other marine invertebrates of America north of Mexico. The two volumes cover the eastern and western USA, divided at the 100th meridian. This involves considerable duplication of species accounts as well as of illustrations, but not necessarily of

information — westerners are largely deprived of notes on the reproduction of mammals, for example. Within each species account there is a description, a comparison with similar species, and sadly variable and inconsistent information on habitat, habits, voice, food and range. Half of the total of 239 plates are in colour, and all are cross-referenced to the text (not always correctly or in the same volume), and "edge-marked". References are given in a section introducing each major taxonomic category.

Comparing the mammal sections, neither of these guides is superior for field identification to Burt and Grossenheider's volume, A Field Guide to the Mammals, in the "Peterson series", which has finer illustrations and maps. With Whitaker's book one is more likely to come up with a valid identification than with the Harper and Row volumes, but for most of the smaller species one has to resort to text descriptions and geographical information in both of these sources. Whitaker's small maps (without state or province boundaries) are useful, but the reader must be a good geographer to grasp the range of, for example, the Gray Myotis ("in se. U.S., from Ky., w. to Mo. and Kans., s. through Ala.") in a Harper and Row volume; the only map, on the inside of the front cover, does not identify the states.

For life-history information, Whitaker's book is the best single, concise source currently available, and for this reason is highly recommended. The larger Harper and Row volumes are a bit much for a pocket, and seem to have been planned by a committee to attract everyone, but satisfy no one.

Richard G. Van Gelder is Curator of Mammals at the American Museum of Natural History, New York.

Clayton M. White is a Professor of Zoology at Brigham Young University, Provo, Utah.

# Cyanide in Biology

edited by Birgit Vennesland, Eric E. Conn, Christopher J. Knowles, John Westley and Frode Wissing

December 1981/January 1982, xiv + 548pp., £22.00 (UK only)/\$45.50, 0.12.716980.6

This book, covering as it does all aspects of the metabolism of cyanide, should serve not only as an introduction to the uninitiated biologist, but also as a handbook for those already engaged in research in this area. This aim is undoubtedly helped by the extensive bibliography which integrates the widely scattered literature from the publications of different disciplines. Graduates and researchers in biochemistry, microbiology, plant physiology and toxicology alike will find this book valuable reading.

International Lecture Series in Computer Science

# The Correctness Problem in Computer Science

edited by Robert S. Boyer and J. Strother Moore

November/December 1981, xiv + 280pp., £14.20 (UK only)/\$29.50, 0.12.122920.3

This collection of papers describes continuing research by several internationally recognized authorities on the topic of computer program correctness. Program correctness is here viewed as a mathematical concern. To produce correct code the programmer should have at his disposal the same kinds of formal and informal tools used by mathematicians. These papers describe research by the authors aimed at producing such tools, including design methodologies, formal specification languages, mechanical program verifiers, and mechanical theorem-provers

# Cytochrome Oxidase

A Synthesis

Mårten Wikström, Klaas Krab and Matti Saraste

December 1981/January 1982, c.200pp., £14.60 (UK only)/\$30.00, 0.12.752020.

This volume provides an up-to-date synthesis of research material on cytochrone oxidase. Various models and hypotheses are used as frames for the experimental data, and themes covered include protein structure and topography of the enzyme in its isolated and membrane-bound states; physical properties; configuration and topography of the haem and copper centres, their interactions and oxidoreduction properties under equilibrium conditions; kinetics and catalytic mechanism of electron transfer and oxygen reduction; mechanism of energy transduction by proton translocation

# Honey Bee Pathology Locomotion

Leslie Bailey

December 1981/January 1982, x + 132pp., £9.40 (UK only)/\$19.50, 0.12.073480.X

The book gives a comprehensive account of all the important and common pathogens and diseases of the honey bee, with emphasis on modern knowledge of their natural history, especially of their ecology within the insect society, and with attention to their place in the pathology of Insects in general. Diagnostic methods, including previously unpublished techniques for cultivating and purifying microbial pathogens and viruses are described; and treatments for diseases are reviewed and discussed.

# **Bioenergetics**

An Introduction to Chemiosmotic Theory **David Nicholls** 

January/February 1982, c.180pp., Casebound: £13.40 (UK only)/\$27.50, 0.12.518120.5 Paperback: £5.50 (UK only)/\$11.50 0.12.518122.1

In the 1960s. Peter Mitchell put forward a theory which revolutionized our understanding of bioenergetics. Called the Chemiosmotic Theory, its essence is fundamentally simple. Nevertheless, general biochemistry texbooks deal with it only superficially and the research literature is unapproachable for the uninitiated. This book has been written with the aim of introducing the subject from first principles, and then discussing particular aspects in sufficient detail to enable the reader to tackle the primary sources.

# **Biomass as Fuel**

L.P. White and L.G. Plaskett

November/December 1981, x+212pp., £14.20 (UK only)/\$29.50, 0.12.746980.X

Despite wide research and considerable advances, there have been few publications offering a comprehensive review of the subject in any depth. The authors of this book have identified this need and set out here the feasibility, time-scales and overall potential of the many possibilities. They explore the resources presently and potentially available and the techniques necessary to exploit them. These include animal and crop farming on land and short rotation forestry; the harvesting of natural vegetation; mariculture and the mass cultivation of micro-algae.

# **Energy Metabolism** of the Cell

A Theoretical Treatise J.G. Reich and E.E. Sel'kov

November/December 1981, c.302pp £36.00 (UK only)/\$74.00, 0.12.585920.1

This monograph is primarily a theoretical treatment of cellular energy metabolism, which requires a good background knowledge of biochemistry on the part of the reader, but a modest knowlege of mathematics. By searching for compact kinetic blocks of metabolites and reactions, the authors aim to simplify the complex schemes of biochemical pathways and present an integrated picture so that the performance of the system as a whole can be studied

Symposia of the Zoological Society of London

# Vertebrate

edited by M.H. Day

September 1981, xviii + 472pp. £37.20 (UK only)/\$89.50, 0.12.613348.4

This volume is based on a symposium held in London on 27th and 28th March 1980, under the joint sponsorship of the Zoological Society of London and the Anatomical Society of Great Britain and Ireland. The way in which vertebrates move constitutes a sector of animal biology that is of great evolutionary significance, as the ability of move in an effective way may be absolutely vital to survival and evolutionary

FIFTH EDITION

more than 14 000 Entries for aromatic compounds. 10 000 for heterocyclics, 12 000 for aliphatics and alicyclics, 12 000 for natural products, and 1 500 for organometallics

Heilbron's Dictionary of Organic Compounds consists of an alphabetical listing of the most common and important compounds likely to be encountered by chemists, biochemists, pharmacologists and biologists working with academic, industrial and government organizations. For more than 40 years the DOC has provided these scientists with the most simply presented and easily accessed information on the structures, alternative names, physical and chemical properties and leading references for core organic compounds. DOC 5represents the most radical and comprehensive revision undertaken, executed to rigorous standards of scholarship with the needs of the practising scientist in view.

# FEATURES OF THE NEW EDITION

- Enhanced compound selection. Elimination of obsolete and less relevant compounds to make room for: 1) most fundamental organic compounds of simple structure 2) all important natural products, and 3) comprehensive coverage of compounds of widespread industrial or commercial use. Specialists have been responsible for the selection and compilation of Entries within each division of organic and industrial chemistry.
- 35% of Entries in DOC 5 are completely new, all remaining Entries have been revised and updated.
- New types of information provided include stereochemistry, hazard and toxicity data, labelled references and CAS Registry Numbers. All structure diagrams have been redrawn to a new standard.
- Compounds are still referred to by their most familiar names - IUPAC - based systematic names where appropriate, but trivial names for most natural products. A large number of synonyms are included.

# **Publication** September 1982

(special price for fully paid pre-publication orders: £850)

(special price for fully paid pre-publication orders: \$1690)

- Four indexes chemical Name, Formula, Heteroatom, and CAS Registry Number provide users with multiple entry points for searches.
- Increased compatibility within the chemistry library or information centre. The labelled references in each Entry provide a direct link to the key primary literature on any compound, and the presence of CAS Registry Numbers formed a bridge to all printed publications and computer-based services which incorporate CAS Registry Numbers
- DOC 5 will be kept up to date with annual Supplements, incorporating a new unique system of cumulative indexes These will ensure the continued ease-ofuse of DOC 5.
- More than ever, the need in chemistry is for a cost-effective and time-saving source of structure and property information that is attuned to the requirements of its users. Wide-ranging, selective, and outstandingly easy-to-use, DOC 5 is planned to fulfil such

The Snouters: Form and Life of the Rhinogrades. By Harald Stümpke. Pp.118. ISBN pbk 0-226-77895-9. (Chicago University Press: 1981.) \$4.95, £3.50.

CATS, rats, mongooses and above all mankind have caused over 300 extinctions of vertebrate animals during the past 300 years. This rate is far greater than estimates of that of the dinosaurs' extinction at the end of the Age of the Reptiles in the late Cretaceous period. David Day's The Doomsday Book of Animals describes something of the biology, in many cases all the known biology, of these 300 vanished species and subspecies, and chronicles their final days. The style is factual and unemotional, but the book generates a great feeling of sadness as page after page records loss after loss. Those perceptive of the value of retaining the world's biological diversity will feel something of the corporate guilt that rests on Homo sapiens as the destroyer of that diversity.

By far the greatest losses have been suffered by island communities, with only 75 animal species or subspecies disappearing from the continental land masses including Australia. Of these, 16 are fish which died out as their small "aquatic islands" in North America were tampered with.

Whilst the introduction of cats, rats and mongooses, whether intended or accidental, has logically resulted in the extinction of many rare endemic island species and subspecies, particularly in the West Indies and the Mascarenes, in other instances it is almost inconceivable that a species could disappear because of the sheer size of its population. The extinction of the passenger pigeon is perhaps the most astounding case since it was probably the most abundant bird species in North America. Flock sizes of between one and two million birds were reported not 50 years before the very last passenger pigeon died in Cincinatti Zoo in 1914. They were hunted relentlessly for sport, food and quack medicine, and as the flocks became more scattered so the telegraph system was used to direct the hunters' efforts. Man the hunter does not operate as do other predatory species which switch to alternatives when favoured prey are uncommon thus allowing the preferred prey to recoup its losses. Rather, he develops tunnel vision and having formed a search image is unable to switch to another prey until forced to

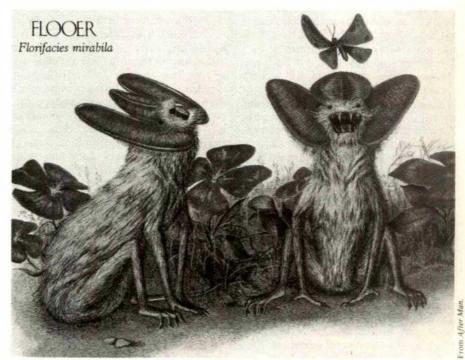

because that prey no longer exists. It is a characteristic of the examples in the *Doomsday Book of Animals* that as a species becomes rare through man's hunting pressure, so man's efforts against that species have tended to increase. Although there may be an awakening enlightenment that the world's diversity of species needs to be conserved, David Day's beautifully illustrated and poignant book ends pessimistically by reminding its readers that there are currently over 400 critically endangered species, many of which will become extinct in the near future.

When human beings themselves become extinct and take with them many of the groups of animals we know today, new life forms will evolve to fill the resulting ecological lacunae. This is the basis of Dougal Dixon's look into the future, 50 million years hence. Although After Man is fun, and displays some imagination, the biological framework within which it purports to operate is clearly little understood. In many cases the futuristic species just could not follow the lifestyle attributed to them. What happens to the leaping devil (Daemonops rotundus), a sort of carnivorous jerboa, after it has sunk its needle teeth into a large lizard? It has neither the apparatus nor the capacity to do much else unless it swallows the lizard whole and becomes the rolling devil. How does the gigantelope (Megalodorcas giganteus) actually eat the bulbs and roots it grubs up with its splendid horns, which extend in front and below the animal's muzzle and prevent its getting near the ground? The book is shot through with biological anomalies and lacks credibility despite the introduction by Desmond Morris, who should have known better than to attribute the book with "real scientific value".

Whereas After Man tends to be conservative in its conception of alternative life forms, Harald Stümpke's (alias Gerolf Steiner) zoological fantasy is highly inventive. Absent from the bookshops for the past ten years, the reprinting of The Snouters has been long overdue. It is an account of the adaptive radiation of a small group of insectivorous mammals which are characterized by the extensive development of the nose or nasarium. Among the 189 species in the order Rhinogradentia the nasarium is variously used temporary support while the legs serve for food processing; as an adhesive organ in the sedentary species; as a jumping organ in the hopsorrhines; and in the polyrrhines it becomes sub-divided into foot or tentacle structures. Throughout this bizarre but fascinating account the form and function are minutely examined in true Germanic taxonomic style.

Such realism will endear *The Snouters* to those with a zoological background but students should beware the rhinogrades, they are prime spoof material for inclusion in vertebrate courses. However it may be amusing to see whether straight faces can be maintained when the feeding habits of *Nasobema lyricum* are explained. This beast feeds on fruits which it reaches by, to put it politely, passing wind into its inflatable tail thus momentarily producing a long rigid appendage with a grasping tip.

Bryan D. Turner is a Lecturer in Zoology at King's College, University of London.

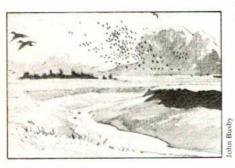

The insectivorous flooer (Florifacies mirabila). The animal has glands around its mouth which produce a sweet-smelling secretion and attract the flooer's prey.

# Some help for the dudes and praise to the experts

John Andrews

BIRDWATCHING beginners are badly served by publishers, their needs being met neither by the abundant field guides, which are mostly too wide-ranging and complex for the newcomer, nor by the glossy coeditions "packaged" to sell in several countries rather than to inform in one. One bright side to the recession has been that the latter have vanished from the scene, though it may be mere coincidence that two books have appeared which every beginner should own.

John Gooders' The Bird Seeker's Guide (André Deutsch; hbk £6.95, pbk £3.50) gives invaluable instruction on where to find birds in Britain. The opening chapters contain general guidance on the ways in which bird populations change with the seasons and on the characteristic group of species or

"bird community" to be found in each major habitat type. The main text comprises species accounts, each containing brief identification notes which concentrate on key points for separating similar species, and a description of the preferred habitats and distributions. Where necessary for uncommon species, likely locations are given but commendable care has been taken to avoid reference to precise sites in the case of vulnerably rare birds.

Anyone venturing into the field and encountering other birders will rapidly come up against the substantial jargon of ornithology, which ranges from arcane scientific terms to offensive slang. For instance, there are about 40 different areas of a bird's plumage each with its own name and one must know them all to make clear written descriptions of birds seen in the field: if you don't, you are clearly a "casual birdwatcher without serious commitment" or, more succinctly, a dude. No longer need you flounder in ornithology's information gap. The Birdwatcher's Dictionary by Peter Weaver (T. & A.D. Poyser, £5) defines over 1,100 terms and abbreviations, to enable the newly-fledged birder to match insult or erudition with equal ease. Crisply illustrated by Mike Hodgson, the text is thoroughly instructive and makes good browsing as well as useful reference.

By contrast with the needs of the beginner, scientific ornithology in Britain is usually well served by carefully researched and presented books. This year has seen only a single addition to the list but one eagerly awaited by the great number of amateur ornithologists who contributed to the Birds of Estuaries Enquiry, which ran from 1969 to 1975. Every winter for those six years the total wader populations of all the estuaries of Britain and Ireland were counted in perhaps the most ambitious and demanding ornithological survey ever undertaken. Substantial organization was needed to find and coordinate the teams working each area. Few of the thousand people who took part began as skilled wader counters, so techniques had to be evolved, imparted and checked for accuracy. Some personal commitment was also required: it is no light task to rise in the January small-hours, drive to a distant estuary for a dawn high tide and strive to count whirling flocks of birds, sometimes many thousands strong, with rainspattered lenses or frost-numbed fingers. Now the intangible and sometimes illusive rewards of the experience take a more practical form in A.J. Prater's Estuary Birds of Britain and Ireland (T. & A.D. Poyser, £14), which draws together the results of this mammoth study and much more information besides.

The opening chapters examine the nature of estuaries and the ways in which birds utilize them, including consideration of the factors which influence feeding success. Turning to migration and distribution in Western Europe, the author, who was the national survey organizer, discusses in particular the complexity of wader movements between estuaries which ringing work is now unravelling. Two chapters are devoted to threats to estuaries barrages and reservoirs, airports, agriculture, energy generation, pollution and leisure all figure. This is a slightly disappointing section of an otherwise excellent work, with too much emphasis on the nature and scale of impact and too little on the causes and justification - or lack of it - for the threats themselves: some startlingly costly and grandiose ways of wasting public money continue to be dreamed up for our estuaries. Returning to his main theme, Tony Prater describes the organization of the Enquiry, discusses count methodology and considers the vexed question of assessment criteria.

About half of the text comprises detailed summaries of present knowledge, both estuary by estuary and species by species. Copious maps and tables make much of the textual information available at a glance: there is an excellent bibliography, some photographs of marginal usefulness and many charming drawings by John Busby. Overall, a valuable book of a remarkable survey. Other nations please copy.

In turn, Britain, overrun by mink and, to some opinions, by Canada geese, might do

well to copy Western Australia in evolving a firm policy to control importation and translocation of potentially harmful wildlife. As a step in this direction, the States Agriculture Protection Board initiated a study which became, in the hands of John Long, the author of Introduced Birds of the World (David & Charles, £15), a comprehensive review of every known avian introduction worldwide. He found records involving 425 species and for each describes its natural and introduced range, the history and outcome of its introduction, and discusses its potential for damage. And damage there has been - extinctions of native species through competition and hybridization, substantial losses of agricultural and fruit crops and, possibly, the transfer of diseases and parasites. Western Australia is to be congratulated on the book: would our own agriculture departments were as wise.

John Andrews is Head of Conservation Planning at the Royal Society for the Protection of Birds, Sandy, Bedfordshire.

# The dissent of woman

Andrew Hill

On Becoming Human. By Nancy M. Tanner. Pp.373. ISBN hbk 0-521-23554-5; ISBN pbk 0-521-28028-1. (Cambridge University Press: 1981.) Hbk £20, \$29.95; pbk £6.95, \$10.95.

CHIMPANZEES are more like human beings than they appear. Linnaeus — the type specimen of taxonomists — originally classified the beasts in the human genus as *Homo troglodytes*, and scientists have continued to stress the similarities. *On Becoming Human* follows this tradition by proposing the chimpanzee as a model for the common ancestor of apes and man.

The book possesses a number of attractive features. Some of the latest evidence of affinity comes from work on proteins, and here we have a useful summary. There is also much on chimpanzee behaviour, emphasizing the

role of females in their societies, and in evolution as well. Importance is attached to social factors in evolutionary change, to cooperation rather than competition, and to the probable significance of plants both as food and as material for tool making. This information, along with details of fossil finds, is put together to provide a story of human evolution that more or less fits with what is known. But after all, so little is known — although this has never been a drawback for theorists in evolutionary anthropology.

In addition, the book has unfortunate aspects. Palaeontological objections to assessments of phyletic divergence times based upon protein work are not thoroughly explored. The description of chimpanzee behaviour is not adequately set in the context of broader primate ethology, and is needlessly anecdotal rather than being presented in a rigorous scientific manner. Given the aim to show the role of female sociability as a force in human evolution, the chimpanzee female is not a particularly good analogue, since its social network is more restricted than those of many other higher primates. Further, there are things to object to in the palaeoanthropological sections as well, such as an idiosyncratic view of stratigraphy.

Perhaps worst, the text itself has been seriously affected by the contemporary problem of inflation. The material could have been better organized, and the style is very repetitious (with frequent parenthetical interruptions) and often says the same thing twice (or more). The maps are so reduced that it is impossible to see whether they would convey information even if larger, and the illustrations are inappropriately cute and sketchy for work of whatever sort this is — indeed it is difficult to guess for whom the book is intended.

Models have a limited value; plausibility is about the only thing they satisfactorily demonstrate. They raise questions and illustrate possibilities, for it is likely that transitional hominids were at least as complex as chimpanzees. But they can produce a confining and chauvinistic outlook. Tanner appears to reject anything that smacks of reductionism, but surely more reliance can be placed upon conclusions derived from a larger taxonomic base, from a method that aims to detect general principles. What are the consistent social correlates of a long life, for example, or a long period of infant dependence, in a wider range of mammals?

Anthropological beliefs are the product of their time, and while attempting to expose this and the role of nineteenth-century British male prejudice, I feel that Tanner falls into much the same trap by infusing her treatment with the equally parochial attitudes of some contemporary American women.

Andrew Hill is a Research Fellow at Harvard University.

# Animal behaviour from A to W

Thomas E. McGill

The Oxford Companion to Animal Behaviour. Edited by David McFarland. Pp.657. ISBN 0-19-866120-7. (Oxford University Press: 1981.) £17.50. To be published in the US early next year.

THE 1973 Nobel Prize for Physiology and Medicine was awarded to the animal behaviourists Karl von Frisch, Konrad Lorenz and Nickolaas Tinbergen. That event was, of course, the major landmark in public recognition of the discipline. But it is still gratifying that Oxford University Press has selected animal behaviour as the subject of the first of their scientific "Companion" series.

The book "has been designed as a nonspecialist introduction to the study of animal behaviour". It contains an alphabetical series of 227 articles by McFarland and 71 other contributors. The essays, from Abnormal Behaviour to Wildlife Management (no Zoos?), range in length from a few lines - on, for example, immobility and gregariousness - to 18 pages on the history of animal behaviour. Many of the articles include excellent illustrations. The volume ends with a bibliography of 146 books and with indices of both the common English names and the scientific names of animals. Each index indicates the articles where a particular species is mentioned.

Six articles are devoted to people — the three Nobel laureates plus Charles Darwin, Ivan Pavlov and B. F. Skinner. The essays contain a brief biography and a discussion of the contributions of these luminaries.

While the book is designed for the layman, many will find it useful in teaching. For example, a two-paragraph article on vacuum activities provides some interesting examples and discusses how these behaviours might occur through stimulus generalization. A cross-reference leads to an article on generalization, containing other cross-references, and also a reference to the bibliography.

Aside from the inevitable unevenness of an edited work, the book has a major deficiency. It contains no listing of the titles of the articles, neither in a table of contents nor in an index. Thus one is left to guess the title of a particular subject. For example, while a scientific society and an international journal are called "Behaviour Genetics", there is no listing under that topic. Instead, the material is found under Genetics of Behaviour. There are no articles entitled Biological Clocks, Biorhythms or Circadian Rhythms; the relevant material is discussed in the contributions on clocks and rhythms. There is no entry for sociobiology (surely this topic deserves at least a crossreference).

Guessing and page-turning proved mildly annoying, so I made my own list of

the articles. I would advise others to do the same since this list proved a great aid in finding material and in browsing amongst unfamiliar topics. Certainly, there is treasure in this valuable book, but much of it is buried.

Thomas E. McGill is Chairman and Hales Professor of Psychology at Williams College, Williamstown, Massachusetts. He is editor of Readings in Animal Behavior, now in its third edition.

# The IQ agony aunt

Steve Blinkhorn

Straight Talk About Mental Tests. By Arthur R. Jensen. Pp.269. ISBN US 0-02-916-440-0; ISBN UK 0-416-32300-6. (Free Press, New York/Methuen, London: 1981.) \$12.95, £8.95.

WITH a publisher's blurb that would do credit to a headache remedy advertisement, and a shoulders-squared, plain brown wrapper of a title, Jensen's latest offering is a curious mixture. Part textbook, part highbrow agony column, it proclaims itself to be a plain man's guide and largely eschews mathematical formulae and reference to source material. But despite the obvious good intentions the book turns out to be no more than a competent rehash, lacking the brash vigour of Eysenck's brand of popular psychology and failing to compensate with novelty of argument or perspective.

What, after all, is there new to say about mental tests? Not enough, apparently, to merit a whole book, since the predominant theme of this one is the primacy and genetic determination of general intelligence, rather than the mental tests of the title. This is not to say that there is any evidence of lack of competence. As in Bias in Mental Testing (Free Press/Methuen, 1980), clearly the elder brother of this volume, Jensen shows considerable mastery of the issues. And when it comes to the evaluation of the role of IO measurement for practical purposes, there is no evidence of support for the kind of gee-whizzery and technical witch-doctory that mental tests can attract. It needs to be said by such as Jensen that tests are overused and often misused, but not thereby rendered useless, and he makes the point clearly and sensibly.

It is all the more difficult, then, to understand why he finds it necessary to pick continually at the scab of black-white IQ differences, why two of the six titles in the select bibliography concern race, indeed why he could not confine himself to the matter of mental tests, the jargon and technology of which are as often misunder-

stood amongst psychologists as in the world at large.

In the final chapter, switching from solid, textbook prose to a question-and-answer format suggesting the world's most degree-laden agony aunt, Jensen treats the reader to a glimpse into his postbag.

- "My father is a world-recognized genius. Yet I am sure he would flunk any IQ test. What do you think of that?"
- •"What can I do for my child to raise his IO?"
- o"Is our national IQ declining?"

No doubt these are genuine extracts from letters the originals of which are available for inspection at the author's premises. The format of this chapter certainly conveys the impression of an attempt to provide a plain man's guide, but at the same time shows up the failure of the enterprise as a whole. For what Jensen has done is not to strip off inessential technicalities to reach a wider audience, but to present himself as the man in the white coat and invite confidence in his knowledge and expertise. He lacks neither, but the suspicion always lurks that he is too much of an interested party to be wholly dispassionate.

Steve Blinkhorn, a Senior Lecturer in Psychology at Hatfield Polytechnic, is currently working at the Neuropsychology Laboratory, Stanford University.

# The naturalist's art

T.R. Halliday

ART and natural history have always been closely associated. But, over the past hundred years, illustrations have fulfilled a variety of functions in the natural history literature; the purpose of some is simply to aid identification, of others to be purely decorative and of yet more to encapsulate some aspect of the natural way of life of the creature portrayed. A number of recently published books not only enable us to trace the development of art in natural history from the nineteenth century to the present day, but to see how different artists have been concerned with one of these aims more than another.

A new, selected reprint of the Reverend F. O. Morris's British Birds, first published in parts between 1850 and 1857, serves to show how far natural history illustrations have progressed in the past 130 years. This reprint (Webb & Bower/Holt, Rinehart & Winston; £20, \$40) has a brief introduction by Tony Soper, describing the aims of Morris's work and its impact on the public of his time. The coloured engravings by A.F. Lydon often bear only superficial resemblance to their subjects, the poses being wooden and unnatural; they can have been of little value as guides to the identification of living birds in the field. The worth of a reprint such as this is entirely historical. The book is of no use as a guide for a modern bird watcher but does, through its text, give an insight into the understanding that early ornithologists had of birds.

An artist generally recognized as one of the early masters of bird painting was John Gould, who died in 1873. A beautifully produced volume, John Gould's Birds (A&W Publishers, New York; \$39.95 until December 1981, \$50 thereafter), reproduces a rich selection of his finer work. Maureen Lambourne's introduction provides a biographical sketch of this productive and much-travelled artist. Gould's paintings are essentially decorative and are mostly in the form of vignettes, with the subject posed against foliage or a hint of landscape. Some of his work was remarkably ambitious, such as his painting of a barn swallow feeding her young in flight. His cock pheasant, far from being shown in its customary splendour, is portrayed lying dead in a snare. Gould's scrupulous attention to detail shows, not only in his birds, but also in the plants with which many are framed. Though his pictures are often stilted and contrived by today's standards, Gould's skill and accurate observations make this book a pleasure to look through.

The latest tribute to Archibald Thorburn, who died in 1885 (Thorburn's Landscape by John Southern, published by Elm Tree Books at £12.50), reproduces many of his larger paintings, in which as much attention is devoted to the landscape as to the birds. Most of the paintings are of game birds and are set in moorland, mountains and forest. Thorburn's skilful treatment of light, dark and colour beautifully evokes the chill of autumn or the bleakness of a snow-covered mountain side. Like Gould, Thorburn sometimes attempted a painting more ambitious than a posed group of birds, such as a peregrine killing a mallard in flight or a group of ptarmigan cowering as an unseen golden eagle casts its shadow over them. His rich use of colour and intimate knowledge of the habits of birds make this a fine book.

Following his death in 1979, a number of books have been published that display the work of Charles Tunnicliffe. Robert Gillmor edits and introduces the latest of them, Sketches of Bird Life (Gollancz; £10.95). Most of the book is devoted to Tunnicliffe's field sketches that provided the raw material for his major paintings. An interesting feature of this book is the way that it shows how the artist developed his work from field sketch to finished painting; more examples of this would have been welcome. The sketches, mostly in pencil or watercolour, reveal that Tunnicliffe was not only a supreme artist, but also a fine ethologist. Behavioural interactions between birds are beautifully recorded, both visually and in the annotations that appear on many of the sketches. Tunnicliffe's extreme devotion to his art was remarkable, as shown by his meticulous paintings of dead birds which, together with his field sketches, he used in the creation of his finished paintings.

The work of a new, living artist is presented in Keith Brockie's Wildlife Sketchbook (Dent/Macmillan, New York; £9.50, \$19.95). Working in Scotland, Brockie has carried on the Tunnicliffe tradition, never missing an opportunity to record a scene, a flower, a piece of driftwood or a dead bird, as well as patiently sketching living animals from a hide. Working mostly in pencil, crayon and watercolour, Brockie has the gift of being able to catch the essence of an animal, whether it is a bird, a fish or a rabbit. All that this attractive book lacks are some examples of how the artist might use his sketches to produce more formal paintings.

In sharp contrast, the contemporary American artist Robert Bateman specializes in huge paintings, beautifully

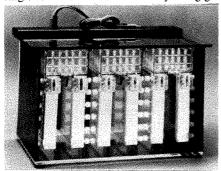

Three redstarts (Phoenicurus phoenicurus phoenicurus) painted by John Gould.

reproduced in The Art of Robert Bateman with text by Ramsay Derry (Viking/Allen Lane; \$40, £20). Bateman's breathtaking pictures are not pretty portraits of animals. His aim is clearly to emphasize the close relationship between an animal and its environment and, in many of his paintings, the animals seem to take second place to the landscape. There is much variety in the scope of his view, from panoramic vistas of Arctic tundra or the East African plains to restricted glimpses up into a tree or through the window of a derelict house. Bateman is an artist of many skills. Not only are his birds and mammals painted with exquisite accuracy of detail and posture, but his use of light and colour perfectly captures the icy cold of the tundra and the heat of the Serengeti plain. These are remarkable paintings that repay long and careful study, and this book stimulates a keen desire to see the original works.

Tim Halliday is a Lecturer in Biology at the Open University, and an author and illustrator of a number of books on natural history including Sexual Strategy (Oxford University Press, 1980) and Vanishing Birds (Penguin, 1980).

Electrophoresis unit. For two-dimensional or multiple one-dimensional electrophoretic separations, Hoefer Scientific Instruments have introduced a new multislab electrophoresis unit. The SE700 has three upper buffer chambers, each containing two 16 cm-long slabs. All six gels are run in identical conditions because all three upper buffer chambers fit into a single lower buffer chamber. By using gel

divider plates (SE6122) the SE700 can be set up to run 12 gels simultaneously. As the SE700 is designed primarily for twodimensional work, the unit needs no special cooling apparatus; temperature is regulated by the buffer surrounding the gel sandwiches.

Channel plate photomultiplier. Instrument Technology produce a M.C.P. photomultiplier featuring a rise time of less than 400ps. It can be supplied unmounted or in a 50- $\Omega$  matched mount. There is a choice of two or three channel plates, giving gains of up to  $5 \times 10^6$ , with a transit time of 1 ns and jitter less than 100 ps. Using a magnesium fluoride input window, UV response extends to 110 nm with solar blind option. Circle No. 102 on Reader Enquiry Card.

Energy dispersive X-ray detector. With the introduction of the EXTRA (extended range) detector, Kevex has brought carbon, oxygen and nitrogen within the analytical capability of energy dispersive X-ray microanalysis in the scanning electron microscope (SEM). This window detector operates in four positions, and allows the analyst to choose a window material to suit the situation. A bellowssealed motion and ion-pumped crystal vacuum ensure the vacuum integrity of the system. As the detector has a small outside diameter, it can be fitted to almost all SEM chambers and guarantees the shortest possible sample to detector X-ray path. Circle No. 114 on Reader Enquiry Card.

Low pressure inlet filter. Now available from Scientific Systems, Inc. is a low pressure inlet filter for HPLC pumps. It features a compression fitting that requires no wrenching to assemble. A knurled 316 stainless steel cap and Tefzel CPI ferrule seals on 1/8-inch diameter Teflon tubing when finger-tightened on to the threaded 316 stainless steel filter holder. The cylindrical filter element is made of corrosionresistant Hastelloy C. The filters are standard 10-um porosity to protect delicate pump components from mobile phase particles, while introducing very little pressure drop.

Circle No. 104 on Reader Enquiry Card.

Cell sorting system. Bio-Rad's Affi-Gel cell sorting system is a new affinity chromatography technique that efficiently separates B and T cells, as well as other cell subpopulations, according to their surface characteristics. The separation yields pure and viable cell populations, and is completed in 21/2h. Each system includes a siliconized Econo-Column, an outlet tube to control flow and lyophilized Affi-Gel cell sorting beads. Three different systems are available: to bind cells labelled with mouse immunoglobulin, rabbit immunoglobulin or any fluorescent ligand.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the iournal.

Cell disruption. The Bead-beater homogenizer from Biospec Products consists of a solid Teflon impeller that rotates at high r.p.m., forcing thousands of minute glass beads contained in a specially shaped vessel to collide. Even highly resistant yeast are completely homogenized in 2-3 min. This non-foaming method preserves delicate enzymes and organelles and no irritating aerosols are formed. The Bead-beater is designed to handle batches of cells of up to 150 g (wet weight) biomass.

DEPARTMENT OF GENETICS

# RESEARCH ASSISTANT

position is available, from January 1982, for 2 years, on a esearch project funded by the Zancer Research Campaign, for a graduate or MSc research assistant; xperience with living mice and nouse cytology would be an idvantage but not essential. Salary at ige 23 £5,680.

Further details may be obtained rom Dr Margaret E Wallace to whom applications, with the names of two referees, should be sent to each her preferably by 31st December 1981, Department of Benetics, Downing Street Eambridge CB2 3EH. Tel: 69551. Street,

#### **BIOLOGY TEACHING OVERSEAS**

Positions open in Biological Sciences at American University of Beirut for the academic year 1982-83. Applications are invited for positions in the following specialties: developmental biology, plant biochemistry plant taxonomy/anatomy. PhD required; rank and salary depend on experience and qualifications, but normally appointments are in the rank of Assistant Professor. Usual contract is for three years.

Curriculum vitae and three letters of recommendation should be forwarded to Chairman, Biology Department, American University of Beirut, Beirut, Lebanon. An Affirmative Action/ Equal Opportunity Employer

(NW120)A

BIOINORGANIC Postdoctoral osition available immediately for biochemist with interest in molecular structure. Successful candidate should have experience or working knowledge of biochemical techniques (microbial culture, chromatography, radioactive labelling, etc) to be used in research on siderophores and other secondary metabolites. Excellent opportunity to learn single crystal x-ray diffraction. Send curriculum vitae & transcripts & arrange for two letters of recommendation to be sent to Dr D van der Helm, Chemistry Dept, University of Oklahoma, Norman, OK 73019 (405-325 5831). A complete job description is available. The University of Oklahoma is an equal opportunity/ affirmative action employer.
(NW135)A

# **AUSTRALIA** CSIRO **Plant Biologist** (Research Fellow)

\$A19,662 - \$A28,564 pa Division of Plant Industry Canberra ACT

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,500 employees — 2,700 of whom are research and professional scientists located in divisions and sections throughout Australia.

General: The Division carries out research on problems fundamental to agricultural production. Its Genetic Resources and Biosystematics Section is concerned with increasing taxonomic and evolutionary knowledge of the native Australian flora and with the collection, conservation and utilization of genetic variation in crops and pasture plants.

Duties: Undertake research concerned with the population genetics and utilization of Australian wild relatives of cultivated plants. This will involve team research based on studies of genetic heterogeneity, reproductive biology, disease resistance, applied breeding and testing. The appointee will be required to contribute to one or more projects using relevant techniques which may include experimental crossing, fertility and compatibility testing, cytology, electrophoresis, yield and quality testing.

Qualifications: Applicants should have a PhD degree in an appropriate field or postgraduate research experience of equivalent standard or duration supported by satisfactory evidence of research ability.

Tenure: The appointment is for a fixed term of 3 years. Superannuation benefits available.

Applications: Stating full personal and professional details the names of at least two referees, and quoting reference No. A4695 should reach: The Chief, Division of Plant Industry, CSIRO, PO Box 1600, Canberra City, ACT 2601, Australia by 1 January 1982. (003)A

# MEMORIAL UNIVERSITY OF NEWFOUNDLAND

Canada

FACULTY OF SCIENCE **HEAD OF THE** DEPARTMENT OF PHYSICS

Applications and nominations are invited for the post of Head of the Department of Physics at Memorial University, Applicants should be able to demonstrate ongoing and outstanding achievements in research in a field of physics compatible with the interests and development of the Department. They should also be committed to maintaining and further developing a strong under-graduate and graduate program. This position offers a unique opportunity to interact with new developments in the University and the Province.

The appointment will be at the rank of Full Professor, to take office by 1st September 1982 or such other time as may be mutually agreed. Salary will be negotiable and related to qualifications and experience.

Applications and nominations Applications and nominations should be forwarded, not later than 15 February 1982, to: The Dean of Science, (Dr P J Heald), Faculty of Science, Memorial University of Newfoundland, St John's, Newfoundland, Canada AlB 3X7, from whom further particulars can be obtained. be obtained.

Canadian Government policy requires the statement: "Canadian citizens and/or landed immigrants "Canadian will be given the first consideration from amongst applications received to this first advertisment." (018)A

#### YALE UNIVERSITY

DEPARTMENT OF GEOLOGY AND GEOPHYSICS

Applications are solicited for a faculty position in solid earth geophysics to begin in the academic year 1982-83. Areas of interest to the Department include seismology, exploration geophysics, mechanical and physical properties of rocks and minerals, geomagnetism, and tectonophysics.

Yale University is an equal opportunity/affirmative action employer. and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications and the names of three or more referees should be sent by 31 December 1981 to Robert B Gordon, Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven CT 06511. (NW134)A

#### ASSISTANT PROFESSOR **PHYSIOLOGY**

The Department of Physiology at the University of Minnesota invites applicants for a tenure-track appointment at the Assistant Professor level beginning about July 1, 1982. Selection will be based primarily on demonstrated research excellence. Applicants must have at least one year of postdoctoral experience and be prepared to carry out independent research.

The research must be in the field of cellular physiology, preferably involving one of the following areas: membrane transport, intracellular ionic concentration measurements, single channel studies, quantitative biology of excitable membranes, membrane reconstitution of transport proteins. The applicant will be expected to participate in the graduate and undergraduate teaching programs of the department.

Send curriculum vitae, including undergraduate and graduate transcripts, a summary of planned research and the names and telephone numbers of three references to: Search Committee, Departmen of Physiology, 6-255 Millard Hall 435 Delaware Street SE, University Minnesota, Minneapolis Minnesota 55455.

The University of Minnesota is a equal opportunity educator and employer and specifically invites ar encourages applications from womeand minorities. (NW120)A

# Director of Regulatory Affairs

# **European Region**

G. D. Searle & Co. have a rapidly expanding pharmaceutical/consumer products business in Europe with an enviable track record of success and growth. The Regulatory Affairs Department, located at the UK head office in High Wycombe, plays an integral part in this process and we are now seeking a senior professional in this field to head up the Team.

The Department is responsible for providing a full regulatory service in terms of obtaining approval for clinical studies, new product licensing and maintenance of existing licenses for each country within the European region. The region includes the British Isles, Continental Europe, Africa, Middle East and Western Asia. The successful candidate will report directly to the European Vice President of Marketing and Business Development, have a functional relationship with the Director of International

# c. £16,000 plus car

Regulatory Affairs and manage a group of nine staff

Candidates must have had at least five years' experience in a senior regulatory position in a major pharmaceutical company and hold a Science degree. A good working knowledge of French or German would be particularly useful and experience in a research establishment would be desirable but not essential.

In addition to the salary and car, Searle offers a competitive fringe benefit package plus generous assistance towards home relocation.

Please apply enclosing details of career to date to Mr. J. N. Williams, Personnel Manager, Searle Pharmaceuticals, P.O. Box 53, Lane End Road, High Wycombe, Bucks HP12 4HL,

or telephone High Wycombe 21124.

# THE INSTITUTE FOR ADVANCED STUDY

will have several openings for nembers in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-loctoral or higher level and applicants will be selected on the basis of heir ability to do research in the areas of elementary particles, mathenatical physics, astro-physics, plasma physics, general relativity and tatistical mechanics. Preference is given to candidates who have received their PhD within the last rear or two.

Postdoctoral members frequently collaborate with each other, with aculty members at the Institute or Princeton University, and with esearchers at other institutions.

Appointments are usually for no nore than two years and support is ypically full salary for postdoctorals and half salary for more senior persons. Women and minorities are incouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

# NATIONAL BIOLOGICAL STANDARDS BOARD Post-Doctoral Scientist

Division of Viral Products require a research scientist to join an active research group working on INTERFERONS. The studies will involve the production of interferon by human T-cel clones and hybridomas, and its characterization by molecular and immunogical methods. The post provides an opportunity for a young scientist to gain experience in a rapidly expanding field of medical importance.

Applicants should have recently completed a PhD degree in a relevant field.

The appointment is for three years and is supported by a grant from the Cancer Research Campaign.

Starting salary will be commensurate with age, qualifications and experience on the scale £6,070 to £9,750 plus £967 London Weighting.

Further details and application form from Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, Hampstead NW3 6RB. Ref no SG/295. Closing date 21/12/81.

# Re-advertisement NATIONAL BIOLOGICAL STANDARDS BOARD PHARMACOLOGIST/ PHYSIOLOGIST

Division of Hormones have an immediate vacancy for a post-doctoral pharmacologist/physiologist. The work currently involves research on the mechanism of action and methods of detection of pyrogens, and in the characterisation of small pharmacologically-active substances such as gut and neuroactive peptides.

Applicants should have a postdoctoral degree in pharmacology or physiology and have some experience of laboratory pharmacology research.

The salary payable is in accordance with qualifications, age and experience on the MRC Grade II (£7,037 pa — £10,717 pa inclusive).

For further details and an application form please contact the Personnel Officer, NIBSC, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232. Please quote ref no HO/049. Closing date 21st December 1981.

(9987)A

DEPARTMENT OF CHEMISTRY GRADUATE STUDIES

GRADUATE STUDIES IN CHEMISTRY 1982/83 Academic Year

Applications are invited from candidates with high academic records who wish to pursue further studies towards the MSc and PhD Degrees in Chemistry. Excellent research facilities are available in all areas of modern Chemical Science, ranging from Bio-Inorganic Chemistry to Chemical Physics. Teaching and research assistantships are available for all students in the program. The total minimum stipend is \$10,000 for MSc students, with higher amounts for PhD students and holders of graduate scholarships. Application forms and further particulars may be obtained from: James Trotter, Professor and Acting Head, Department of Chemistry The University of British Columbia, 2036 Main Mall, Vancouver, BC

(NW130)A

Canada V6T 1Y6.

# Smith Kline - RIT s.a.

a SmithKline companu

SMITH KLINE-RIT - RIXENSART, BELGIUM

# BACTERIAL VACCINE MANAGER

Applications are invited for a new position in the Animal Health R&D.

This collaborator will be responsible for: 
in vitro development of new bacterial vaccines; 
transfer of technology and know-how;

□ assisting the R&D Director in assessing opportunities for technology and know-how purchases.

Candidates should a Ph.D. degree and an industrial experience in the field of fermentation technology and biochemistry.

A working knowledge of French would be an asset.

Salary will be according to age, qualifications and experience.

The laboratories are located 15 km to the South East of Brussels in pleasant surroundings.

Please write with detailed c.v. to the attention of J.P. Dembour, Personnel Departement, rue du Tilleul 13, B-1320 GENVAL (Belgium).

(W520)A

# UNIVERSITY OF CAPE TOWN Senior Analytical Scientist in Archaeology

Applications are invited for the above post in the Archaeology Department, vacant as of January 1st, 1982.

The appointee will hold the rank of Lecturer in Archaeology with primary responsibility for building and developing a research laboratory for ratio mass spectrometry of carbon, oxygen, nitrogen, and hydrogen isotopes, utilising a VG Micro-mass 602E instrument. Further duties will include participation in the development of research and teaching programmes in science-based archaeology, with emphasis on mass spectrometry, but including other analytical techniques. It is expected that the appointee will be qualified at the Doctoral level (or equivalent) in a natural or physical science, have research interests relevant to archaeology, and have extensive experience with analytical instruments.

The post is a permanent staff position, subject to a 3-year probationary period, but a 3-year contract appointment could also be considered. Appointment will be made, according to qualifications and experience, on the salary scale R10 995 x 675 — R14 370 x 810 — R19 230 per annum. In addition a service bonus of nearly one month's salary is payable

Applicants should submit a full curriculum vitae, stating present salary, age, publications, relevant qualifications and experience, the date on which duty could be assumed and the names and addresses of three referees.

Further information should be obtained from the Head of the Archaeology Department and applications should be sent to the Registrar, (attention: Appointments Office), University of Cape Town, Rondebosch, 7700, South Africa, by whom applications (quoting ref no AC/11) must be received not later than February 15th, 1982 (late applications may be accepted).

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable from the Registra.

# SIMON FRASER UNIVERSITY

Burnaby, British Columbia, Canada

DEPARTMENT OF BIOLOGICAL SCIENCES

# POPULATION DYNAMICS

Applications are invited for a tenure-track position as Assistant Professor in Population Biology, with research interests in the dynamics of interspecific interactions (eg, predator-prey, parasite-host, pathogen-host). The successful applicant will be expected to develop a strong research programme and to teach at both the undergraduate and graduate level, including courses in the Department's Master of Pest Management Programme. Candidates must have a PhD degree, with experience in entomology and/or pest management. Preference will be given to candidates eligible for employment in Canada at the time of application.

The position is available from 1 September 1982. The current salary base for the Assistant Professor rank is \$25,000/year subject to ratification.

Applications should include curriculum vitae, a brief statement of research interests and objectives, and reprints of published research. Applicants should request a confidential assessment of their research and teaching ability from three referees, to be forwarded directly to: Dr K K Nair, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, BC, Canada V5A 1S6.

Deadline for receipt of applications is 31 December 1981, or until the position is filled. (NW119)A

# THE UNIVERSITY OF ALBERTA

Edmonton, Alberta Canada T6G 2E3

DEPARTMENT OF GEOLOGY

The Geology Department has one permanent faculty position available (subject to funding) July 1, 1982. We invite applications from qualified individuals for appointment at the Assistant or Associate Professor level in any of these areas: Geomor-phology, Mathematical Geology, Engineering Geology, Process Sedimentology and Structural Geology, Preference will be given to those applicants who demonstrate an ability to pursue a vigorous research program applying modern concepts and techniques in solving geological problems. The candidate is expected to teach an undergraduate course in quantitative geomorphology, course(s) in his or her speciality, including if qualified, geostatistics. The position also involves supervising Masters and PhD students. A PhD is required and salary is commensurate with education and experience. Canadian citizens and permanent residents will be given preference.

Interested applicants should sumbit a résumé, publications and names and addresses of three referees to Dr N W Rutter, Chairman, Department of Geology, University of Alberta, Edmonton, Alberta, Canada T6G 2E3. Closing date for applications is February 15, 1982. The University of Alberta is an equal opportunity an employer.

(NW127)A

# DEPARTMENT OF ZOOLOGY University of California, Davis ASSISTANT PROFESSOR

Applications are invited for a tenure-track position at the Assistant Professor level for September 1982. A strong, independent research program is expected; fields of particular interest include, but are not limited to, evolutionary biology, marine or behavioral ecology, and environmental physiology. Preference will be given to candidates able to teach invertebrate zoology at the upper-division level. The appointee may also teach a one — quarter course in introductory biology and will have the opportunity to develop courses and/or seminars in his/her area of expertise.

Persons wishing to apply should send a curriculum vitae, reprints of published work, a description of research program and future plans, a summary of teaching experience and capabilities including evaluations if available, and three letters of recommendation to:

Dr. Arthur M. Shapiro,

Dr. Arthur M. Shapiro,
Chairman, Search Committee,
Department of Zoology,
University of California,
Davis, CA 95616.
Final Date for receipt of applications is February 15, 1982.

Final Date for receipt of applications is *February 15, 1982*. The University of California is an equal opportunity/affirmative action employer. (NW101)A

# MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF MICROBIOLOGY CONTINUING LECTURER/SENIOR LECTURER

The Department conducts courses leading to BSc and BSc (Hons) at the Clayton Campus and to MBBS, BMed Sci at the Monash Medical School, Alfred Hospital. The successful applicant would be expected to teach in appropriate areas of these courses and to supervise graduate students for MSc and PhD. Activities of the Department include molecular biology, genetics, virology, microbial biochemistry, medical microbiology, pathogenesis of infections and immunology. Applicants should possess either MD or FRCPA, or PhD or equivalent qualifications. Experience in medical microbiology or related fields an advantage. Excellent research facilities available and opportunities exist for a suitable appointee to participate in the diagnostic, clinical and research work of the teaching hospital of the University, including the Alfred Hospital and Fairfield Hospital for Infectious Diseases. Annual salary: Lecturer \$A19,821 — \$A26,036; Senior Lecturer \$A26,593 — \$A30,995; Medically qualified Lecturer \$A23,151 — \$A29,367 or Senior Lecturer \$A29,923 — \$A34,325. Superannuation, travel and removal expenses, Outside Studies Programmes and temporary housing assistance. Enquiries about the position may be addressed to Staffing Committee, Department of Microbiology in the University

Applications including Ref No 30912, curriculum vitae and 3 referees to the Registrar, Monash University, Clayton, Vic. 3168, Australia, with a copy to the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, as soon as possible and not later than 5/2/82. Conditions of appointment can be obtained from the Association. (9994)A

STATENS SERUMINSTITUT (Copenhagen)

# DEPUTY HEAD OF DEPARTMENT

A position is available in the Enterovirus Department from 1st February 1982 or as agreed upon. Responsibilities will include routine functions and basic and applied research. Routine functions comprise the preparation of cell cultures for the production of inactivated polio vaccine (IPV), culture and inactivation of polio virus, carrying out all control tests which are required during production and before release of IPV as an independent vaccine or as a partial product of Di-Te-Pol vaccine. The work also includes testing and evaluation of other virus vaccines.

The department also functions in an advisory capacity in questions relating to vaccines and vaccination and postgraduate education. In the future this section will be responsible, in collaboration with other production departments, for the entire production and control of vaccines at the Institute and will probably be incorporated with one or severel departments in a production section, at a later date.

Candidates should be conversant with production and control of biological products. Experience in microbiological, biochemical and/or immunological methods would be an advantage.

The ideal candidate is a person of proven research ability with a flair for leadership.

The position is permanent, salary 271.500 Danish kroner. The work will be carried out at Statens Seruminstitut, but the appointment is under the Ministry of the Interior.

Applications should be addressed to Her Majesty the Queen and five copies should be sent to the Directors, Statens Seruminstitut, Amager Boulevard 80, DK-2300 Copenhagen S, by 4pm 8th January 1982.

(W522)A

# ©SIRO AUSTRALIA Biological Systems Modeller

\$A19,662 — \$A28,564 pa
Division of Computing Research
Canberra Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,500 employees — 2,700 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

A scientist with biological and computer modelling experience is required to work in the Division's simulation section which is concerned with modelling complex systems which may have physical, biological and economic aspects. Projects of biological interest include: developmental biology, biotechnology, insect and parasite control, plant and animal growth and aquatic and terrestrial ecosystems. Such projects are carried out in close collaboration with staff of other Divisions of CSIRO.

The section is multi-disciplinary, with expertise in computing, systems theory and the physical sciences and considerable experience in biological modelling. Research interests of the simulation section also include programming, numerical methods and all aspects of the methodology of modelling.

The Division's research staff are located in close proximity to several of the major biological Divisions of CSIRO and to the Research Schools of Sydney University and the Australian National University. The appointee will have opportunities for close contact with biological scientists and modelling groups throughout Australia.

The Divison has branches in most Australian cities and provides to other Divisions a high-level consulting service covering most phases of advanced computer use. Fields in which other sections of the Division are working include operating systems, data-base management, image processing, graphics, micro-electronics and numerical taxonomy.

The Division has a Control Data Cyber 76 computer as the main component of a very large multi host network known as CSIRONET. This provides a powerful tool for research and development, and enables scientists in CSIRO laboratories throughout Australia to use both central and distributed facilities for either batch or interactive computing. It also allows sharing of data and cooperative development of programs.

**Duties:** (1) Within a group of diverse computing and modelling specialists, to collaborate extensively with biological groups applying simulation modelling to practical problems.

(2) To develop further the computing and theoretical techniques needed for the simulation and dynamic analysis of biological and other complex systems.

Qualifications: A PhD degree in an appropriate biological field or equivalent qualifications together with demonstrable research ability. Considerable computational skill and ability to develop computer models is essential.

Tenure: 3 years with superannuation.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No A1895, should reach: The Chief, Division of Computing Research, CSIRO, PO Box 1800, CANBERRA CITY, ACT 2601 AUSTRALIA by 1 January 1982.

# AUTONOMIC NEUROPHYSIOLOGIST RESEARCH ASSOCIATE

to serve as co-investigator of NASA-funded experiment to be conducted on astronauts in space shuttle. Applicant must have doctoral degree and be an independent, established scientist with a broad understanding of autonomic cardiovascular physiology, and peculiar interest and skill in electrophysiology and/or central autonomic neuroanatomy.

Send curriculum vitae and salary requirements to Dr Dwain L. Eckberg, Cardiovascular Physiology, V.A.Medical Center, Richmond, Virginia 23249. (NW122)A

# **Jirector**

# **MRC Trauma Unit: Manchester University**

The Medical Research Council invites applications for the post of full-time Director of the MRC Trauma Unit, Manchester. The present Director, Professor H B Stoner, retires in September 1984: the successful candidate would be encouraged, subject to mutually acceptable arrangements, to take up appointment earlier, as Director-designate.

The present work of the Unit aims to lead to improvements in the care of the injured. The research programmes are a combination of clinical, laboratory and experimental studies. The Council wishes the emphasis on research in trauma to be maintained; it will however review the title and programme of the Unit in the light of the research interests of the new Director.

The University of Manchester will consider conferring on a suitable appointee an honorary Professorship in

The University of Manchester will consider conferring on a suitable appointee an honorary Professorship in an appropriate discipline.

The Unit is housed in the Medical School (Stopford Building) of the University of Manchester and has clinical laboratory accommodation, with facilities for the study of acutely injured patients, at the Hope Hospital, Salford, where a new NHS Accident and Emergency Department and an Intensive Care Unit (10 beds) will be commissioned in 1984.

rent and an intensive Care unit (10 beds) will be commissioned in 1984.

The eventual scale and composition of the staffing of the Unit will be a matter for discussion between the new Director and the Council.

Applicants should be medically qualified and eli-

Applicants should be medically qualified and eligible for honorary consultant status in an appropriate speciality. It is expected that the person appointed would be of high scientific standing with an established reputation as an original scientific investigator and a capacity to direct both the clinical and the basic aspects of the Unit's programme. It is considered essential for the success of the venture that the present high level of clinical collaboration with the NHS staff at the Hope Hospital should be maintained and an ability to foster this relationship will be a key quality sought in the successful applicant.

An honorary clinical contract with the Salford AHA (1) (6/11ths) at consultant level in an appropriate speciality will be offered to the successful candidate. The appointment carries a salary on the MRC clinical scale, which is equivalent to NHS consultant grade.

Further information may be obtained from Mr R

Further information may be obtained from Mr R Bush, MRC Headquariers Office, 20 Park Crescent, London W1N 4AL Tel 01-636 5422

Ext 353. Applications, including the names of three referees, should be submitted to the Secretary of the Council at the same address, not later than 22 Medical Research Council January 1982.

# AGRICULTURAL RESEARCH COUNCIL POULTRY RESEARCH CENTRE Roslin, Midlothian EH25 9PS **SCIENTIFIC OFFICER**

A Scientific Officer is required in the Ethology Department to assist with research on poultry behaviour and welfare. This research project seeks to identify and correlate behavioural and physiological parameters which may be indices of stress. The successful candidate will be expected to participate fully in all aspects of the work. Duties will include implanting telemetry devices, observing and recording behaviour patters of birds, collaborating over data collection and sorting, using a PDP11 computer, day-to-day supervision of experimental birds and drafting reports on experiments and papers for publication. The Officer will report directly to the Head of the Ethology Department and be responsible for supervising an A.S.O.

Qualifications: A pass degree (or equivalent) in Biology, Zoology, Psychology, Agricultural Science, or related discipline. A good general knowledge of animal behaviour and physiology is required. Some knowledge of statistics and computer programming would be an advantage.

Salary: In scale £5,176 - £6,964. Non-contributory pension scheme. 20 days annual leave.

Application forms are available from Mrs Hunter, Assistant Secretary, at the above address. Completed forms must be returned to her by the 11th December 1981.

# **CSIRO**

# **AUSTRALIA**

# **Assistant Chief** (Geneticist)

\$A29,638 - \$A38,921

# **Division of Animal Production Prospect, New South Wales**

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximatley 7,500 employees 2,700 of whom are research and professional scientists - located in divisions and sections throughout Australia.

Field: Genetics

The Division of Animal Production, with Headquarters at Prospect, near Sydney, New South Wales, conducts research aimed at understanding the genetic, nutritional and physiological basis of animal functions with the aim of improving the efficiency of livestock

Duties: The appointee will assist the Chief of the Division in the guidance and coordination of a research group with interests ranging from basic research in molecular and developmental genetics to animal breeding in poultry, sheep and cattle. Future basic research in the genetics program will be broadly directed at the application of new genetic technologies to animal improvement, and the successful applicant will be expected to provide scientific leadership in this area. In addition, the appointee will liaise with scientists in the Division who are studying skin biology, nutrition and reproduction, and to aid in the development of inter-disciplinary research programs to improve animal production.

Qualifications: Applicants should have a PhD degree or equivalent, a substantial record of research achievement in genetics and the ability to lead a research team. An interest in the application of molecular and cellular biology and quantitative genetics to improving animal production is essential.

Tenure: This is an indefinite appointment which carries Australian Government Superannuation benefits. However, the role of Assistant Chief is offered for an expected term of seven years.

Note: An outstanding applicant may be offered appointment at a higher level

Applications: Stating full personal and professional details, the name of at least two referees, and quoting reference No A0905 should reach: The Chief, Division of Animal Production, CSIRO BLACKTOWN, NSW 2148 AUSTRALIA by 1 January 1981. (006)A

#### MONASH UNIVERSITY Melbourne, Australia

DEPARTMENT OF MATHEMATICS FIXED TERM (5 YEARS) LECTURER IN APPLIED MATHEMATICS

Research groups are active in astrophysics and geophysical fluid dynamics, and preference will be given to applicants whose research relates to the gfd group involving basic fluid dynamics and its applications to dynamical meteorology and oceanography, and geophysical data analysis.

Salary: \$A19,821 to \$A26,037 pa. Superannuation, travel and removal expenses, temporary housing assistance and repatriation.

Enquiries to Professor BR Morton Enquiries to Professor B R Morton in the University. # MEMORIAL UNIVERSITY OF NEW FOUNDLAND DEPARTMENT OF BIOCHEMISTRY PROSPECTIVE POSTDOCTORAL TRAINEES

graduate students and research fellows are encouraged to apply for research positions in the area of environmental and marine biochemistry, antifreeze proteins, membrane glycoproteins, intermediary metabolism, physical chemistry of lipids and proteins, experimental and community nutrition, microbiology, food sciences, food processing and food engineering. Grant-funded research in these areas is conducted in well-equipped laboratories by highly motivated research faculty. Salaries of postdoctoral and research fellows, other benefits and starting dates are negotiable. Fellowships of graduate students may be supplemented from grants and teaching assistantships.

Apply with vitae and two letters of recommendation to Dr S Mookerjea, Head, Department of Biochemistry, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X7, Canada. (9979)A

#### **CELL BIOLOGIST**

The CV Whitney Laboratory, a research center of the University of Florida, invites applications for a full time, tenure-earning research position at the assistant or associate professor level. The successful applicant will be expected to develop a strong independent research program and to interact with existing projects in nuerophisiology, neurochemistry, cellular immunology, biochemistry and membrane transport. All applicants with good ideas on fundamental questions will be seriously considered, but preference be given to applicants with training or experience in immunology who would be interested in taking advantage of marine organisms to study problems in neurobiology, endocrinology, comparative im-munology, cell-cell interaction or fertilization.

Send letter stating current and future research interests, curriculum vitae and names of four references by December 31, 1981 to: Search Committee, CV Whitney Laboratory, University of Florida, Rt 1, Box 121, St Augustine, FL 32084. An Equal Opportunity/Affirmative Action Employer. (NW128)A

Canada Service

Research Scientists

Salary: \$23,225 - \$43,200 Ref. No.: 81-NCRSO-DFO-7, 8 and 9

Department of Fisheries and Oceans Ocean Science and Surveys Dartmouth, Nova Scotia

The Bedford Institute of Oceanography, Dartmouth, Nova Scotia, requires two scientists to participate in marine environmental quality research and a third scientist to conduct research into the ecology and life history of fish.

#### MARINE PHYSIOLOGICAL BIOCHEMIST

#### 81-NCRSO-DFO-7

Research experience in the study of biochemical and physiological pathways and reservoirs of metal or radio-nuclide accumulation in marine biota is required for this position. Experience is also required in the handling and determination of radioisotopic tracers and ocean sampling equipment.

#### **BENTHIC MICROBIAL ECOLOGIST**

#### 81-NCRSO-DFO-8

For this position, research experience in the study of benthic microbial ecology is required. Experience in the handling and determination of radioisotopic tracers and conducting in situ experiments at sea is also required.

# FISHERIES ECOLOGIST

#### 81-NCRSO-DFO-9

To successfully meet the requirements of this position, experience is required in the planning and directing of laboratory and field programs on the ecology of aquatic production. Also, a demonstrated capacity in statistical and mathematical analysis of ecological systems is required.

#### Qualifications

All three positions require a doctorate or a lesser degree with research experience and productivity equivalent to that of a doctorate.

#### Language requirements

Knowledge of the English language is essential.

Clearance Nos.: 111-211-006

111-211-005

# Greenford, Middx.

c. £10,000-£13,000

required to work on the production of secondary metabolites from fungi, natural and genetically-engineered bacteria and Streptomycetes. We have recently completed a new plant which has shake-flask, 5, 50 and 500 litre fermenters and is fully instrumented and data logged, with extensive on-line and off-line data-handling facilities, including graphics. Your responsibility is to establish the production of new natural and engineered fermentation products using batch and continuous culture. The Biotechnology Department is also concerned with enzymology and both plant and animal cell culture.

You will have several years' post-doctoral experience in microbial physiology and will view our vacancy as a unique opportunity to apply the most modern techniques, in association with genetic engineers, to making a broad spectrum of fermentation products.

The Company offers excellent conditions of employment, including a non-contributory pension scheme, bonus schemes and an active sports and social club. Relocation assistance will be given if appropriate.

Please write or telephone for an application form to: Miss E. M. Butler, Personnel Department, Glaxo Group Research Ltd., Greenford Road, Greenford, Middlesex UB6 0HE. Tel: 01-422 3434, ext. 2707, quoting ref. AQ.399.

# CSIRO AUSTRALIA **Biochemist** (Research Fellow)

\$A19,662 - \$A28,564 pa **Division of Plant Industry** Canberra Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,500 employees - 2,700 of whom are research and professional scientists - located in divisions and sections throughout

General: The Division conducts pure and applied research in genetics, plant breeding, genetic resources, biochemistry, microbiology, plant nutrition, ecology, crop adaptation, soil fertility and plant introduction.

The position is in the Biochemistry Section where current research includes studies on chloroplasts membranes, protein and nucleic acid metabolism in chloroplasts, photosynthetic carbon matabolism, the biochemistry and physiology of seed proteins, and haemoproteins involved in nitrogen fixation.

Duties: To undertake research on the biochemistry of C4 photosynthesis. This will be part of a project which presently includes studies on enzyme regulation, metabolism of isolated cells and organelles, and metabolite transport processes

Qualifications: Applicants should have a PhD degree or equivalent in an appropriate field. Previous experience in the field of photosynthesis biochemistry would be an advantage

Tenure: The position is available for three years with the possibility of extension up to two years beyond this period if mutually desired. Superannuation benefits available.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No A4735 should reach: The Chief, Division of Plant Industry, CSIRO, PO Box 1600, CANBERRA CITY, ACT 2601, AUSTRALIA by 1 January 1982.

# **ROYAL FREE HOSPITAL** SCHOOL OF MEDICINE (University of London)

DEPARTMENT OF BIOCHEMISTRY

#### AND CHEMISTRY **POSTDOCTORAL** RESEARCH ASSISTANT

Physicist or physical chemist required to join research group working on dynamics of biomembranes. Experience of optical methods and laser techniques would be an advantage. Post is tenable for 2 years, supported by the SERC.

Salary on Range 1A: £7,037 £11,542 (inclusive). Applications (cv and names and addresses of two referees) should be sent to the School Secretary, RFHSM, Rowland Hill Street, London NW3 2PF as soon as possible. Please quote ref: SERC/B.

### MANCHESTER AREA **HEALTH AUTHORITY** (TEACHING)

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE

#### RESEARCH STUDENT

Applications are invited from graduates with a good honours degree in a biological subject for a three year research studentship concerned with neuroectodermal tumours of children.

The project will involve im-munological and electron microscopic techniques.

Applications including curriculum vitae and the names of two referees should be sent to the Hospital Administrator, Christie Hospital & Holt Radium Institute, Wilmslow Road, Manchester 20. (9974)A

#### POST-DOCTORAL FELLOW

Post-Doctoral position in Virology to study the genetics of influenza viruses. Project includes 1) molecular cloning of influenza virus genes, sequencing and expression of cloned genes, and 2) analysis of the biological function of individual genes, pathogenicity factors, analysis of epidemiologically important influenza virus strains. Position now available. Please submit cv to Dr Peter Palese. The Mount Sinai School of Medicine, One Gustave L Levy Place, New York, NY 10029. An Equal Opportunity employer.
(NW123)A

### THE NATIONAL HOSPITALS FOR NERVOUS DISEASES Oueen Square,

# London WC1N 3BG RESEARCH ASSISTANT OR SRN

For six months starting from 1st January 1982 to assist with Physiological studies on patients with neurological disorders. You must have a sympathetic approach to patients and previous experience in the neurological field would be useful although not essential. Five-day week (Monday to Friday).

Salary Scale is dependent on experience and educational qualifications.

Application forms obtainable from and returnable to: The at the above Personnel officer address, Tel: 01-837 3611 ext 65.

Closing Date 16th December 1981. (9975)A

# Synthetic Organic and Physical Organic Chemists

We are planning the recruitment of top quality organic chemists for the period 1982-1984, and require innovative and resourceful scientists who will play an important role in drug discovery, as part of a multidisciplinary team. Current projects cover most major disease areas and provide the organic chemist with the challenge of design and synthesis of drug molecules and of understanding the way they interact with biological systems.

We are interested in making contact with candidates in the following categories:

- Synthetic organic and physical organic chemists under 30 with a Ph.D. and post doctoral experience who are seeking a position in 1982.
- Synthetic organic and physical organic chemists under 30 who have recently gained or are completing their Ph.Ds in

1982 and who intend to undertake postdoctoral research before seeking employment in 1983-84.

The Division's research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Salaries and conditions of employment will reflect the importance of these posts and relocation assistance will be provided.

Applications in writing including a detailed C.V. and quoting Ref. No. I.C.P. 663 should be addressed to:

Mr. R. Yates, Personnel Officer, Imperial Chemical Industries P.L.C. Pharmaceuticals Division, Mereside Research Laboratories, Alderley Park, Macclesfield, Cheshire, SK10 4TG.

# JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

### RESIDENT SCIENTIST (TOXICOLOGY)

Indonesia

A co-operative development project is being undertaken between the Animal Diseases Research Institute, Bogor, Indonesia (Balai Penelitian Penyakit Hewan) and James Cook University, supported by the Australian Development Assistance Burean.

The project group will develop training programs for Indonesian graduate and technical staff engaged in diagnostic and research duties within the Institute. It is expected that collaborative work will evolve with other institutes in the Bogor area and with regional diagnostic laboratories throughout Indonesia.

Applications are sought for the position of Resident Scientist (Toxicology). The appointee will lead the toxicology section within the Institute and will have responsibility for the training of counterpart Indonesian staff in field and laboratory methods of identifying toxic materials in plants and foodstuffs. In addition, the appointee will be expected to take part in extension activities and develop applied research programs.

Applicants must have a higher degree and substantial experience in research and training, especially at the graduate level. Extensive experience is required in chemical and/or pathological aspects of toxicology in animals, preferably under field conditions. Previous work with mycotoxins would be an advantage. An appreciation of areas of priority and appropriate technology in a developing country is essential and previous work in the tropics is desirable.

The appointment will initially be for two years. The appointee will be expected to take up duty in Indonesia in June 1982 or as soon as possible thereafter and this will be preceded by a 2-3 month period of induction and language training in Townsville, Queensland.

Appointment will be within the salary ranges \$A19821 — \$A26037 per annum or \$A26593 — \$A30995 per annum with the commencing salary being determined on the basis of qualifications and experience. Overseas allowances, assistance with children's educational expenses and assistance with removal and travel expenses will apply as appropriate.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 29 January 1982. (9991)A

POSTDOCTORAL Research Position available to study the role of folyl polyglutamates in tumor cell proliferation. Experience in enzymology and protein chemistry helpful. Send curriculum vitae and names of three references to: Dr D G Priest, Department of Biochemistry, Medical University of South Carolina, 171 Ashley Avenue, Charleston, SC 29425. (NW124)A

## UNIVERSITY COLLEGE GALWAY, IRELAND RESEARCH ASSISTANT

Applications are invited from Graduates in Physiology, Biochemistry and allied subjects to study the extra-renal production of glutamine in metabolic acidosis. Experience in substrate and enzyme assays is desirable, but not essential. The research is supported by the

Medical Research Council of Ireland.
Applications including Curriculum
Vitae and referees should be sent to:
Professor D J O'Donovan,
Physiology Department,
University College, Galway,
Ireland, not later than 20 December,
1981. (002)A

# UNIVERSITY OF ABERDEEN DEPARTMENT OF BOTANY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for this NERC-funded post tenable for 3 years from January 1982 to work with Dr I Alexander on patterns of release and transformation of nitrogen in forest humus and its utilisation by ectomycorrhizas. Applicants should have relevant experience in one or more of the following fields; root development, ectomycorrhizas, estimation of fungal biomass or activity, lysimetry, nitrogen transformations in soil.

Salary within Scale 1A as appropriate.

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by 23 December 1981. (9985)A

# INSTITUTE OF CANCER RESEARCH

CHEMICAL CARCINOGENESIS DIVISION

Applications are invited for a

# POSTDOCTORAL RESEARCH POST

at the Institute's laboratories at Pollards Wood, near Amersham, Bucks. The post, funded by the MRC/CRC, is available immediately to work with a group concerned with the molecular basis of mutations induced by chemical carcinogens.

Applicants should preferably have research experience in molecular biology, recombinant DNA technology or a related field. Starting salary in the range £6,880 to £8,515 p.a.

A brief CV (in duplicate) containing an indication of postgraduate research experience should be sent, with the names of two referees, to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref: 300/G/11.

Informal enquiries may be made to Dr P Brookes, telephone 02404-2326. (9993)A

# The University of Arizona Seeks a Dean of the Faculty of Science

The University of Arizona is creating a new College of Arts and Sciences to be composed of the Faculties of Fine Arts, Humanities, Sciences, Social and Behavioral Sciences. The Faculty of Sciences will consist of about twelve departments including mathematics, the physical, and biological sciences in a growing series of a major programs on our campus. The administration recognizes the scientific achievements of its faculty and now desires to enhance both the cohesion and leadership in these disciplines by means of the new organization.

The University is seeking candidates for the Dean of Faculty of Science who have the highest qualifications, both in academic and administrative accomplishments. The appointment will also include a professorship with tenure. The Dean will be responsible for academic, administrative and budgetary activities within his faculty and will report to the Provost of the College of Arts and Sciences. All inquiries, applications, and nominations should be sent to the Office of the Executive Vice President no later than February 1, 1982

A. B. Weaver, Executive Vice President, University of Arizona, Administration 512, Tucson, Arizona 85721.

Equal Opportunity/Affirmative Action Employer. (NW108)A

#### MEDICA **RESEARCH COUNCIL** MAMMALIAN **DEVELOPMENT UNIT**

Applications are invited for a

#### SHORT-TERM NON-CLINICAL SCIENTIFIC POST

in this MRC unit, tenable for 3 to 5 years, to study early mammalian development, Candidates of immediately post-doctoral or equivalent status wil be preferred; molecular or bio-chemical experience will be particularly welcome.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from The Secretary MRC Mammalian Development Unit Wolfson House, 4 Stephenson Way London NW1 2HE, with whom appli cations, including a full CV and the names of two professional referees should be lodged by December 31 1981. (9920)A

UNIVERSITY OF DUBLIN **Trinity College** 

# **LECTURER** IN BOTANY

Applications are invited for the above post in the Department of Botany, Trinity College, Dublin. The post will be tenable from 1st October 1982.

Preference will be given to applicants with interests in electron microscopy and plant physiology. Salary Scale: £7,006 — £14,557 per annum.

Appointment will be made within the salary range £7,006 - £8,994 p.a.

Application forms and further particulars may be obtained from:

The Establishment Officer, Staff Office. Trinity College, Dublin 2.

Telephone 772941 ext 1775.

The closing date for receipt of applications will be Monday, 21st (9976)A December, 1981.

# MICROBIOLOGY/ **IMMUNOCHEMISTRY**

A Research Fellow is required to join a team investigating the microbiological aspects of dental caries at the Royal College of Surgeons laboratories in Downe, near Orpington, Kent. Much of the work is concerned with the biochemical and immunochemical characterisation of Streptococcus mutans and a wide range of bacteriological, biochemical and immunological techniques is in use. The position would suit a recent PhD in microbiology/biochemistry or a good honours graduate with relevant experience.

The initial appointment will be for 3 years. Salary on the University of London Research and Analogous Staff scale 1B (£6,252 to £8,667) according to experience.

Please apply by sending curriculum vitae to the Personnel Officer, Royal College of Surgeons of England, 35-43 Lincoln's Inn Fields, London WC2A

#### **AMGUEDDFA** GENEDLAETHOL CYMRU NATIONAL MUSEUM OF WALES

DEPARTMENT OF GEOLOGY

Applications are invited for the post of **ASSISTANT** 

(MUSEUM GROUP F)

in the Department of Geology

Applicants should possess a degree in Geology, preferably with a particular interest in mineralogy/petrology; the post will involve a wide range of museological/technical duties

The person appointed will be on salary scale £5,589 - £7,682 with contributory pension rights.

Annual leave entitlement 20 days plus 11 privilege days.

Further particulars of the post may be obtained from: The Secretary, National Museum of Wales, Cathays Park, Cardiff CF1 3NP to whom applications should be submitted not than Friday, January 15t (9983)A 15th,

# CSIRO

# **AUSTRALIA**

# Division of Soils Adelaide SA

# **Chief of Division**

Applications are invited for the position of Chief, Division of Soils, from scientists who have an outstanding record of personal research achievements and leadership in soil science, or other appropriate fields. The position will become vacant in December, 1982, on the expiry of the term of appointment of Dr. A.E. Martin as Chief. If able to join the Division before this date, the succesful applicant will be appointed as Chief Designate and have the opportunity to commence planning the future course of the Division.

CSIRO is Australia's largest and most comprehensive research

organization, having approximately 7,500 employees of whom 2,700 are research and professional scientists. Its broad charter covers research into problems of primary and secondary industries, and also such fields of community interest as human nutrition, the environment and the development and use of natural resources. The Organization's research activities are grouped into five Institutes, and the Division of Soils is one of the Divisions in the Institute of Biological Resources. The other constituent Divisions of the Institute are Entomology, Forest Research Horticultural Research, Irrigation Research, Land Resources Management, Land Use Research, Plant Industry, Tropical Crops and Pastures and Wildlife Research.

The Division of Soils has its headquarters at Adelaide, and also operates research laboratories at Brisbane and Townsville (Qld), Canberra (ACT) and Hobart (TAS). The total staff of the Division is 205, which includes 100 professional scientists.

The objectives of the Division are to conduct research into soil science, including the physics, chemistry and biology of soils, together with the integrative disciplines of pedology and geomorphology and to develop the principles for its application in both dryland and irrigated agriculture, forestry, hydrology, engineering and conservation.

The Chief of Division is responsible to the Institute Director for the leadership, development, scientific direction and integration of the Division's research programs, and is encouraged to promote active collaboration with other Divisions, industry and research bodies working in associated areas.

The salary for the position is negotiable, but will not be less than

\$A43,988 per annum

Appointment to CSIRO is for an indefinite period and carries
Commonwealth Government superannuation privileges, subject to normal conditions. The position of Chief is offered for a negotiable term of the order of seven years, with subsequent options for a further term, if mutually desired, or for a senior position in the

Organization.
The Executive of CSIRO has appointed a Search Committee to seek suitable candidates for this position, and the Chairman of the Committee is Mr. M.V. Tracey, OA, FTS, Director of the Institute of Biological Resources. Mr. Tracey would be pleased to discuss the position with potential applicants and to recieve advice concerning this appointment from people with a particular interest in it. He may be contacted at the address below.

Applications, stating full personal and professional details, and quoting reference No. A5187, should be submitted to: Mr. M.V. Tracey, OA, FTS, Director, Institute of Biological Resources, CSIRO, PO Box 225, Dickson, ACT 2602, Australia by 1 January 1982.

Opportunities in the Central Laser Division for

# A Laser Scientist and a Theoretical Physicist

vacancy exists for a Laser Scientist in the Glass Laser Group of the Laser Division. The Laser is used for research by University of the Laser Division. The Laser is used for research by Oniversity and other groups primarily for the study of laser-plasma interactions and laser driven compression by providing seven beam lines at two wavelengths, a range of pulse durations and maximum peak power approaching one Tw per beam. Applicants should hold a good honours degree and have several years experience in the use of high power lasers in plasma physics or a similar research field. A thorough knowledge of laser physics and experience in the operation of high power glass lasers is essential. The successful applicant must be willing to work outside normal laboratory hours on a shift basis. Please quote ref. VN 995 in all replies.

There is also a vacancy for a Theoretical Physicist in the Theory and Computation Group of the Laser Division, Rutherford Appleton Laboratory. The group is involved in basic research and the interpretation of experimental data on laser-plasma interactions and laser compression, in laser optical component design interactions and laser compression, in laser optical component design and in the development of computer codes for this work. Most of the group's work is in collaboration with University teams in similar fields. Applicants should hold a good honours degree and have several years experience in at least one of the topics listed above, together with some experience in numerical techniques. Please quote ref. VN 996 in all replies.

The successful applicants will be appointed to the Higher Scientific Officer Scale of £6,530 to £8,589.

Application forms can be obtained from the Recruitment Office, Personnel Group on Abingdon (0235) 21900, Ext. 510. Alternatively, write to her quoting the relevant reference number, to Rutherford Appleton Laboratory, Chilton, Didcot, Oxon. OX11 0QX.

Closing date for applications: 16th December 1981.

#### Weed Research Organization

To develop a programme to study the effect on phytotoxicity of the physical form in which a herbicide reaches the plants. An important aspect will be activity following transfer in the vapour phase. A biophysical approach to the problem is required.

Candidates must possess a first or upper second class honours degree in a biological science, chemistry or physics with at least two years relevant post-qualifying experience for appointment to the higher grade. Salary on Civil Service scales.

For further particulars and application form write to the Secretary, Weed Research Organisation, Begbrooke Hill, Yarnton, Oxford OX5 1PF quoting 15/81. Completed applications are to be returned by 24th December 1981.

## STATENS SERUMINSTITUT (Copenhagen)

### **DEPUTY HEAD** OF DEPARTMENT

A position is available in the Vaccine Department from 1st February 1982 or as agreed upon. Responsibilities will include routine functions, and basic and applied research. The Department produces bacterial vaccines, purifies immunoglobulins, completes other products and purchases vaccines and immunoglobulins from abroad.

The Department, which is impliine Department, which is implicated in an advisory capacity in questions relating to vaccines and vaccination and in postgraduate education, is a WHO Collaborating Centre for Research and Reference Services for Immunological Biological Products and WHO Laboratory for Biological Standards. In the future the Department will be In the future the Department will be responsible, in collaboration with the other production departments, for the entire production and control of vaccines and will probably be incorporated with one or several departments in a production section, at a later date.

Candidates should be conversant with production and control of biological products. Experience in microbiological, biochemical and/or immunological methods would be an advantage.

The ideal candidate is a person of roven research ability with a flair for leadership.

The position is permanent, salary 271.500 Danish kroner. The work will be carried out at Statens Seruminstitut, but the appointment is under the Ministry of the Interior.

Applications should be addressed to Her Majesty the Queen and five copies should be sent to the Directors, Statens Seruminstitut, Amager Boulevard 80, DK-2300 Copenhagen S, by 4 pm 8th January 1982

(W523)A

### RESEARCH APPOINTMENT Applications are invited from ORGANIC CHEMISTS OR **BIOCHEMISTS**

to join a group working on the structural aspects of protein-nucleic acid interactions. The project involves the synthesis and examination of model systems by X-ray crystallography and other physical methods. While previous direct experience in this field is not required, candidates should have good experimental ability. Postdoctoral qualifications helpful but not essential.

The post is supported by a long term MRC grant. Initial appointment term MRC grant. Initial appointment for two years with possibility of renewal. Salary dependent on age and qualifications. Please apply in writing, including cv and names of two referees to Dr Olga Kennard, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW. (9995)A

A CELL Biologist is required in the Molecular Pharmacology Department for a project concerned with chemically induced neoplastic transformation and mutation in mammalian cells in culture. Experience of tissue-culture methodology and other cell biological procedures would be advantageous. Knowledge of German is not necessary. The salary is approximately DM 4,000 BAT IIa). The appointment is to begin as soon as possible. Applications to: Professor Dr Oesch, Department of Pharmacology, University of Mainz, Obere Zahlbacher Strasse 67, 6500 Mainz, West-Germany. (W514)A

#### **MOLECULAR BIOLOGIST/** BIOTECHNOLOGY

NORDISK GENTOFTE, Copenhagen, Denmark is currently expanding its research and development programme in the field of bio-technology. Applications are invited from scientific personnel with interest, qualifications, and experience within

- DNA technology
- cloning of eukaryotic genes
- expression of cloned genes in various hosts

fermentation technology. NORDISK GENTOFTE manufactures and markets insulins, plasma products, human growth hormone etc. and makes up the independent foundation NORDISK INSULINLABORATORIUM together with HAGEDORN RESEARCH LABORATORY (Basic research into diabetes) and STENO MEMORIAL HOSPITAL (research and treatment

of diabetes).
NORDISK GENTOFTE is conveniently situated in the northern part of Copenhagen.

For further information please contact Dr. H. H. Dahl (telephone:

(45) 1 680168 ext 432).

Applications with curriculum vitae should be sent to: NORDISK GENTOFTE, Niels Steensensvej 1, DK-2829 Gentofte, Denmark

#### **GEOPHYSICAL FLUID** DYNAMICIST/PHYSICAL **OCEANOGRAPHER**

Applications are solicited for a junior faculty position in ocean physics or dynamics to begin in the academic year 1982-83. Areas of interest to the Department include analytical, numerical and laboratory modeling of physical processes and phenomena in the sea.

Yale University is an equal opportunity/affirmative action employer and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications, and the names of three or more referees should be sent by 31 December 1981 to: Robert B Gordon, Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven, CT06511. (NW133)A

### **GENETICS LABORATORY** DEPARTMENT OF BIOCHEMISTRY POST-DOCTORAL

RESEARCH ASSISTANT **GRADE IA** (Ref: G/R/46)

A position is available for two years to work on human complement variants using electrophoretic techniques and serological techniques. Consideration will be given to Post-Graduates with relevant experience. Part time work might be considered for exceptional applicants.

Salary on the scale £6,070 pa -£7,290 pa.

Applications, including a full cv and the names and addresses of two referees, should be sent as soon as possible to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU.

(9996)A

#### THE MATHILDA AND TERENCE KENNEDY INSTITUTE OF RHEUMATOLOGY

#### POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a Post-Doctoral Research Assistant in the Division of Biochemistry (Head, Dr Helen Muir, FRS). The successful applicant will be required to develop methods for the production of mono-clonal antibodies to lysosomal enzymes as part of a project involving an investigation into the ability of different types of cell to exchange lysosomal enzymes

Previous experience in immunological and/or cell culture techniques is required. The position is funded for 3 years starting salary up to £7,847 including London Weighting on Range IA of the Research Staff scales of London University.

Applications. including curriculum vitae and the names of two referees, should be addressed to: The General Secretary, The Mathilda and Terence Kennedy Institute of Rheumatology, 6 Bute Gardens, Hammersmith, London W67DW.

# **UNIVERSITY OF CAPE TOWN ASSOCIATE PROFESSOR OR** SENIOR LECTURER IN GENETICS

Applications are invited for the above post in the Department of Biochemistry. Appointment, according to qualifications and experience, will be made on the salary scale:

Senior Lecturer: R14,370 × 810-R20,850 pa. Associate Professor: R18.420 × 810-R20,850 × 900-R22,650 pa. In addition a service bonus of nearly one month's salary is payable annually.

Candidates should have strong research interest in eucaryotic molecular genetics and experience in recombinant DNA technology and assume duties during the first half of 1982. Candidates should state for which post they wish to be considered.

The post may also be filled at the request of the applicant on a contract basis for 2-3 years with either the possibility of renewal or conversion into a tenured post.

Applicants should submit curriculum vitae, stating present salary, research interest and publications, when available if appointed, and the names and addresses of three referees.

Further information should be obtained from The Registrar (Attention Appointments Officer) University of Cape Town, Rondebosch, 7700 South Africa to whom applications (Quoting reference No AC/11) must be submitted as soon as possible.

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information ont he implementation of this policy is obtainable from the Registrar. (W518) A

#### THE HANNAH RESEARCH INSTITUTE

(for studies relating to the production and utilization of milk) CHEMIST

Applications are invited for a vacant post in the Chemistry Department to undertake studies on the physical properties of milk proteins absorbed onto fat surfaces and the properties of homogenized protein/fat systems. Applicants should possess a first or upper second class honours degree in Chemistry, Biophysics of a related subject and should have at least two

years post-qualifying experience. Appointment would be to the Higher Scientific Officer grade salary scale £8,589. A non-contributory superannuation scheme is

operating.

Further particulars may be obtained from: The Secretary, The Hannah Research Institute, AYR KA6 5HL. to whom applications, including curriculum vitae and the names and addresses of two referees, should be forwarded by 4th January, 1982 quoting reference HRI No. 49.

(015)A

M.R.C. CLINICAL RESEARCH CENTRE (NORTHWICK PARK HOSPITAL) WATFORD ROAD, HARROW, MIDDLESEX HA13UJ

# Electron Microscopist — Cytochemist

We have a vacancy for a non-clinical scientific research worker to work jointly between the division of clinical cell biology and the histopathology section. The work involves developing and applying enzymic methods at an ultrastructural level and the use of techniques in the study of human pathology. The successful candidate would be expected to develop new em cytochemical techniques applying biochemical assays for the localisation of specific tissue phosphatase to both subcellular fractions and whole tissues.

The appointment is for a maximum of 3 years subject to confirmation after the first year and is intended for candidates of immediately post-doctoral or equivalent status, or more senior individuals with less than 3 years post-doctoral experience. Salary within the range £8,296  $-\,$  £13,827 per annum (inclusive of London Weighting) depending on age and experience.

For further information contact Dr T. Peters on 01-864 5311 ext 2139. Apply in writing to Miss B. Shaw for application forms quoting ref 104/1/3963. Closing date for applications 31st December 1981.

# STATENS SERUMINSTITUT (Copenhagen)

# HEAD OF DEPARTMENT

position is available for a professional and administrative head of the Vaccine Department from 1st February 1982 or as agreed upon. Responsibilities will include routine functions and basic and applied research.

The Department produces bacterial vaccines, purifies immunoglobulins, completes other products and purchases vaccines and immunoglobulins from abroad.

The Department, which is implicated in an advisory capacity in questions relating to vaccines and vaccination and in postgraduate education, is a WHO Collaborating Centre for Research and Reference Services for Immunological Biological Products and WHO Laboratory for Biological Standards. In the future the Department will be responsible, in collaboration with the other production departments, for the entire production and control of vaccines and will probably be incorporated with one or several departments in a production section, at a later date.

Candidates should be conversant with production and control of biological products. Experience in microbiological, biochemical and/or immunological methods would be an advantage.

The ideal candidate is a person of proven research ability with a flair for leadership.

The position is permanent, salary 291.700 Danish kroner. The work will be carried out at Statens Seruminstitut, but the appointment is under the Ministry of the Interior.

Applications should be addressed to Her Majesty the Queen and five copies should be sent to the Directors, Statens Seruminstitut, Amager Boulevard 80, DK-2300 Copenhagen S, by 4pm 8th January 198

PLANT Molecular Biology. The Department of Botany, University of Illinois at Urbana-Champaign, invites applications for a tenure-track position at the assistant professor level for appointment in August 1982, subject to budgetary approval. Applicants must have a PhD in plant biology/biochemistry and research interest in genetic engineering as it relates to the basic biology of gene expression in plants and/or the modification of plant genomes. The appointee will be expected to do research in the above area and to contribute to the graduate and undergraduate teaching programs. Salary is open, depending on the applicant's qualifications. Applicants should send at least three references to: Dr Zane B Equal Employment Opportunity Employer. (NW121)A

# SEMINARS and SYMPOSIA

SEMINARS and SYMPOSIA

35th Annual Symposium on Fundamental Cancer Research

"Perspectives on Genes and the Molecular Biology of Cancer"

March 2-5, 1982

This symnposium, sponsored by The University of Texas M D Anderson Hospital and Tumor Institute, will focus on the molecular biology of cancer and explore in depth the metabolism involved in cellular cancer growth. Over 30 lectures and several poster sessions will cover the following topics:

• Gene organization and evolution
• Regulation of gene expression
• Gene transfer
• Novel applications of recombinant DNA technology to human cancer

Speakers will include:
R. Axel, D. Baltimore, J. Baxter, P. Berg, M. Birnstiel, D. Botstein, D. Brown, P. Chambon, D. Clayton, R. Davis, B. DeCrombrugghe, W. Gilbert, W. Hazeltine, L. Hood, R. Kamen, P. Leder, T. Maniatis, B. Mintz, B. O'Malley, D. Robberson, F. Ruddle, G. Saunders, R. Scimke, C. Schmid, P. Sharp, H. Temin, S. Tonegawa, G. Vande Woude, H. Varmus, R. Weinberg, C. Weissman, and R. White.

For scientists interested in presenting poster papers, please send abstracts by Dec. 31, 1981 to

Dr Grady F. Saunders or Dr Donald L. Robberson M.D. Anderson Hospital and Tumor Institute 6723 Bertner Ave.
Houston, Tex. 77030

Registration information may be obtained from Frances Goff, Room 115, at the same address.

tenable for three years at SRC equivalent grant levels. The Research Project will involve free radical chemistry and photochemistry using the fast reaction techniques of laser flash photolysis and pulse radiolysis. Applicants should have a good honours degree (or equivalent) in Chemistry and Biochemistry.

Further details and application form available from the Institute Registrar, Kelsterton College, Connah's Quay, Clwyd. Tel: Deeside 817531 ext 271.

Closing date for receipt of applications within 14 days of the appearance of this advertisement.

## **COLOUR VISION**

A NATO meeting concentrating on the psychophysics and electro-physics and electrophysiology of human and primate colour vision will be held at Cambridge University, August 23-27, 1982, For details please write to Dr. J. D. Mollon, Department of Experimental Psychology, Downing Street, Cambridge CB2 3EB, United Kingdom. (9972)C

# UNIVERSITY **OF NOTTINGHAM** MSc COURSE IN MEAT SCIENCE

Applications are invited from Graduates in appropriate subjects (normally in Agricultural, Bio-logical, Chemical or Veterinary Sciences) for admission to an advanced course of study leading to the degree of MSc (by examination) in Meat Science. The course, which is of one year's duration, includes Production of Meat Animals, Physiology of Meat Animals, Animal Health & Meat Inspection, Commodity Science of Meat and the Economics and Marketing of Meat. A short dissertation based on research of a topic selected from one of these 5 subjects constitutes part of the overall assessment for the degree.

The course is designed to provide those having appropriate scientific training with specialist knowledge of meat whereby they would be suitably qualified to accept responsibility for the scientific control of meat as a commodity in relation to developments within EEC and in world trade generally.

For suitable UK applicants, scholarships may be available.

Those seeking admission for the 1982-83 session should write before February 1st 1982 requesting an application form, from the following:

The Secretary (Ref PG P), School of Agriculture, University of Nottingham, Sutton Bonington, Loughborough, Leics LE12 5RD (9992)C

# **STUDENTSHIP**

**QUEEN ELIZABETH** COLLEGE (University of London) **DEPARTMENT OF PHYSIOLOGY** 

# MICROELECTRONICS EDUCATION PROGRAMME RESEARCH STUDENTSHIP

Applications are invited from graduates with at least second class honours who can combine a biological science training with knowledge of strong interests in the use of microcomputers for a two year studentship investigating the use of microcomputers in physiological and other biological science for classroom experiments. The successful candidate will be required to register for a research degree of University of London.

Curriculum vitae should be sent as soon as possible to Dr I C H Smith at the Department of Physiology, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 (9980)F

# **FELLOWSHIPS**

# 1982 BEIT MEMORIAL **FELLOWSHIPS FOR** MEDICAL RESEARCH

Notice is hereby given that an election of Junior Beit Fellows to begin work on 1 October 1982 will take place in May 1982. Junior Fellowships carry an initial value of £6,880 - £8,515 plus £967 London Allowance, plus yearly increments for three years. There will be the usual university superannuation contributions and benefits. Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Teritories, India, Pakistan, the Republic of Ireland and the United Kingdom, or a medical diploma registrable in the UK. Elections to Junior Fellowships are rarely made above the age of 35 years.

Applications from candidates must be received not later than 19 March 1982. Candidates must submit evidence where they propose to work, which must be in Great Britain or

Forms of applications and all information may be obtained from Professor W G Spector (Secretary), Pathology Department, St Bartholomew's Hospital, London EC1A 7BE. For overseas candidates forms of application may be obtained from, The Secretary, South African Medical Council, PO Box 205, Pretoria, South Africa; The Ministry of Health, The Government of India, New Delhi, India; The Secretary, Department of Education and Science, PO Box 826, Canberra, City, ACT 2601, Australia; The Department of Health, Wellington, New Zealand; and, The Canadian Medical Association, 1867, Alta Vista Drive, Ottawa 8, Ontario, Canada.

# IMPERIAL CANCER **RESEARCH FUND** RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment to work with Dr Ian Kerr on the biochemistry of interferon action, the regulation of the interferon response and the role of the 2-5A system in relation to its wider possible significance in the control of cell growth and development. Experience with proteins and nucleic acids or genetic engineering techniques or membrane biochemistry and some familiarity with handling cells in tissue culture are desirable.

The position is available immediately and candidates should be free to take up the appointment by September 1982 at the latest. Salary range £8,787 to £10,837 (inclusive of London Allowance), with entry according to qualifications and experience.

For further information contact Dr Ian Kerr (tel. 01-242 0200 ext 337). Applications with full CV and the names and addresses of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 1st Junuary 1982 quoting ref. 8/82. (9931)F

# **EMBO**

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

# SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of the application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatiantic travel are awarded only in extremely exceptional circumstances

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.

# Vincent C. Kelley and Leon T. Silver **GRADUATE FELLOWSHIPS** DEPARTMENT OF GEOLOGY THE UNIVERSITY OF NEW MEXICO

The Department of Geology of the University of New Mexico invites applications for the Vincent C. Kelley and Leon T. Silver Graduate Fellowships. The fellowships will be awarded on the basis of the scholastic record and academic promise of graduate applicants. Each fellowship will provide for a generous living stipend of \$1,000/ month for 9 to 12 months, and up to \$2,000/year for travel and research expenses. The Caswell Silver Foundation will pay all tuition and university fees. The awards are made on an annual basis, but may be renewed for up to three years as long as the student maintains excellent academic standing and shows evidence of significant progress in research. Preference will be given to, but is not restricted to, applicants for the PhD program An application for admission to the UNM Graduate Program, tran-Graduate Record Exam scripts, results (verbal, math & geology), three letters of reference and a brief statement of research goals are required for consideration for the fellowships. Application materials may be obtained from: Rodney C. Ewing

Chairman Department of Geology University of New Mexico

Albuquerque New Mexico 87131

The deadline for applications is March 1, 1982 for the Fall semester (NW131)E of 1982.

when replying to these advertisements

# IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment to clone mammalian DNA sequences specifying control regions, structural genes and transforming genes, and to test the expression and biological activity of the cloned sequences by the use of DNA transfection techniques and eukaryotic vector systems.

Salary range £8,787 to £10,837 (inclusive of London Allowance) with entry according to qualifications and experience.

For further information contact Dr M Fried (Tel. 01-242 0200 ext 297). Applications with curriculum vitae and the names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 England quoting reference no. 9/82. (9932)E.

# **POSTDOCTORAL FELLOWSHIPS IN IMMUNOLOGY**

Position available postdoctoral training in basic immunology (idiotypic regulatory mechanisms) and applied problems (tumor immunology and leukemia virislymphocyte interactions). Other related activities in the department include research on biology of interleukins, interferons, and cellular immunity (cytotoxic and NK cells).

Send complete CV and references to: Jan Cerny, MD, PhD, Department of Microbiology University of Texas Medical Branch, Galveston, Texas, 77550.

An Equal Opportunity/Affirmative Action Employer.

(NW137)F

# FIRST ANNOUNCEMENT EIGHTH EMBO ANNUAL SYMPOSIUM 1982 GENETIC FLUX

# 3-7 October 1982 EMBL Heidelberg (F.R.G.)

The seven plenary sessions will cover: Transposition in prokaryotes and eukaryotes; the integration of viruses and DNA; switching gene functions; gene families; repeated sequences; the structure of organelle genomes; and the evolutionary implications of genetic flux.

In addition to members of the Organizing Committee the speakers will include: D. Baltimore (Cambridge-USA); C. Blake (Oxford-UK); B. Burr (Upton-USA); J. Carbon (Santa Barbara-USA); I. Dawid (Bethesda-USA); G. Felsenfeld (Bethesda-USA); G. R. Fink (Ithaca-USA); M. Fried (London-UK); W. J. Gehring (Basel-Switzerland); W. Gilbert (Cambridge-USA); R. Jaenisch (Hamburg-FRG); A. Jeffreys (Leicester-UK); R. Kahmann (Martinsried-FRG); J. Maynard Smith (Brighton-UK); H. A. Nash (Bethesda-USA); K. A. Nasmyth (Cold Spring Harbor-USA); P. Philippsen (Basel-Switzerland); K. Rajewsky (Köln-FRG); H. Saedler (Köln-FRG); J. Schell (Köln-FRG); M. Singer (Bethesda-USA); F. Stahl (Eugene-USA); G. Stark (Stanford-USA); R. E. Streek (München-FRG); S. Tonegawa (Cambridge-USA); A. Toussaint (Brussels-Belgium); R. A. Weinberg (Cambridge-USA); K. Willecke (Essen-FRG).

The Symposium will be held at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 3 October 1982. Plenary sessions will be held in the mornings and late afternoons of 4-6 October and the morning of 7 October. There will be three poster sessions in the afternoons of 4-6 October inclusive. Participants will be accommodated in hotels in Heidelberg, and a small number of inexpensive rooms will be available in the EMBL guesthouse. The registration fee (see below) does NOT cover the cost of accommodation.

Applications for participation, including a curriculum vitae and a brief description of current research interests should be sent to: Dr. J. Tooze, Executive Secretary, EMBO, Postfach 1022.40, 69 Heidelberg, F.R.G. The registration fee is DM 180, for graduate students DM 90, and for participants from industry DM 360. Applications should reach Heidelberg by 15 June 1982. Since the number of participants is limited to 220, the Organizing Committee will notify those who have been accepted in August.

Organizing Committee: W. Arber (Basel-Switzerland), G. Bernardi (Paris-France), W. Bodmer (London-UK), P. Borst (Amsterdam-Netherlands), P. Starlinger (Köln-FRG), and J. Tooze (Heidelberg-FRG). (W513)E

# **EMBO**

**European Molecular Biology Organisation** 

# LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1982 AWARDS

Next deadline: February 19, 1982

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but subject to review of progress they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The followship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 19, 1982. Successful candidates will be notified of the their awards immediately after the meeting of the selection committee which is on April 30, 1982.

Application forms and further details may be obtained from Dr J Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1,F.R. Germany.

(W510)E

# TRINITY COLLEGE

Oxford

# JUNIOR RESEARCH FELLOWSHIP

The College invites applications for a Junior Research Fellowship in the Biological Sciences tenable for three years (not renewable) from October 1982. The Fellowship is intended for those who have completed, or are near to completing, a postgraduate thesis, and there are no teaching duties attached to the post, though such work (up to a maximum of 6 hours a week) may be undertaken with the consent of the College. No age limit is prescribed, but preference will be given to candidates under 30 years of age. The Fellowship is open to both men and women and may be held in conjunction with other appointments.

Applications should reach the College Secretary (from whom further details may be obtained) between 1st and 31st January, and should include a curriculum vitae with a bibliography and the typescript of any unpublished work, an explanation of the nature of the proposed research, and the names of two referees. Candidates will be expected to make themselves available for interview in the last week of February. The College will bear the cost of travel within the British Isles. (9971)E

## UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSICS

POSTDOCTORAL FELLOWSHIP

in Charged Particle Reactions relating to Fusion and Medical Physics

Applications invited for this post tenable for 3 years, to investigate new techniques for making measurements of neutron induced charged particle reactions.

Techniques developed will be applied to measurements related to fusion reactor design and to medical physics. Programme in collaboration with AERE, Harwell, and parts of programme conducted on Harwell Electron Linac.

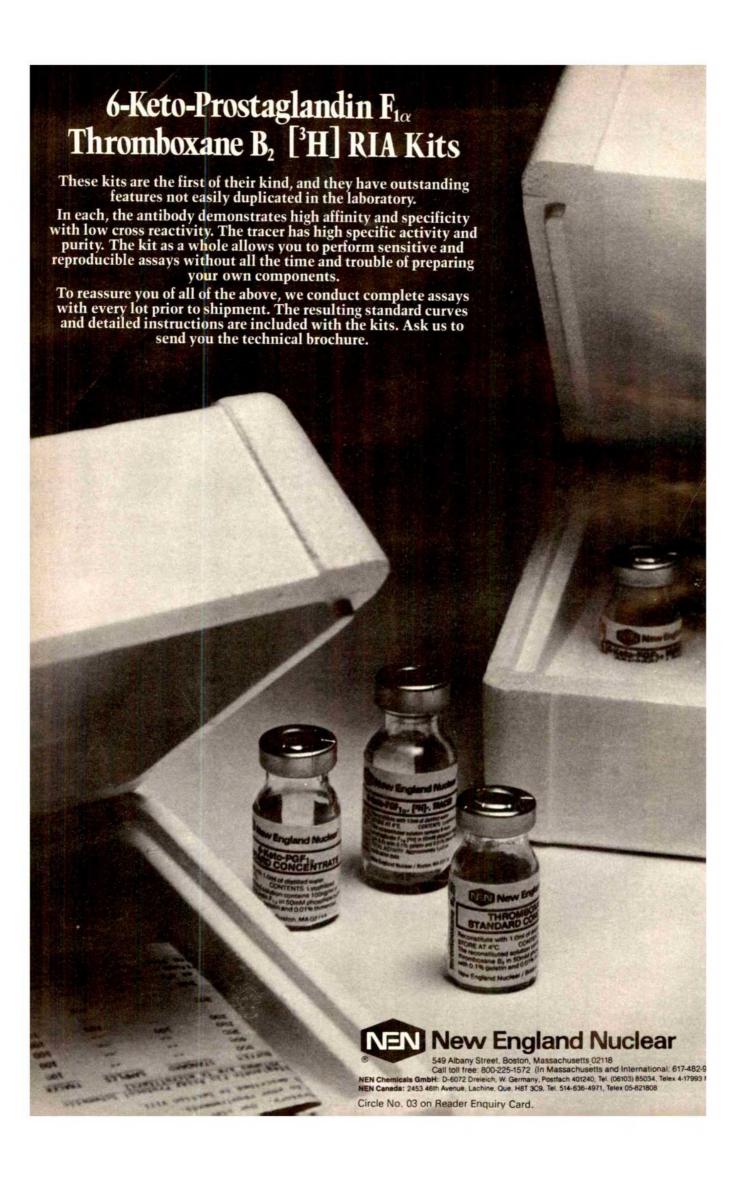

Candidates need not have worked in this field, but should have extensive experience in nuclear or reactor physics experimental techniques, as well as a sound general physics background.

Salary on the Research Fellow 1A scale £6,070 to £10,575 plus superannuation. Maximum starting salary £7,700.

Further particulars from Assistant Registrar, (Sci & Eng), PO Box 363 Birmingham B15 2TT to whom applications (3 copies) including curriculum vitae and naming three referees should be sent by *Thursday*, 31 December, 1981.

SFA AT VILW THE GLOBE

# IJTROPHOR

Put wavy bands where they belong. Among yesterday's problems.

Banish wavy bands with Ultrophor, a unique new instrument designed exclusively for professional electrofocusers by LKB, electrofocusing pioneers since 1960.

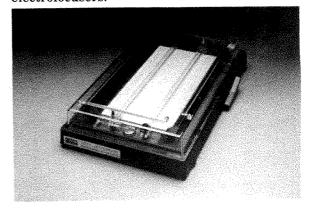

The ultracompact Ultrophor will cope with any analytical or preparative electrofocusing situation thanks to its radically new approach to electrode design, the construction of the highly efficient glass/aluminum cooling plate and the opportunity for atmospheric control.

The impressive list of bonuses include the flexibility of being able to run gels of any length up to 26 cm long or gels of any thickness, especially capillary-cast ultrathin gels, with less chance of wavy or skewed bands. The Ultrophor also has an unmatched capability to run high pH gels for sharp separations of alkaline samples as well as handle oxygensensitive or other labile samples.

Not only do you save valuable lab space with the compact Ultrophor but you save on time too because it's so fast and convenient to use and super-easy to clean. Like all LKB units, the new Ultrophor boasts a complete backup system and comprehensive technical support.

Contact your nearest LKB representative today for full information.

Ultrophor - the straight choice for professional electrofocusers.

# Monoclonal Antibody SCREENING SYSTEMS

for murine immunoglobulins

They save time –

The ELISA method employed yields a rapid and dramatic color development in the presence of positive clones. It's faster than conventional RIA and can be used with visual, manual spectrophotometric, or fully automated processing.

They avoid trouble –

Our reagents are pretested and optimized in each screening system to prevent unwanted variables from spoiling your results.

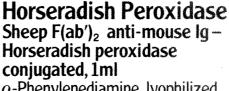

They're complete and ready to use –

Detailed protocol and specific titer information are provided with the pretested components:
Enzyme-conjugated second antibody Color development agent
Dilution buffer

Washing buffer Substrate buffer

Our technical bulletin illustrates how easy it is to use the ELISA method. Send for it.

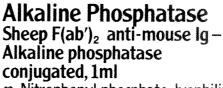

o-Phenylenediamine, lyophilized Dilution, washing and substrate buffers NEI-601 ( $\sim$  10,000 assays)

Goat anti-mouse Ig – Horseradish peroxidase conjugated, 1ml

o-Phenylenediamine, lyophilized Dilution, washing and substrate buffers NEI-602 (~ 20,000 assays)

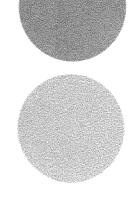

p-Nitrophenyl phosphate, lyophilized Dilution, washing and substrate buffers NEI-603 ( $\sim$  10,000 assays)

Sheep anti-mouse Ig – Alkaline phosphatase conjugated, 1ml

p-Nitrophenyl phosphate, lyophilized Dilution, washing and substrate buffers NEI-604 ( $\sim$  20,000 assays)

Not for use in humans or clinical diagnosis.

# Constant power. Faster electrophoresis.

ISCO's constant power can provide you with faster separations and sharper zones, especially for isoelectric focusing and high performance discontinuous buffer techniques. The Model 494 has an automatic crossover circuit that switches control to a different mode whenever a preset power, voltage, or current limit is reached. It also has a unique ground fault detector which often indicates faults before you turn the power up, because it monitors ground capacitance and resistance instead of leakage. A wattmeter continuously tells you the power output—there's no need to multiply current and voltage readings. And finally, you get 2000V but pay only \$1495.

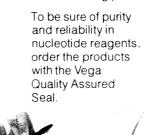

Find out how you can buy an ISCO third generation constant wattage power supply for less than someone else's first try, and get substantially better specifications too. Send for your ISCO catalog today, or phone toll free [800] 228-4250 (continental USA except NE). ISCO, box 5347, Lincoln, Nebraska 68505.

Instruments with a difference

# Our nucleotide reagents pass the toughest test of all.

Before a Vega product is shipped to you, it has to meet the rigid quality standards of Dr. Erwin Peters, Manager of Quality Assurance. Using the latest analytical equipment, trained technicians quantifatively and qualitatively test every Vega product. From raw materials to finished products, quality assurance procedures are required in every step of the manufacturing process.

# Protected Mononucleotide Phosphotriesters

# Immunoelectrophoresis A new Pharmacia system for all occasions

# **Flexible**

Immunoelectrophoresis and agarose zone electrophoresis in any size gel up to 114×225 mm.

# Fast ·

High efficiency cooling plate permits high voltage runs powered by a 500 V/400 mA power supply.

# Convenient

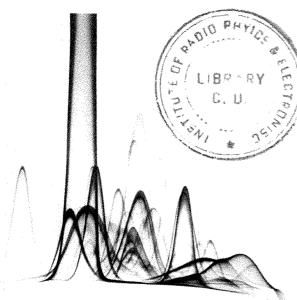

Removable buffer vessels allow easy remixing.

# Complete

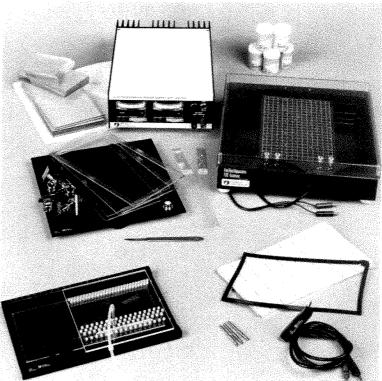

A full range of accessories for casting and punching gels.

# Easy

A complete instructions/methodologies manual included to make any technique a simple task.

Pharmacia Fine Chemicals AB Box 175 S-751 04 Uppsala 1 Sweden

# Agaroses for all occasions

Order

Type A Medium electroendosmosis for electrophoresis and most immunological techniques.

Type B High electroendosmosis for counter immunoelectrophoresis and diffusion techniques.

Type C Low electroendosmosis for crossed immunoelectrophoresis.

Agarose IEF A special grade for isoelectric focusing.

Send for complete information on the immunoelectrophoresis system for all occasions.

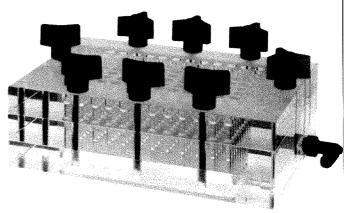

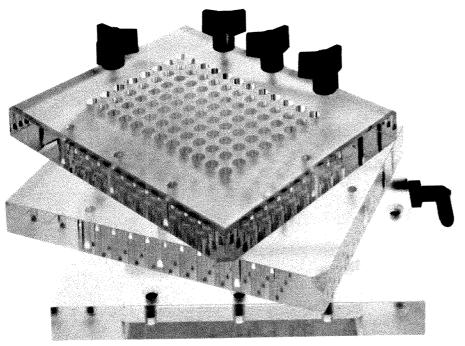

# Hybri-Dot

# For low cost, time-saving hybridization to "dots" of target DNA and RNA

BRL has designed a 96 well manifold that simplifies scale-up of the sensitive "dot hybridization" procedure for detection of specific DNA and RNA sequences. In this procedure, as little as one picogram of a specific nucleic acid sequence, bound to nitrocellulose as a small spot, can be detected using  $^{32}$ P-labeled probe ( $\sim 10^8$ dpm/ $\mu$ g). Dot hybridization has been used to detect viral DNA in lymphocytes and in serum.

The 3 mm diameter sample wells of the BRL® Hybri●Dot™ System are arranged to precisely match the array of a standard 96-well microtitration plate. This simplifies and accelerates procedures such as the large-scale screening of bacterial colonies for recombinant plasmids.

**BRL No. 1050MM** 

# **Features**

# 96-Well Design Compatible with "Microtitration" Plates

Conveniently adapts to protocols using 96-well plates. Avoids time consuming tube handling and labeling.

# 3 mm Diameter "Spot"

Readily detects picogram quantities of nucleic acids hybridized to low levels of radioactive probe for conservation of valuable reagents.

# Pre-cut, Indexed Nitrocellulose Sheets

Each Hybri®Dot™ System includes ten sheets of pre-cut nitrocellulose. Notched corners assure accurate reference afterremoval from the system.

# Easy-to-Assemble, Precision Design

Unique, precision milled surfaces assure a secure, fluid-tight seal without gaskets, Orings or special tools.

BRL welcomes all questions concerning the performance of the Hybri•Dot™ System. Ask for a BRL Technical Services Representative at (800) 638-4045. To place an order, contact Customer Services Department at (800) 638-8992.

# Amersham offers 3'-end labelling kits which give you:

# Convenience

All the reagents needed to label DNA in one kit.

# **Flexibility**

Amersham's kits are available with or without cordycepin 5'- $[\alpha^{-32}P]$ triphosphate for maximum economy of label.

# **Efficiency**

Labels all 3 types of 3'-end – protruding, blunt and recessed.

# Simplicity

Few pipetting steps. Easy to handle volumes.

# Quality

All batches of our kit are subject to rigorous quality control. A copy of the autoradiograph, obtained after labelling the standard DNA provided in a standard reaction, is supplied with each kit.

**PB.4025** Non-radioactive reagents  $+250\mu\text{Ci}$  cordycepin 5'- $\{\alpha^{-32}\text{P}\}$ triphosphate, sufficient for 5 standard 3'-end labelling reactions.

**PB.4100** Non-radioactive reagents + 1mCi cordycepin 5'- $\{\alpha^{-32P}\}$  triphosphate, sufficient for 20 standard 3'-end labelling reactions.

**N.4005** Non-radioactive reagents only – sufficient for 5 standard 3′-end labelling reactions.

**N.4020** Non-radioactive reagents only – sufficient for 20 standard 3'-end labelling reactions.

Please call Amersham or your local representative for further details of our kits.

# MISCELLA

100 years ago **Books** received Announcements Classified advertising 518

XVİ xvii

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

# JANSSEN PHARMACEUTICA LIFE SCIENCES PRODUCTS

# introducing Colloidal Gold Coated Immunoglobulins for use in the new IGS\*-method

\*Immuno Gold Staining

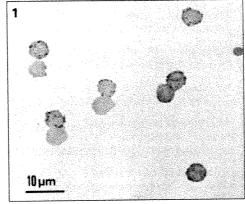

# The new IGS-method

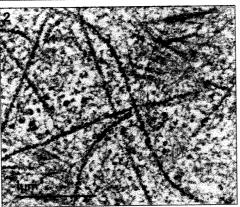

Colloidal gold, is an excellent marker for immunoelectron microscopy (reviewed in Ref. 1). Recently, it has been found that it can also be used at the light microscopic level (2) as a red stain, in the new IGS (immuno gold staining)-method (3).

A two-step and a bridge IGS-method have been worked out. For the two-step IGSmethod, the colloidal gold reagents contain anti-antibodies. For the bridge IGS-method, they contain immunoglobulins isolated from pre-immune serum from the same animal species as the primary antibody. The colloidal gold reagents serve as antigens and are linked to the primary antibodies by a bridge anti-antibody. For example, for monoclonal mouse antibodies, goat antimouse/lgG and colloidal gold/mouse immunoglobulin are used. The typical red colour produced by the IGS-method comes from large numbers of gold granules accumulating over antigencontaining structures. The IGS-method can of course also be used for immunoelectron microscopy.

We provide gold granules of different mean diameter (5, 20, 40 nm) coated with immunoglobulins for both the two-step and bridge IGS-methods, and for both light and electron microscopy.

Circle No. 17 on Reader Enquiry Card.

1 Indirect IGS-labelling of human T-lymphocytes, using monoclonal antibodies (6). Positive cells show patches of IGS-reagent (GAMG40).

2 Thin section of a PtK₂-cell stained in toto with anti-tubulin and GARG5 (3). Microtubules are covered with gold particles. Glutaraldehyde fixation and Triton X-100 permeabilization.

# The Immune System

The 125 articles assembled in these two volumes are striking evidence of the advances in basic immunology made possible through the theoretical and experimental foundations laid by Niels Kaj Jerne. Articles, contributed by Jerne's colleagues and associates, cover all areas of basic immunology in a combination of review articles, essays, and original research reports. Collectively, the authors represent a significant fraction of the world's scientists now conducting important work in basic immunology. The high quality of contributions and the broad range of their coverage make this Festschrift an appropriate tribute to both the stimulating force of Jerne's work and the extent of its influence on contemporary immunology.

Topics covered in 'The Immune System' Networks and Complex Systems – Evolution and Ontogeny – Antibodies and B Cell Function – Antibody Specificity and Diversity – T Cell Function – Major Histocompatibility Complex – Cell Membrane – Tolerance and Suppression – Allotypes and Idiotypes - Factors, Hormones, Interferon - Lymphoid Tissues - Growth of Cells in Culture - Cancer -Parasitology and Infectious Disease

# The fraction collector that turns science fiction into science

Just a few years ago no one would have believed that a fraction collector like SuperRac could exist. Most researchers were used to their constant-volume and constant-time collectors – with level-sensors at best.

Many were resigned to a compromise between resolution and the efficient use of collection vessels.

SuperRac will change all that.

To begin with, SuperRac has built-in slope detection. Unlike a simple level sensor, it cuts peaks at their true beginnings and ends. You can even collect unresolved peaks in well-resolved fractions . . . and you never need to worry about baseline drift.

SuperRac also diverts uninteresting eluate to a waste trough – via a valve –

so you use fewer test tubes.

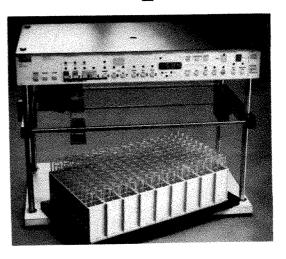

SuperRac's memory stores five different collection procedures that you can recall at the touch of a button. It has nine time windows allowing you to limit collection to interesting parts of your chromatogram.

SuperRac automatically compensates for asymmetric peaks and peak-width broadening during an isocratic elution. And it continues to run the pump for a specified time after a collection to clean and equilibrate the system.

Ask your local LKB distributor for more information on the new SuperRac. He'll give you several more reasons why we named it Super.

A safe place for your cell cultures.

In the Heraeus Incubators for Cell Cultures, all environmental parameters are ideally matched to the natural environmental conditions of the cells:

- Electronic temperature control
- Electronic CO2 and O2 control
- Electronic humidity control
- Pyrolytic germ barrier for protection against contamination
- Hot air sterilization at 180°C
- Temperature range: 3 to 50°C

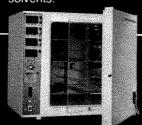

Petriperm®

A novel culture dish with gaspermeable base with hydrophilic or hydrophobic surface

- UV permeable 200 nm
- No inherent fluorescence
- Suitable for high-power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation.
- Chemically resistant to acids, bases and organic solvents.

# SPECIAL OFFER

TO ALL READERS OF NATURE

OLYMPUS started the true pocket recorder revolution when they developed this light weight, high precision and exciting new MICROCASSETTE PEARLCORDER system for business and pleasure.

We offer readers part of this revolution with the latest and advanced 2 speed OLYMPUS PEARLCORDER \$802. The capstan drive 8 oz MICROCASSETTE will give you up to two hours recording and play-back. (Unlike Mini-recording machines). The S802 is a light weight complete miniature recording system, capable of accepting verbal notes, record business meetings, computer programmes and even your favourite music. The S802 has a comprehensive range of attachments, including sub-miniature microphones, remote control, conference room amplifier, telephone pick-up, TRANSCRIBER for your secretary etc.; all this together with a 1 year guarantee from OLYMPUS, makes the S802 an absolute must for all busy Businessmen and Women both at home and at work. In addition we offer a 14 day complete money-back guarantee, at a price which we believe like the S802 is unbeatable. Batteries not included.

- Record Button
- Volume Knob External Microphone Jack
- Earphone Jack
- **Built-in Microphone**
- Shift Knob
- 8. Tape Counter
- Eject Button
- 10. Reset Rutton REW-STOP-PLAY
- 12. 13. Tape Speed Selector Remote Control Jack
- Record/Battery Check Lamp 14. DC Power Source Jack

TO ORDER Simply complete the order form below and sent it together with your payment to Tenbart Business Systems, Tenbart Limited, FREEPOST, London, EC4B 4TL. TO ORDER BY PHONE Telephone 01-583 1626 and quote your credit card Circle No.14 on Reader Enquiry Card.

To: NATURE 802 OFFER

TENBART LTD, FREEPOST, LONDON EC4B 4TL (NO STAMP REQUIRED)

Please send me \_Pearlcorder 802/S at the special price of £59.95 each inc of p. and p.

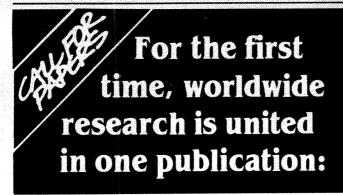

I enclose my cheque for £ made payable to "Tenbart Ltd 802 Special Offer" or debit my Access/Barclaycard No. \_

# INTERNATIONAL JOURNAL OF LASER CHEMISTRY

Managing Editor: R. J. Vetter Maître de Recherches, CNRS, France

Now chemists and physicists working in the rapidly developing field of laser chemistry can share their research in the pages of a single publication designed for a worldwide readership. The international character of this new publication is ensured by the Editorial Advisory Board (opposite). Letters, articles, and reviews prepared for rapid publication will be welcome.

The INTERNATIONAL JOURNAL OF LASER CHEMISTRY intends to publish the results of theoretical and experimental investigations and developments in laser light applications in different fields of chemistry: chemical physics, physical chemistry. inorganic and organic chemistry, chemical technology, analytical chemistry, biochemistry and other areas.

The journal will publish review papers covering the following actively developing trends which presently are scattered in many other journals:

Laser study of elementary chemical reactions. including state-to-state chemical reactions Laser-induced chemical reactions Multiple photon IR laser photophysics and photochemistry

Laser photoseparation processes, including laser isotope separation, laser purification of materials, etc. Laser-induced processes at surface Laser analytical chemistry

Laser experimental techniques including tuneable lasers for chemical applications etc.

We invite you to submit reports of original work on these and other aspects of laser chemistry for this forthcoming journal from Harwood Academic Publishers. Papers should be sent directly to each regional editor (please consult the Editorial Advisory Board opposite for your area). Rapid communications can be submitted incamera-ready form. Publication of the first issue is scheduled for June 1982, and will be bimonthly.

For helpful NOTES FOR CONTRIBUTORS please write to the publisher at the address below.

INTERNATIONAL JOURNAL OF LASER CHEMISTRY June 1982 six issues per volume \$120 £66 per volume

Price and publication date may be subject to change

# Not a revolution, more a Trojan horse

The House of Lords committee on science and technology has produced a guileful recipe for change. Will the British government listen to what it has to say?

In the nineteenth century, when the British government felt threatened from abroad, the natural response was to build a few more battleships, Now, when most threats are economic rather than strategic, the temptation is to carry through yet another reorganization of the administration of science and technology. Untrue to form, the present British government has been restrained almost to the point of seeming indifferent on the issue, and masterful inaction may indeed be appropriate. For although there is a long-term connection between national prosperity and the efficiency with which research and development is administered, the short-term consequences of tinkering are usually disadvantageous. Yet it is also plain that the machinery of research administration in Britain has for years been out of date. The British government should thus be grateful for the thoroughly sensible report of the House of Lords Committee on Science and Technology, published this Monday. Whether gratitude will flow is naturally quite a different matter. Indeed, from the point of view of a government so embattled on other fronts that it may be forgiven for seeking respite where it can find it, the advice it has received from the House of Lords has the unwelcome attributes of being at once persuasive and practicable.

More clearly than its predecessors, the House of Lords committee has distinguished between the two functions of science (and scientists) in government — the management of research and development and the provision of scientific advice on broader questions of policy. The distinction has been made before, most recently by Dr Martin Holdgate's inquiry into the role of the scientific civil service within the British government, but it has not sunk in. The point is, however, both simple and crucial. Government departments sustain (or should sustain) substantial programmes of research and development and should manage them efficiently. They also need some mechanism for being told from within which policies make scientific sense and which do not. Lorth Rothschild's proposals in 1972 for the reorganization of civil science supposed that if the spending departments of government were provided with chief scientists of sufficient stature, both functions could be carried out by the same people. The experience of the past decade has, however, shown that most chief scientists have been imprisoned by the management of research and development. The House of Lords suggests that this danger could be avoided by appointing two people within each ministry, one to advise on general policy and one to manage the research programme. That is one solution to an immediate problem. A better one would be to ensure that chief scientists should be strengthened, and equipped, to carry out both functions. Either way, something must be done, both departmentally and for central government.

The way in which chief scientists in British government departments have been converted by the pressure of work from putatively subversive agents of change into high-grade clerks is not, however, the only failure of the post-Rothschild era. Even at the outset, it was clear that the Rothschild reorganization entailed the risk of emasculating crucial parts of the previous machinery for providing the government with scientific advice. Thus the old Council for Scientific Policy, which had become fond of writing

(and, to its credit, publishing) reports on matters of general importance, was replaced by the Advisory Board on the Research Councils, a referee to arbitrate between the research councils which appears even to have given up the practice of saying how it purports to do so. The nearest entity within the British government to a central source of advice on science policy is the committee know as the Advisory Council on Applied Research and Development — a busy committee conspicuous chiefly for its lack of power and coherence. The House of Lords committee proposes that this committee should be transformed by some kind of evolutionary process into a Council on Science and Technology, that it should report to some member of the British Cabinet who, while not being a Minister of Science and Technology, would be spokesman in this cause and that the committee should be serviced by the member of the Cabinet Office with responsibilities in this field while its chairman should have access to the nominated minister.

The proposal is sensible. In British terms, it is also devilishly clever. Strengthening a committee is, after all, a good thing to do; setting up a new committee would be unpalatable. Giving an existing minister wider responsibility will seem productive; appointing another would be counted as an encouragement of the growth of bureaucracy. The House of Lords committee has also been politic in the modesty of its requirements of defence research and development. It asks not that there should be a means by which the true ivory tower of British science (defence research) should be coordinated with the rest, but merely that there should be cross-representation on the appropriate committees and that everybody should bend his energies to ensure that what the government spends on defence research should not continue to have no commensurate civil benefit. Cleverly, however, the committee asks that its new council should have some right to ask questions about the interface between defence research and civil industry. It would, of course, have been impolitic to recommend that the committee should have the right to ask what defence research is for

With a little luck — and if the committee's friends do not too eagerly disclose their reasons for believing that it is right — the outcome may be a more intelligent way of running that part of British science and technology supported by the public purse. That is as it should be. Pinstriped gentlemen have for too long been turning up at pointless committee meetings in order to agree that it would be better if there were time to talk about matters of substance, not of procedure or of who gets how much. That the committee's recipe for the administration of civil science is to return to the 1950s, when there was a cabinet minister with parttime responsibility for science and technology and an advisory council whose power derived from its reputation for plain speaking (but not good judgement) is not in itself a reason why the recipe should not be tried. For something, even anything, must be done. It cannot be in the private interests of even British governments that they should feel free to decide, without internal dissent, to rob the academic research base of essential support, discovering only afterwards that they have erred. That, however, is what is now in prospect.

# US dispute on nuclear bomb safeguards

# Agency and Administration at loggerheads

Washington

The State Department and the Nuclear Regulatory Commission (NRC) are drifting towards loggerheads on antiproliferation safeguards. Both parties agree that the safeguards administered by the Vienna-based International Atomic Energy Agency (IAEA) need to be improved. The State Department, reflecting a general drift away from the policies of the Carter Administration, would prefer to use conventional diplomatic channels.

In contrast NRC, which under the Nuclear Non-Proliferation Act signed by President Carter in 1978 is required to assure Congress about the adequacy of IAEA safeguards, is pushing for a more direct approach. Following sharp criticism of IAEA procedures by two former inspectors (Nature 26 November, p.300), the five members of the commission have sent a letter to all members of Congress saying that the current safeguards system "would not detect a diversion in at least some types of facilities".

In the light of this concern and the general shadows that have recently been cast over the adequacy of IAEA safeguards, NRC has decided to carry out a review of its own policies on granting export licences for nuclear materials. The State Department, however, although embarrassed by disclosures about weaknesses in IAEA's safeguards system, does not seem to feel any such drastic action is necessary. Addressing the Senate Foreign Relations Committee last week, Mr Richard T. Kennedy, Under-Secretary of State for Management and a former member of NRC, repeated the Administration's commitment strongly to support the agency.

Introducing the Senate hearings, committee chairman Senator Charles Percy emphasized the central importance of IAEA, and pushed Mr Kennedy hard on whether the Administration was doing everything it could to prevent the spread of nuclear military technology, complaining that the Senate had been provided with insufficient information on procedures agreed with Pakistan and IAEA to prevent the diversion of civilian technology. Senator Percy put the suggestion strongly denied by Mr Kennedy — that the Administration might be going "soft" on non-proliferation to help boost the sagging exports of the domestic nuclear industry.

Democrat Senator John Glenn went

even further, suggesting that the State Department should put pressure on other industrialized countries to provide a significant increase in technical and financial resources for the agency. To support his argument that such increases were badly needed, Mr Glenn produced a report prepared at the Pacific Northwest Laboratory under contract to the Department of Energy throwing doubt on whether IAEA was able to achieve its technical objectives of the surveillance and accounting of nuclear materials.

One issue on which there was little disagreement between Senator Percy and the Administration was over attempts by Third World countries to gain greater influence on the activities of IAEA, both in terms of increasing their membership of the governing council and in appointing more inspectors from the developing nations. On the latter point it was agreed that, although an important objective, it should not be pursued at the price of sacrificing the quality of inspection procedures. On the other hand, Mr Kennedy made it clear that the State Department would resist attempts to "politicize" the agency, in terms of changing the current balance of control.

There is a deeper division over the extent to which a lack of detailed information about the technical data used by IAEA in

# Is creation a science or a religion?

Little Rock

The state of Arkansas was accused on Monday morning of making "an unprecedented attempt to legislate what is science" at the opening of a trial over its efforts to determine how different theories of the origins of man should be taught in its public schools.

The American Civil Liberties Union (ACLU) is challenging as unconstitutional a law, passed by the state legislature earlier this year, which requires that whenever the Darwinian theory of evolution is taught, an equal amount of time should be devoted to presenting evidence in favour of what is described as "creation science".

ACLU contends that the law violates the first amendment to the constitution, which requires a strict separation of church and state. It argues, in the words of Little Rock attorney Robert M. Cearley, that "creation science is not science but religious apologetics, an attempt to prove or justify sectarian religious beliefs". The state argues that there is nothing inherently religious in teaching that the world came into being as the result of a positive act of creation, and that the evidence used to support this hypothesis is "at least as scientific" as the evidence for the "evolution science".

Setting the agenda for a debate that is likely to dominate the trial, state attorneygeneral Stephen Clark responded in his opening statement that "this is not a trial about religion but a trial about science".

In 1968, the United States Supreme Court struck down as unconstitutional a state law forbidding the teaching of evolution on the grounds that it contradicted a literal interpretation of the Bible. This time the issue has been reversed. ACLU has brought the case on behalf of 23 local religious leaders, biology teachers and schoolchildren, claiming that the new law infringes their rights to freedom of religion.

"For practical purposes it is a tremendously important case for us because it is the first of its kind, and the decision of the court will get a lot of attention", said ACLU staff attorney Jack Novick before the case started. He pointed out that a similar bill has recently been passed in Louisiana, and that others are pending in up to twenty more states.

Three complaints are being made by ACLU. The principal charge is that the law violates the first amendment to the constitution. It is also being charged that the law infringes the academic freedom of teachers and schoolchildren, since it imposes conditions under which evolution can be taught; and that the language in the bill is unconstitutionally vague.

The state attorney-general in disputing each of these charges claims that, since there is nothing necessarily religious in the idea that the world came into being at the hands of some undefined form of creator, there is no problem with the constitution.

Each side will introduce a string of scientific witnesses to support its case. For ACLU, these include prominent academics in fields such as biology, geology and palaeontology; the state plans to introduces qualified scientists who claim their results substantiate the creationist theory of origins. Furthermore, unlike previous cases in which the relative merits of the two explanations were directly compared, this time the focus will be as much on the philosophy of science, with Judge William Overton deciding what types of ideas and reasoning can be described as "scientific" and "religious".

The case is expected to last for two weeks. If ACLU loses, it is already promising that it considers the case so important that it will take it as far as the Supreme Court, which has ultimate say on constitutional issues.

If the civil liberties group wins, then Mr Novik says it will press for full payment of its legal costs — calculated to be several hundred thousand dollars — against the state of Arkansas. But in that case, the state is expected to appeal against the verdict. So either way, the full legal debate is likely to last for a long time. David Dickson

reaching many of its conclusions makes it difficult to check on whether the agency is doing a good job. NRC member Mr Victor Gilinsky expressed concern that protection given in IAEA statutes to industrial, secret or other confidential information has been interpreted in the broadest manner to withhold information about the safeguards system.

Suggesting that undue secrecy made it difficult for NRC to fulfil its responsibilities for checking the adequacy of IAEA safeguards — responsibilities whose legal status still remains ambiguous — Mr Gilinsky said that the commission believed more information should be reported to IAEA's board of governors by its secretariat, and that the United States should try to obtain better information on overall international safeguards effectiveness and on any significant safeguards problems in countries receiving US exports.

Mr Kennedy replied that the general limitations on the agency's role — such as the substantial amount of classified information which it could not release — are "simply facts of international relations... The IAEA safeguards system entails a unique compromise of sovereign rights by many nations, and it is certainly no surprise that this compromise is subject to specific limitations". David Dickson

# Germany's breeder

# Gap unbridged

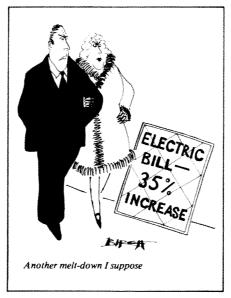

Ulm, West Germany

Rapidly rising costs are threatening the future of West Germany's SNR-300 fast-breeder reactor, with government and public service utility companies still arguing over who should foot the the increased bill if the project is to continue.

The Minister of Research and Technology, Andreas von Bülow, has succeeded in extracting from the utilities an increased financial contribution to the SNR-300 plant at Kalkar. At the end of October he announced that Rheinisch-Westfälisches Elektrizitätswerk (RWE), the leader of the owner/operator utility group, is willing to put up an additional DM 375 million. Two other utilities not so far involved in the project, Preussenelektra and Nordwestdeutsche Kraftwerke (NWK) are prepared to contribute DM 172 million.

Even so these pledges fill only half of a total shortfall of DM 1,100 million created by recent cost overruns. The federal government is unwilling to provide the extra funds from its own budget, and insists that the full amount should be paid by West German industry and in particular by the utilities, each financing a fraction corresponding to its share of electricity generation. "It is perfectly clear," von Bülow recently said, "that without an increase in the participation of the utilities, the future of the fast breeder is in danger and a halt to construction before the end of the year cannot be ruled out".

The weeks ahead will show whether von Bülow's warning is merely a tactical ploy or whether there is a real chance that work on the fast breeder will stop. Although budgetary problems have triggered off this latest confrontation, if the minister regarded the fast breeder as an absolute economic necessity it seems likely that he could accommodate the necessary additional DM 550 million over five years (DM 110 million a year) within this present budget - the ministry has a proposed total budget of DM 6,600 million for 1982 and an energy research budget of DM 2,550 million. "The present situation," he said, "necessitates a reconsideration of the original objectives of government support." At the same time the minister announced that government funds for microelectronics and biotechnology will be increased over the next few years.

Political uncertainty is one of the reasons why the utilities are reluctant to shoulder an increased share of SNR-300 costs. The Bundestag has reserved to itself the decision on whether the SNR-300 should be put into operation when completed. The utilities hesitate to commit themselves as long as this uncertainty persists, and the pledges made so far are contingent, among other conditions, on a positive decision from the Bundestag.

Licensing uncertainties have been another major obstacle – but here at least the greatest difficulties appear to have been overcome with the passing of the fourth part of the licence on 15 October.

Some utility companies originally argued that SNR-300 is a national project that should be financed from taxpayers' money. It remains to be seen whether they will soften their stand in the face of a threat to abandon the project. The West German utility association, VDEW, is now discussing alternative finance strategies including a research and development levy on electricity sales modelled on the present subsidy for West German coal used in the generation of electricity.

Otto Keck

# Israeli education

# More gloom

Tel Aviv

The complaint that cuts in higher education could seriously endanger Israel's scientific potential in the 1990s ran through the symposium organized at the end of November by the Israeli popular science magazine *Mada* to celebrate its twenty-fifth anniversary. Ironically, the symposium coincided with the *Israech* exhibition, a celebration of recent Israeli achievements in applied science.

While Isratech celebrated the success of Israel's funding policy, which for the past decade has emphasized applications, symposium participants maintained that, unless investment in higher education is stepped up, Israel's advantage in many sectors of technology could prove short-lived. The symposium was chaired by the physical chemist Dr Ephraim Katzir, formerly Katchalski, who produced the 1968 report which effectively switched government emphasis from pure to applied research.

Unlike other new states, Israel has a research infrastructure which antedates independence and which is based on institutions such as the Technion, the Weizmann Institute, the Hebrew University and the Volcani Agricultural Institute. Until the late 1960s, Israeli science policy was aimed at more of the same. The Kachalski report redirected government attention to the needs of industry. Only some of Katchalski's recommendations were implemented. Chief scientists were established in ministries involved in research and development, but the proposed upgrading of the National Council for Research and Development failed to materialize — indeed, in 1977, it was actually downgraded. being transferred from direct responsibility to the Prime Minister's Office to the new Ministry of Energy and Infrastructure. At the same time, all spending on research has been eroded by inflation, now 133 per cent a vear.

Even so, the post-Katchalski era has produced a number of achievements. Industry has done well, and now employs more science graduates. Agriculture has seen a steady stream of advances in crop breeding, soil chemistry, irrigation techniques and such novel methods as the sterilization of soils by solar energy. Both production and productivity have increased.

The symposium was chiefly alarmed by the other side of this coin – the continuing absence of a national science policy and the continuing brain-drain to the United States and Europe. The participants blamed people's willingness to leave on the cutbacks in university finance and the mismatch between what universities teach and what industry (and students) demands.

In the past ten years, there has also been a stagnation of student numbers in the exact sciences while total student numbers have soared. The underlying reason is not clear, although the decline has been greatest in the "traditional" fields such as civil engineering, while the most modern departments such as computer sciences are full to overflowing. This suggests that the universities are failing to adapt to modern trends — an ironic conclusion when they themselves have founded such institutions as the Institute of Forward Planning at Tel Aviv or the Neimann Institute at the Technion to act as potential policy advisers.

Employment problems are exacerbated by the relatively small payrolls of the new science-based industries. Would-be students therefore think twice before investing some five or seven years — delayed by a further three years military service — in an exact science when the job prospects are so uncertain.

The Jerusalem College of Technology, which was specifically founded to train the expert workforce the country needs, may be an exception. It is a relatively small and religious foundation where the all-male students study Judaism in the mornings and technical subjects to first degree level in the afternoons and evenings. The "new pioneering spirit" described by the founder and rector, Professor William Low, has presumably helped to take the edge off job uncertainty.

Perhaps inevitably, the symposium produced a gloomy forecast for the next couple of decades. According to Professor Joshua Yavner of Tel Aviv University, unless the government stops the cuts in higher education, Israel will suffer the loss of its main "natural resource" - educated manpower. Hitherto, the University Grants Committee, which administers the government's block funding of higher education, has tried to restrict the cuts to ancillary and non-academic fields (although library budgets have been considerably curtailed), but a point will soon be reached where no more such economies are possible. Then, inevitably, the output of science graduates and PhDs will begin to decline, and the new science-based industries, founded on the expertise of those who graduated in the 1960s and early 1970s, will fail to achieve their early Vera Rich promise.

# US research patents

# **Conflicts arise**

Washington

United States universities are lobbying hard in defence of their newly-won right to an automatic patent on all inventions arising from federally supported research. They are alarmed that their rights may be circumscribed in what may be the most profitable field — genetic engineering.

Two weeks ago, the House of Representatives Science and Technology Committee approved an amendment to a draft bill on patent rights, already approved by the Senate, to exempt the results of research using recombinant DNA techniques from

the broad provisions of patent legislation passed by Congress last December.

The amendment was offered by Representative Albert Gore of Tennessee, chairman of the committee's investigations and oversight subcommittee, and follows his criticism of an an agreement between Massachusetts General Hospital (MGH) and the German chemical company Hoechst that would, he claims, allow the company to benefit unfairly from research paid for by the US taxpayer (*Nature* 18 June, p.525).

Several Washington-based groups representing research universities have protested, saying that this amendment undermines the whole purpose of the new legislation, which is to speed the transfer of research results to private companies. They point out that three years ago, after consulting universities and industry, Dr Donald Fredrickson, then director of the National Institutes of Health (NIH), concluded that no special arrangements need be made for the application of patent laws to genetic engineering research.

An aide to Mr Gore said last week that the congressman might agree to withdraw the amendment before the draft bill reaches the floor of the House for discussion. The Senate has already passed such a bill which even expands the scope of last year's legislation to include not only universities and small businesses but all companies receiving federal research funds, and Senate aides said last week that they were totally opposed to the House committee's amendments.

However, Mr Gore still seems keen that the bill should make a sharp distinction between the control of research results funded from public and private funds. This could complicate efforts by NIH to interpret the new law's provisions on jointly funded projects.

Under the terms of the MGH/Hoechst agreement, the company will provide the hospital with up to \$50 million over a tenyear period to support basic research carried out in a new Department of Molecular Biology. All the research would be under the control of MGH and all research results could be freely published after a 30-day preview by the company, but Hoechst would have first refusal to license patentable results.

Both MGH and Hoechst insist that this arrangement is compatible with existing academic practice, that they have gone to great lengths to avoid any possible conflicts of interest or undue secrecy, and indeed that the terms of the agreement might act as a model for other universities seeking research support from the private sector.

Mr Gore, however, says that his concerns are endorsed by a report he commissioned from the General Accounting Office, the investigative arm of Congress, which pointed out ways in which the agreement might conflict with the patent legislation passed last year. Under the current legislation, any patents arising from jointly

funded research would remain the property of the research institution, but the federal government would be permitted free use of the patent, and would also be able to reclaim control of the patent rights. However, MGH acting director general Dr Joseph Martin insisted that a clear distinction would be made between research supported by the federal government and that financed by Hoechst.

Mr Gore remains unconvinced. He argues that maintaining a clear separation between separately-funded research projects is "simply a fiction" and promises that, even if his amendment to the patent legislation is dropped, he will be keeping a close eye on the MGH/Hoechst and other similar agreements, to protect what he describes as a massive public investment in recombinant DNA research. An official in the legislative office of NIH said last Friday that he felt the concern raised by the General Accounting Office; about jointly funded research "is certainly a problem that is not non-existent, although it does not currently appear very prevalent". A delegation from NIH will be visiting MGH next week to discuss the impact of the new patent legislation on future arrangements for federally funded research at the **David Dickson** 

# Science in France

# **Democratic** union

Grenoble

How far can democracy go? This question is emerging as one of those central to the new politics of science in France, and it was put to a remarkable test last week.

Professor Robert Tournier, the 47-yearold director of the renowned laboratory for very low temperatures at Grenoble, in the Rhônes-Alpes, announced some time ago to his colleagues that he wanted to resign the directorship to have more time for research in his own laboratory. Normally, the CNRS would take advice on a new director from the laboratory steering committee, and from the CNRS "parliament", the Comité National, and then would merely announce an appointment. This time it has another factor to take into account. Internal advisory committees in the laboratory could not agree on their recommendation for a successor, and Fournier, as a good democrat and socialist, asked the whole laboratory, including technicians, to give their advice on two candidates.

The resulting "election" took place last week. It has no official significance, and was nearly a draw. But the trades unions (their favoured candidate having won) are treating the event as a clear selection of director, and have written to the Paris headquarters of the Centre National de la Recherche Scientifique, to which the laboratory belongs, to say so.

As it happens, the narrowly-elected

candidate — a personable 39-year-old physicist called Daniel Thoulouze - is also likely to be the recommendation of the relevant section of the Comité National, so there may be no conflict. But the CNRS directorate is put in an awkward position whatever the result. If it selects Thoulouze, it will appear to approve of the grass-roots election of laboratory directors - which it wants to avoid. Yet if it selects another, it will appear to confirm the fears of the more radical scientists and the strong trades union movement in French science that, despite a socialist government, the selection of laboratory directors - who have great power over their laboratories will remain closed and centralized.

In the event, the CNRS may be forced to ask Tournier to continue. The new CNRS director-general, Jean-Jacques Payan, is not against elections in principle; but he says they should be undertaken only "in a very precise framework", meaning that the electorate should be appropriate to the category of post. But Payan is under great pressure from the grass roots, the technicians and the younger researchers, for a more democratic way of appointing directors, and he will certainly have to give in to some extent. As Tournier himself said this week, the question is whether the CNRS is forced into a system where directors must conform to majority opinion in a laboratory, or a system where the directors can be independent, but must subsequently seek to bring the whole laboratory behind them.

Meanwhile the unions of Grenoble, which have enjoyed a large degree of democracy (or at least, consultation), since 1968, are determined to be "serious" about the election. The candidates were grilled in debates, and their scientific and general laboratory policy examined, they said. The unions' objective is that the laboratory should continue to do good science, and they insist that that requires the director to have good relations with his staff, down to the lowest technician.

And to some extent, this policy is reflected at the Ministry of Research and Technology in Paris, which gave Payan his job at the CNRS. The strong feeling there is that science is more and more a collective exercise — and that democracy and efficiency go together. But on the other hand, they also feel at the ministry that too much democracy leads to "turbulence", a position which would seem to be close to Payan's own (which is perhaps not surprising, for the minister for science, Jean-Pierre Chevènement, and Payan have been close colleagues for a decade.)

In the end, the issue is going to be how far Chevenement is prepared to travel with the unions — and particularly the communist-affiliate CGT, which is strong at Grenoble. The CGT secretary here said last week that he and his union were watching and waiting. And if Chevenement does not come up to their expectations, he promises a struggle.

Robert Walgate

# What price IIASA?

Washington

The Vienna-based International Institute for Applied Systems Analysis (IIASA) has now been informed officially that the United States will be withdrawing its support for the institute from the beginning of 1983 (see *Nature* 3 December, p.390). This gives IIASA some breathing space in which to seek ways of keeping the United States involved — even if its contribution is severely reduced.

At present the United States and the Soviet Union together provide about half of IIASA's \$10 million annual budget, and the IIASA council is now looking at ways to reassess the dues from each of the member nations. At present the United States's \$2.5 million contribution comes from the National Science Foundation and is channelled through the National Academy of Sciences, and one possibility is that the money might be raised from other federal agencies. Private foundations are also being approached but so far all offers for support have been well below current levels.

Whether the United States will come back remains an open question. Founded in the early 1970s as a symbol of detente, IIASA has provided a useful window for both East and West on economic and social conditions on the other side — for example information about energy resources. But the institute has failed to stem doubts about the true academic value of its work.

# Pakistan's space ambitions

# A military option?

Bangalore

Pakistan looks set to embark upon an ambitious programme of space research with clear hints that the spur is the prospect of military applications in the long term. Dr Salim Mahamood, chairman of Pakistan's Space and Upper Atmospheric Research Commission (SUPARCO), while unveiling the details of a 10-year national space programme in Islamabad recently, said that Pakistan did not want to be left behind in the space race, and that his country is studying in detail the configuration of a satellite which "can serve strategic purposes by taking pictures of military installations, army movements and acting as control, command and communication bases"

The setting up of SUPARCO earlier this year, with President Zia at its head, is said to have given fresh impetus to the hitherto slow-moving Pakistani space programme which is currently concerned mainly with launching sounding rockets from a base on the outskirts of Karachi. Dr Mahamood

claims that Pakistan is on the way to developing a communications satellite that "would be launched with the aid of either a European or an American rocket".

Since the successful flight test of India's SLV-3 rocket in July 1980, there have been fears in Pakistan that India might use experience gained with SLV-3 to build a strategic missile. Indeed, in November 1979 an Indian parliamentary committee was told that within six months of a political decision, SLV-3 could be modified into a medium-range ballistic missile. But the Indian Space Department stresses that military objectives are beyond the purview of the Indian space programme which is directed at "harnessing space for socio-economic development".

There is concern too that with the launch of the Bhaskara II satellite, India is developing the ability not only to survey the land for natural resources but also to carry out military surveillance over Pakistan.

Dr Mahamood claims that over the next five years, Pakistan will attempt to test a space launch vehicle of its own. The controversial deal between Pakistan and the West German private enterprise space agency OTRAG seems to be in obeyance. It is claimed that Colonel Gadaffi, OTRAG's host in Libya, had contacted Pakistan with an offer of OTRAG's technology.

How true is the rumour of a link between OTRAG and Pakistan is not known but some strategic analysts say that OTRAG could provide about 2,000 qualified space technologists badly needed to bolster Pakistan's space research efforts.

Meanwhile, Pakistan is negotiating with the US National Aeronautics and Space Administration for the setting up of a \$10 million ground station near Islamabad to receive earth resources data from the Landsat remote sensing satellite.

# India's space programme

# Now for real

New Delhi

India entered a new phase in its development of a series of satellites for remote-sensing applications with the successful launching of its experimental satellite Bhaskara II, into a circular Earth orbit from the Soviet Union on 20 November. India's space programme for the 1980s includes as one of its two chief goals a major survey of natural resources. The other task is the development of space-based communications system. The first operational satellite, the National Satellite 1A will be launched in April 1982.

The 440-kilogramme Bhaskara II is an improved version of Bhaskara I, which went out of action, after 26 months, in August. Modifications to the camera system should eliminate the "corona discharge" which caused the breakdown of one of the two television cameras aboard Bhaskar I for a few months. And an extra

frequency has been added to its radiometer for more accurate measurements of atmospheric water content, a key factor in the satellite's subsidiary role of weather forecasting. The satellite also carries indigenously developed solar power cells for space qualification tests.

The next step after Bhaskara II will be the 600-kilogramme Indian Remote Sensing Satellite I (IRS I). A memorandum of understanding has been signed with the Soviet Union for launching it in 1986.

But India now has to face the prospect of a much more expensive space programme than in the past, since Bhaskara II marks the end of free launch vehicle and rocket booster facilities provided by the Soviet Union since the launch of the first Indian satellite in 1975.

Indian scientists are working on indigenous launch vehicles as alternatives, although experiments with the SLV-3 launch vehicle have so far achieved only qualified success. Nothing daunted, the Indian Space Research Organization is developing the Augmented Satellite Launch Vehicle (ASLV), based on SLV-3, which can put a 150-kilogramme satellites into space. India also plans to develop a polar satellite launch vehicle by 1986–87 to launch 600-kilogramme satellites into subsynchronous polar orbit 500 to 100 kilometres from the Earth. Sunil Saraf

# European environment

# One log-jam ends

Brussels

The Council of EEC Environmental Ministers which met in Brussels on 3 December was remarkably successful, with agreement being reached on several previously contentious issues.

The directive regulating discharges into the aquatic environment of mercury from the chlor-alkali industry was adopted. Attempts to push through the mercury directive and the "drins" directive (regulating aldrin, dieldrin and endrins) foundered on the dispute over whether quality objectives (favoured by the British) or limit values (preferred on the continent) should be used to assess the maximum permitted level of pollution discharged into water from an industrial plant. The ministers have now agreed on a clause requiring the latest technology to be used when building new plants.

The haggling over the Seveso directive on the prevention of major industrial accidents also ended at the meeting. The new French government has toned down its objections to the clause on the consultation of countries across the frontier from new plants. The consultations will now take place on a bilateral basis — without the involvement of the European Commission as originally proposed. Although the directive does not cover nuclear installations, the same consultation procedure is at the centre of a dispute between France and

# Electronic intrigue

Palo Alto

In probably the largest theft of semiconductor devices ever, \$2.7 million worth of integrated circuits disappeared over Thanksgiving weekend from Monolithic Memories Inc., a "Silicon Valley" company.

About 498,000 chips of two types were stolen. One kind, a programmable array, PAL, embodies circuits that provide a logic function in a wide range of computer products including video games, industrial equipment and computers used by the military. The second type, FIFO, is used to input data at one speed into computers and take it out at another.

About \$20 million worth of advanced computer chips disappear each year into a national and international underworld electronics trade. Integrated circuits are smaller than a fingernail, hard to identify and can sell for \$100 apiece. Many stolen chips are smuggled out of the United States into Eastern Europe. President Reagan's embargo on allowing Communist countries to buy high technology equipment provides a good market. Other chips are sold to pay narcotics dealers.

In 1979, an employee at INTEL stole 10,000 microcomputer devices worth \$1 million. They passed through blackmarket distributors in West Germany and eventually arrived at Siemens, a West German computer manufacturer. This robbery was traced when Siemens told INTEL that the untested chips were faulty. That the intensive electronic and human security at Monolithic Memories was bypassed suggests that in this case also the thief was an employee: the company is offering a reward of \$50,000 for information leading to an Charlotte K. Beyers arrest

Belgium. The French government intends to build power stations at Chooz, a few kilometres from the Belgian border.

Agreement was reached on a technical proposal to exchange data on sampling and monitoring levels of atmospheric pollution. However, the directive on safety levels for lead in air must wait until a communally acceptable method of monitoring atmospheric pollution is found.

Broad agreement was reached on the European Commission's third environmental action programme and its proposed policy to give environmental considerations greater weight when determining other EEC policies. Finally, despite much discussion, there was no decision to implement the Washington Convention—the EEC regulation on the trade in endangered species is, in fact, reported to be much tougher than the convention.

Jasper Becker

# Animal welfare

# Promise delayed

The new European legislation to protect laboratory animals seems to be in the hands of legislative snails. Optimists had expected agreement on the draft of a Council of Europe convention on "the protection of animals used for experimental purposes" last May. But the deadline passed, and the hope now is for agreement in March 1982.

Discussions have been under way since 1978, when the Council of Europe appointed an expert committee to draft model legislation. But the experts have so far failed to agree among themselves. Their latest disagreements relate to the "pain condition" that if an animal suffers severe and enduring pain, the experiment must stop and the animal be killed; the use of animals for more than one experiment; and the experimental procedures which should be included in the statistics on animal experiments.

Most of the representatives from the council's 21 member states object to the lack of provision for exemption from the pain condition in the latest draft. The exception is Britain, which wrote the draft when it took over chairmanship of the committee in April 1980. Britain argues that its own legislation, which includes the pain condition without exemption, has worked well since it was enacted in 1929.

Approval of the convention is also being held up by West Germany's objection to a clause which permits an animal used in one painful experiment to be used again. Most other countries accept the clause, some less willingly than others. A further stumbling block relates to whether animals used as controls, for example, should be included in statistics on animal experiments. Sweden believes that they should, but most other countries think their inclusion would push up the apparent number of experiments unncessarily.

The aim is to resolve these differences before the next annual meeting of the expert committee in March. When agreement is reached, however, a council of ministers will have to approve the draft before it can be laid before individual states for signature and ratification. Because ratification is a lengthy process, the convention is unlikely to come into force for several years.

Meanwhile, the European animal welfare lobby, increasingly vociferous, is asking for tighter controls than those in the latest draft. The Council of Europe's parliamentary assembly, which has no power but which can be influential, has agreed to discuss the lobby's demands and consider recommending changes to the terms of reference of the expert committee. If the assembly decides to recommend changes and the council of ministers agrees to implement them, the convention could be delayed indefinitely or even killed.

That, however, is unlikely. Most states

are eager for a convention as soon as possible, if only to head off the animal lobby's more extreme demands. Some, such as the United Kingdom, have already delayed national legislation pending a convention. Britain's Conservative government now has little more than two years in which to fulfill its last election promise to update the Cruelty to Animals Act of 1876. Two recent private members' bills to do just that have already come to grief. Judy Redfearn

# French reorganization

# Sector structure

Grenoble

Jean-Pierre Chevènement, Minister for Science and Technology in France, has finally decided on the structure and organization of his ministry. He has reaccumulated all the instruments and organizations of science and technology policy — dispersed since de Gaulle last had a major science ministry — and sorted them into a new structure.

The Délégation-Générale à la Recherche Scientifique et Technique, which acted as the relatively small office of the previous science minister, is to be disbanded and its staff re-absorbed. The same fate awaits the Délégation à l'Innovation et à la Technologie (which previously worked within the Ministry of Industry).

The new structure is claimed to be something midway between the highly dispersed "Rothschild" system of the United Kingdom in which individual ministries have control of large sums of research money which they can spend with research councils broadly as they wish, and the highly centralized German system; but the Chevènement structure is on the face of it considerably closer to the German than the British model.

The ministry will be divided into three sectors (plus the cabinet of personal advisers, which will be extended with the addition of a section to evaluate the progrees of his policies). There will be a "Direction de la Politique Générale", which, broadly speaking, will administer basic science through the "grands organisms" (the Centre National de la Recherche etc); a "Direction du Développement Scientifique et Technique et de l'Innovation" which will actively promote contacts between science and industry and mastermind the scientific renovation of the French economy (the matter closest to Chevenement's heart); and a high-flying "Mission Scientifique et Technique". This body, headed by Yves Farges, a one-time solid-state physicist and the principal advocate for a European synchrotron radiation source, will act as a kind of interface between the other two sectors and the minister himself.

The staff of the ministry at present numbers some 250. By the time the changes are complete — and the ministry has moved to a new location on the Montagne Ste-

Geneviève (the old site of the Ecole Polytechnique) the staff will probably have grown to 400.

Robert Walgate

# Scientific fraud

# In Bristol now

A further case of falsification in the scientific literature has come to light. The following letter has been received from Dr M. J. Purves of the Department of Physiology at the University of Bristol:

SIR — I very much regret to have to report that data published in the preceedings of the 28th International Congress of Physiological Sciences (Purves, M.J. 1981 Cerebral Blood Flow and Metabolism in the Sheep Fetus. Advances in Physiological Sciences 9: 199; 126. Pergamon, Oxford & Adademiai Kiado, Budapest) are false. I must also emphasize that none of my colleagues was involved in the preparation of this paper and the responsibility was mine alone.

Bristol, UK

M.J. PURVES

Dr Purves, a reader at the University of Bristol, resigned his post with effect from 1 November after an internal investigation.

The paper concerned describes the use of recently developed techniques for investigating the function of the mammalian (sheep) brain in utero. The article describes the use of 5-deoxyglucose as an index of metabolic activity in central nervous metabolism. One of the objectives of the study was to demonstrate that 5-deoxyglucose (not metabolized in the usual way) is taken up more slowly by the fetal mammalian brain during periods when the embryo is asleep.

The University of Bristol seems to have acted quickly since some of Dr Purves's junior colleagues drew attention to the irreproducible features of his published paper earlier in the year. An agreed announcement of the circumstances was delayed for family reasons. Dr Purves said earlier this week that the falsifications consist of the data published. His senior colleagues say that they cannot understand why such a talented person, well-supported by the Wellcome Foundation and the Public Health Services, should have followed such a course.

# Erratum

Nature must apologise to one or other (or both) of Sir Andrew Huxley (President of the Royal Society) and Professor T.R.E. Southwood that the latter's photograph appeared last week in place of the former's. The Royal Society's anniversary celebrations this year appear to have been especially prone to accident — the President of the Fellowship of Engineering, half-way through an impassioned speech on the importance of engineering, referred to the present President's predecessor-but-one, Dr.A.L. Hodgkin, as Professor Hodgkinson.

# Primitive life in France

Paris

The life and times of Europe's earliest inhabitants form the focus of a new exhibition at the Musée de l'Homme in Paris. The exhibition, which opened on 9 December and will run until April 1983, illustrates major advances in human development over more than a million years of European prehistory.

Evidence of human presence beginning with what are reputed to be the oldest stone tools in Europe is traced up to the appearance of fully evolved Neanderthals some 125,000 years ago, Remains from more than 100 sites in 13 European countries are on view, combined with replica living floors and two reconstructions of palaeolithic shelters.

The main advance portrayed in the exhibition, according to Professor Henry de Lumley, exhibition organizer and director of the Laboratory of Prehistory and the museum, is the domestication of fire in Europe some 400,000 years ago. By 300,000 years ago distinct cultures throughout Europe possessed knowledge of fire, were making various tool assemblages, living in organized encampments and hunting in groups.

By this time too, early Europeans had apparently begun to construct more elaborate living shelters with several distinct areas. The remains of two such living floors from sites excavated by Professor de Lumley provide the basis for the striking hypothetical recreations of a hut from Terra Amata and a cave shelter at Le Lazeret (both near Nice in France).

The Terra Amata hut is built from wood poles and pine branches on a replica rocky Mediterranean shore and is based on remains dated at about 380,000 years ago. The Le Lazaret cave shelter suggests an even more comfortable lifestyle by about 130,000 years ago.

Specialists may well debate the interpretation of the stones, bones, dates and reconstructions in this exhibition, but all visitors will go away with a lasting impression of how prehistorians recreate the past and what daily life might have been like for Europe's earliest inhabitants.

Richard Dreiman

# CORRESPONI

# Psychological slip

SIR - Reviewing H.B. Gibson's biography of Hans Eysenck (Nature 5 November, p.44) P.E. Bryant writes: "He (Eysenck), more than anyone, shaped the development of clinical psychology in this country;

This statement may be misleading to a readership as diverse as Nature's. In this context the term "clinical psychology" is used, or perhaps linguistically corrupted, to signify the application of behaviouristic or learning theories to the treatment of psychological disorders. It does not refer to the application of psychological theories collectively to the treatment of such disorders, which is the rational inference.

It may well be the case that Evsenck has shaped the development of behaviouristic clinical psychology in this country. However, it would clearly be incorrect to suggest that he has had much influence on the development of certain other principal approaches to clinical psychology such as psychoanalysis.

This duality of meaning is a potential source of considerable confusion, but one which can be simply obviated by qualifying the specific school of clinical psychology referred to.

GEORGE FIELDMAN

Department of Physiology, Chelsea College, London SW3

# **Species difference**

SIR - There is a serious misunderstanding which is impeding any resolution to the current debate on macroevolution. Recent analysts of the fossil record report a pattern which they claim "strongly supports the notion that speciation is a qualitatively different phenomenon from gradual, intraspecific microevolutionary change"1. This is true. Others point out that the observed details of fossil history "do not force us to change our views on the genetic mechanisms of the origin of species"<sup>2</sup>. This is also true. The misunderstanding lies in the idea that they are referring to the same thing, for they are not. They are addressing speciation on two entirely different levels.

The model of evolution in contention is the 'punctuated equilibrium'' proposal of Eldredge and Gould<sup>3</sup>. Evolution at the specific level is seen as occurring in short rapid bursts followed by relatively long periods of evolutionary non-change or stasis. The words "short" and "long" are used in the context of geological time. That is, morphological changes associated with the transition from an old species to a new one may occur on the order of 103 to 104 years, which is recorded as an instant in most fossil assemblages. Those who experiment on the evolutionary genetics of living organisms are quite correct in maintaining that this is more than enough time for classical selection mechanisms to have conceivably produced the observed changes. This much is clear to proponents of punctuated equilibrium as well. Why then the call for qualitatively new explanations?

The mechanisms depicting "how" new

species arise have in the past been considered explanations of "why" they develop as well. New species are classically described as being the logical result of long, slow, continuous selective pressure. This continual change is the view of phyletic gradualism. If, however, the prevailing pattern is one of stable equilibrium only punctuated with brief periods of evolutionary change then the mechanism of that change does not tell the whole story. The phenomenon of stasis, not the sudden appearance of new species, is the true source of the conflict with the traditional evolutionary school of thought.

Matters are not reconciled by appealing to selective pressures varying dramatically over time. The environment is dynamic and in a constant state of flux. While some periods may be characterized by a less stable climate than others, there are always marginal environments and isolated communities within which evolution can work. In addition the fossil record does not support the contention that novel stable species arise and replace parental populations only at times of the most extraordinary environmental instability. That is not to say that new species do not arise at times of climatic shifts, but other shifts of equal magnitude may not result in the establishment of new species while novel forms may invade from a marginal locale and become dominant at times of overall relative environmental tranquillity. Thus classical Darwinian theory does not provide an explanation for the punctuated pattern of speciation now emerging from the fossil

The models of population genetics may be perfectly adequate at the fine level of how new genetic entities are formed but they do not address questions at the grosser level of the overall patterns. New qualitatively different schemes are therefore needed. Conversely, while theories of a qualitatively different sort are indeed required by the recent reevaluations of the fossil record, the classical genetic mechanisms of speciation are nonetheless compatible with punctual equilibrium.

CLIFF TABIN

# Question of faiths

SIR - It is admirable to see scientists such as A.H. Batten and E.W. MacKie (Nature 30 July, p.402) come to the aid of the theory of evolution when they perceive that it is threatened by creationism. Such enthusiasm shows their dedication to rational thought. However, when in their eagerness they instead misrepresent its basic scientific tenets one has to wonder just whose side they are on.

Batten is quite correct in criticizing neo-Darwinian evolutionists for being overly dogmatic and thus in fact hastening the rise of the creationist movement. I cannot accept, however, the assertion that the theory of

evolution (that is, descent with modification) is the same as the theory of natural selection and, therefore, if chance mutations are found to be insufficient agents of phylogenetic change one must look for a purposive element to explain the observed hierarchical order in nature. This self-imposed dichotomy leads Batten to reject Popper's critical rationalism for Kuhn's paradigm of "normal science"

We are thus asked to console ourselves with knowing that if we wish to avoid a dogmatic assertion of evolution as a fact then it is necessary to see it as simply the best explanation we have at the moment. Since we must choose between neo-Darwinism and creationism there is not much chance of ever escaping the bonds of the existing paradigm. Batten's complacency with "normal science" and inability to consider other, natural causative agents of evolutionary change (of which the literature is full) only serve to weaken any intended appeal to reason. The arguments presented are also a serious misrepresentation of Popper's philosophy.

MacKie, on the other hand, has chosen to ignore Popper or any other proponent of the hypothetico-deductive method altogether (ignorance of this concept is difficult to believe) and take us almost 400 years into the past. The notion of science as inductive and mythology as deductive might have impressed Francis Bacon, but it has no place in modern thought. Someone should tell MacKie about David Hume. The only way out of the conundrum is to realize that science arises from grand, explanatory ideas, ranging from the metaphysical to the conjectural, and it is only after this initial synthesis that rigid testing is invoked. It is the creationists' uncritical appraisal of their own theories, in both testing procedures and methods of formulation, that marks their endeavours as unscientific. The inductive-deductive barrier has nothing to do

Both authors should learn to live with Popper's observation that rational thought is based on irrational faith in reason. I would add that evolutionary biology is similarly based on a faith that the natural causes we observe are indeed natural causes, and not the manifestations of a supernatural being. We are, then, faced with two faiths: those of rationality and irrationality. The former we can modify with critical argument, the latter we cannot. Yet, just because rationality arises from an irrational faith, we are not compelled to consider every aspiring scientific argument on equal grounds. It is not a case of the 'anything goes" attitude of relativism. I believe that is what MacKie worried about as egalitarianism. There should be no problem, since every hypothesis must prove itself in its explanatory power, testability and predictive success. Thus, as MacKie notes, the acceptance procedure for hypotheses must be shamelessly elitist (with respect to the particular hypothesis, not its proponent). Anything less would be uncritical and therefore unscientific. Faith per se is no threat to science; dogma and woolly-mindedness are.

RICHARD T. O'GRADY

Department of Zoology, University of British Columbia, Vancouver, Canada

105s-1) to account for both the NMR and ESR observations<sup>11,12</sup>

Reconstitution studies allow the experimentalist to manipulate the magnitude of the lipid-protein interaction by varying the relative concentrations of lipid and protein in the membrane. NMR studies of reconstituted membranes were described which indicate that as the protein concentration increases, moderate (about 20 per cent) decreases occur both in the average order (through deuterium order parameter measurements3) and in the rate of lipid chain motion (from T, relaxation measurements in proton1 and deuterium3 studies). An analysis of both the ESR spectral components shows that the rate of lipid chain motion for boundary and nonboundary lipids is decreased by the protein, when compared with the non-proteincontaining membrane. Unfortunately, no conclusive information on the amplitude of chain motion can be deduced from these spectra<sup>5</sup>. ESR and NMR observations therefore imply that the 'rough' protein interface both disorders the acyl chains interacting with it and restricts their motion. The magnitude of disordering or motional inhibition again depends on the spectroscopic method being used. These data appear consistent with the idea that proteins induce a rather specific perturbation on the membrane lipids, disordering and motional restriction, unlike the effect of temperature which decreases both the rate and amplitude (together often called 'fluidity') of acyl chain motion.

At the meeting, the relevance of dynamic lipid-protein interactions was questioned during a discussion period by the interjection "So what. . .?". During this and subsequent lively interchanges, it was suggested that lipids at the protein interface (1) may be important for efficient sealing of the bilayer to the protein, particularly vital in transport processes; (2) provide a motional buffer between the peptide backbone to the bulk membrane lipids; (3) sterically maintain at equilibrium the active conformation of a membranebound enzyme, which would require a fast motional interaction on the biochemical time scale defined by the catalytic turnover rate of  $10^2-10^3$ s<sup>-1</sup>; and (4) are able to contort and conform to the protein interface to solvate it in a way that minimizes the energy configuration within the whole membrane.

# New low temperature phases of H<sub>2</sub> and D<sub>2</sub> at ultrahigh pressure

from J.C. Raich and R.D. Etters

AT very low temperatures and atmospheric pressure the molecules in solid parahydrogen (p-H<sub>2</sub>) and orthodeuterium (o-D<sub>2</sub>) are in spherically symmetric rotational states. At a sufficiently high density it is expected that the interactions between the hydrogen molecules deform the average molecular density distributions so that the molecules spontaneously align in an orientationally ordered state. At this transition, the essentially free molecular rotations change to hindered rotations or librations about equilibrium orientations. These equilibrium orientations depend on the crystal structure of the high pressure phases which probably differ from the hexagonal close-packed low pressure structure. This rotation-libration transition in the hydrogens was first predicted by Raich and Etters1 using a mean field theory. Subsequently mean field calculations<sup>2</sup> and Monte Carlo simulations<sup>3</sup> have supported the first-order nature of the transitions as well as the approximate density dependence. These theories predict critical pressures at roughly 75 kbar for o-D, and 270 kbar for p-H, using an extrapolated equation of state4.

Recent improvements in high pressure techniques, made possible by the development of diamond anvil cells, have renewed interest in the rotation-libration transition and the resulting prediction of new low temperature, ultrahigh pressure, orientationally ordered phases of the solid hydrogens. Indirect evidence of such a transition in hydrogen has recently been reported from the pressure dependence of Raman measurements of the H-H vibrational stretching band  $Q_1(1)$  in hydrogen by Sharma, Mao and Bell4. The notion that changes in the molecular state of solid hydrogen begin to occur at approximately 200 kbar is supported by the flattening of the curve of the frequency shift  $\Delta\nu[Q_1(1)]$ versus pressure which begins to occur at 200 kbar. The decrease in the half-width of  $Q_1(1)$  at about 175 kbar is taken as additional evidence for a lessening of molecular rotation. The further flattening of  $\Delta\nu[Q_1(1)]$  at higher pressures can be interpreted as an indication that molecular rotation has ceased for pressures exceeding 375 kbar. Sharma et al.4 also observed that bands attributed to molecular rotation become diffuse and disappear well below 375 kbar at 298K. However, to attribute the observed changes in the vibrational mode to changes in the rotational motion is only one of several possible explanations. Another possibility might be a pressureinduced change in the electronic charge distribution of the molecule.

Recently, Lagendijk and Silvera<sup>5</sup> have

studied the rotation-libration transition, taking a different theoretical approach. They investigated the predicted behaviour of the collective rotational excitations in the solid as a function of pressure, and found that increasing the density of the solid leads to a softening of the collective rotational excitations with rotational quantum number J = 2. The excitation energy of these J = 2 rotons approaches zero at the X boundary point of the Brillouin zone of the face-centred cubic structure for which the calculations were performed. The existence of this roton instability requires a symmetry breaking of the orientational ground state with J=0. resulting in an ordered structure in which the orientational alignment occurs along the <111> directions of the face-centred cubic lattice. This approach predicts roughly the same transition densities as the earlier mean field treatments. On the other hand, recent Monte Carlo calculations by Aviram, Goshen and Thieberger, using the full anisotropic interaction between H, molecules, seem to predict transition densities which are about 60 per cent higher than the mean field densities6

Direct experimental evidence of the existence of a new high pressure phase of o-D, and the precursor of a similar phase of p-H<sub>2</sub> has recently been reported by Silvera and Wijngaarden using Raman scattering which has proved to be a very effective probe of the solid hydrogens. In the low pressure hexagonal close-packed phase, the Raman transitions of interest are three distinct  $J = 0 \rightarrow J = 2$  transitions. In the predicted high pressure phase, the crystal structure is probably different, with the result that the corresponding rotational excitation spectrum will be changed significantly. In o-D, at about 150 kbar, the J = 2 rotons begin to broaden and turn down in frequency. Between 200 and 278 kbar the roton spectrum coalesces into a single broad rotational band. Above 278 kbar the rotational band splits abruptly. These changes are accompanied by a sharp shift of the  $v = 0 \rightarrow v = 1$  or  $Q_1(0)$  vibrational frequency. The same change in behaviour is observed when the temperature is lowered below the critical temperature. These changes are considered to be the manifestation of a phase transition to an ordered phase at a temperature T = 5K and pressures  $p \ge 278$ ± 5 kbar in o-D2. Although no strong characteristic of a first-order transition was observed, it was not possible to rule out a

simultaneous hexagonal close-packed to face-centred cubic structural change analogous to the case of the zero-pressure o-H<sub>2</sub> and p-D<sub>2</sub> orientational transition.

 $\ln p - H_2$  for p > 500 kbar, the solid appears to be approaching the region where a similar phase transition might occur. However, higher densities seem still to be required. It is likely, however, that the rotation-libration transition in p-H, will occur before the metal-insulator transition.

The observed transition pressures, 278 kbar for o-D2 and in excess of 500 kbar for p-H<sub>2</sub>, are much larger than the theoretical predictions. Whether this difference is due to the approximations made in the various theoretical approaches, or to an inaccurate representation of the intermolecular potential, remains to be elucidated. In particular, the use of asymptotic forms for the anisotropic contributions to the H,-H, interaction potential at high pressures should be questioned seriously. A comparison of the results of Silvera and Wijngaarden8 with those of Sharma, Mao and Bell may be difficult as the latter started with fluid hydrogen at room

temperature and the former with p-H, at only a few degrees Kelvin.

# New pathways for chlorinated dioxins

from Alistair Hay

UNTIL recently many would have argued that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) — a toxic contaminant produced in the manufacture of 2,4,5-trichlorophenol — was not metabolized in animals. The chemical seemed to require no metabolic activation to make it more toxic and did not appear to be metabolized before excretion.

But times have changed, and so has the evidence. It is still true that TCDD is active in its own right, but it is equally clear that some metabolism of the chemical occurs in animals. Poiger and Schlatter (Nature 281, 706; 1979) were the first to report that TCDD was hydroxylated in the rat. Others are reporting similar findings. At a recent workshop\* R.A. Neal (US Chemical Industry Institute of Toxicology) reported that Golden Syrian hampster hepatocytes will metabolize TCDD in vitro, producing a pattern of metabolites similar to those excreted in the bile and urine of the animal.

The faeces (bile) is the major route of excretion in the rat, hampster and mouse. The TCDD which is retained in tissues after administration appears to be unmetabolized. For the small amount of the chemical which is metabolized - generally of the order of one per cent — the process appears to begin with hydroxylation to phenols. The hydroxyl groups, Neal suggests, are then converted to. glucuronides prior to excretion.

Before this reaction scheme can be proved, the metabolites will have to be positively identified. H. Poiger and H.R. Buser (University of Zurich and Swiss Federal Research Station respectively) have identified metabolites in the bile of the rat and the dog which enables them to suggest that in these two animals, TCDD is metabolized by the reaction scheme shown in Fig.1. They claim that metabolism of TCDD is a process of detoxification. Extracting the metabolites from the bile of dogs and testing for toxicity in the guinea pig shows them to be at least 100 times less toxic than the TCDD itself.

According to S. Safe (Texas A & M University) there are common features in the metabolism of polychlorinated dibenzodioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and polychlorinated biphenyls (PCBs). With all these chemicals the rate of metabolism decreases as the degree of chlorination increases; and the major metabolites formed are phenolic compounds which are generally less toxic than their parent hydrocarbon precursors.

When aromatic hydrocarbons reach a certain size and lipophilicity it seems that they are poorly retained in the body. There is considerable species variation in the metabolism of different isomers of these compounds and lipid stores have a major role in the regulation. H.B. Matthews (NIEHS, Research Triangle Park, US) reported that animals eventually reach a state of dynamic equilibrium with adipose and other tissues playing their part in sustaining blood TCDD concentrations. Should the blood concentration fall, dioxin will move out of other tissues and back into

the blood in sufficient amounts to restore the equilibrium. The process, says Matthews, is not rapid, but occurs over a period of days, perhaps even as long as a

When animals are starved TCDD is mobilized from adipose tissue and this could lead to blood dioxin levels reaching concentrations which ultimately prove toxic. Fortunately, in human subjects this situation is unlikely to occur. The body burden for TCDD in humans is thought to be low. But low as blood levels of this chemical are, it is becoming clear that it can stay around for a long time.

C. Rappe (University of Umea, Sweden) reported that pentachlorodibenzofurans could be detected in the liver of a young Japanese man — at a level of 1.2 ng g-1 -12 years after he was exposed to the chemicals. The PCDFs were present as contaminants in PCBs which affected a batch of cooking oil in Japan in 1968. The

RAT DOG TCDD Dechlorinated metabolite not yet determined Оон (OH), Fig. 1 Metabolism of TCDD in the rat and dog.

<sup>\*</sup>The 'International Symposium on Chlorinated Dioxins and Related Compounds' was held at the Sheraton National Hotel, Arlington, Virginia, 25-29 October 1981.

victims affected by this oil are known as the 'Yusho I' cases. A similar 'Yusho II' event occurred in Taiwan in 1979.

It is currently standard practice to assess exposure to chlorophenols by measuring the levels of these chemicals in urine. Rappe, however, suggests that blood measurement of the PCDF and PCDD contaminants present in the chlorinated phenols is a superior method. Urine concentrations of chlorinated phenols fall rapidly to undetectable levels in a very short time whereas PCDDs and PCDFs can be detected in blood years after exposure. Although the significance of TCDD levels in blood is not yet clear, many believe that it is important to have more of these measurements to try and relate blood levels to clinical symptoms.

It is a pity this information is not available now for assessing the carcinogenic risk from TCDD. Reports from Sweden (Hardell and Sandstrom Br. J. Cancer 39, 711: 1979) suggest that forestry workers exposed to chlorinated phenols and the herbicide 2,4,5-T have a sixfold higher incidence of soft tissue sarcomas. A repeat of the investigation by one of the Swedish scientists to take account of some criticisms of the earlier study confirms the initial findings (Hardell Scand. J. Work envir. Hlth 7, 119; 1981).

However, studies conducted in other countries have so far failed to confirm Hardell's reports. A cohort of herbicide applicators in Finland exposed to phenoxy herbicides for at least two weeks between 1955 and 1971 have been monitored since 1972. The incidence of tumours in this group is no higher than would be expected and no cases of soft tissue sarcoma have been observed. Similarly, preliminary findings from a study in New Zealand, reported by A.H. Smith (Wellington Hospital), in which soft tissue sarcoma cases were compared with patients with other forms of cancer showed that the individual's place of work bore no relationship to the type of tumour seen.

The different findings from the various studies are disturbing. So much so that a workshop study group on the health implications of TCDD exposure concluded that it was a matter of urgency that additional studies be done to determine whether there is indeed a causal relationship between soft tissue sarcoma and exposure to phenoxy herbicides such as 2,4,5-T.

Experimental design of the epidemiological studies may have some bearing on the different results obtained. If so, it is important that new studies should take account of this. There is general agreement that all the studies performed to assess the carcinogenic risk from exposure to TCDD and phenoxy herbicides were well designed. However, it is felt that some studies may have bias which has so far gone unrecognized. If this is the case it will be some time yet before there is unequivocal evidence about the health risk from exposure to 2,4,5-T.

# Parasites affect behaviour of mice

from F.E.G. Cox

PARASTTIC WORMS are ubiquitous in small mammals, even in many laboratory colonies, and are almost invariably ignored in behavioural studies. Two recent investigations indicate, however, that they may markedly influence both the acquisition of dominance and general exploratory behaviour of mice.

When male mice are reared in isolation and then put together fighting occurs and a hierarchy of dominance is established with one dominant male. This simple procedure has allowed an Australian scientist, W.J. Freeland, to investigate the effects of nematode infections on the behaviour of mice!. Using groups of two infected and one uninfected mice, he found that those given 50 or 150 larvae of Nematospiroides dubius became dominant as often as uninfected ones but those given 250 larvae became dominant less frequently than would be expected. Once dominance in uninfected mice was established, however, a subsequent infection with 250 larvae did not lead to its loss. Freeland argues that, as dominance may be related to mating success, infected mice are at a reproductive disadvantage and that females mating with uninfected or lightly infected males protect themselves and their offspring from infection and also select males with genes for resistance to

Even though these results are convincing and the conclusions self-evident, they are subject to a number of reservations. First, the number of mice used in each trial, three, was small, although 20-30 trials were used for each level of larval infestation; a more satisfactory procedure would have been to use 6-10 mice. Second, the numbers of worms that brought about behavioural changes were relatively large. In natural infections the majority of mice carry small numbers of worms and very few carry large numbers2 and 250 is more than would normally be expected. The reasoning also fails to take into account the true nature of nematode infections in mice in the wild for the female is as likely to become infected from another male as from her mate as there is no permanent pair-bonding and, as rodent territories are not absolute, males tend to roam over large areas.

The suggestion that female mice might effectively select for genes for resistance is also open to question. Although the importance of genetic factors in resistance to nematodes in general and to N. dubius in particular is well documented3, individual animals acquire their initial infections with large and small numbers of worms purely by the

F.E.G. Cox is Professor of Zoology at King's College, London.

chance ingestion of infective stages and only later mount an immune response; so in primary infections, like the ones described, the female would be selecting for luck rather than resistance. Furthermore, more active males range further and thus have more opportunities to become infected; this is well known for ectoparasites such as ticks4 and is presumably also true for worms of various kinds.

The second set of experiments were carried out in the United States at the State University of New York and Cornell<sup>5</sup>. In these experiments, mice were infected with the dog nematode Toxocora canis. The larvae of this worm cause considerable damage by burrowing about the body of abnormal hosts and may cause blindness in children. In mice, the larvae may enter the nervous system and brain. The American workers infected mice with T. cants and subjected them to a number of behavioural tests to assess such activities as exploratory behaviour, areas traversed, avoidance reactions and spatial discrimination in mazes. The various tests were carried out sequentially over a period of 115 days and in all tests infected mice did less well than infected ones. The authors conclude that T. canis infection reduces exploratory activity, learning and motor coordination. These results are easier to understand than those of the dominance experiments for the mice infected with T. can's were all found to have parasites in the brain at autopsy, but a direct correlation between brain damage and behavioural changes has not yet been established.

These two sets of experiments taken together, however, do suggest that parasites can modify the behaviour of rodents and although this is well known in other hosts the gross behavioural changes are usually brought about by physical damage such as is caused when a parasite lodges in the eye or brain or occupies a considerable amount of the body cavity. The interactions between parasite and host may, however, be more subtle than this and parasites in the gut or kidney may affect the odours produced by the host or may even affect its hormone balance. It is likely that parasites will be increasingly implicated in alterations in host behaviour; however the nature of these changes will not be resolved by the use of simple behavioural experiments but will have to follow the advances being made in our understanding of the underlying mechanisms of animal behaviour. # Useful tropical legumes

from Robert M. May

AMONG the many potential applications of research on recombinant DNA that are exciting commercial enthusiasm is the hope that cereal and other crops may be genetically engineered to fix their own nitrogen. This is a consummation devoutly to be wished, because current trends in the cost of energy are making nitrogenous fertilizers extremely expensive for peasant farmers. At the same time, however, there appear to be many plants in the family Leguminosae that are greatly underexploited; some are extensively used in one locality but unheard of elsewhere, while others are virtually unknown but have particular attributes that suggest they could be developed into major crops. The legumes provide their own nitrogenous fertilizer through bacteria that live in nodules on the roots of the plant, where the bacteria convert nitrogen gas from the air into soluble compounds the plant can absorb and use. Although a few other plant families include species with this ability, legumes produce the bulk of biologically fixed nitrogen. Even today, the total nitrogen added to the world's soil by cultivated leguminous crops exceeds that added by fertilizers.

Leguminous plants are found throughout the world (including a few aquatic legumes), but the greatest variety is in the tropics and subtropics. There are approximately 650 genera and 18,000 species of Leguminosae, which makes them the third largest family of flowering plants (after the Compositae and the Orchidaceae). The family is divided into three subfamilies: the Caesalpinioideae, comprising about 2,800 species which are mainly trees of the tropical savannas and forests of Africa, South America and Asia; the Mimosoideae, again comprising about 2,800 species, which are mostly small trees and shrubs of semi-arid tropical and subtropical regions of Africa, North and South America, and Australia (Acacia species are prominent in this category); and the Papilionoideae, comprising around 12,000 species, which are mainly herbs and are distributed worldwide. Legumes can most easily be recognized by the pods they bear; these pods come in an enormous variety of sizes and shapes, from one not much bigger than a pinhead to one the size of a tennis ball, and they contain from one to several dozen seeds.

A recent study (Tropical Legumes: Resources for the Future, National Academy of Sciences, Washington, DC, 1981), emphasizes that "Of the thousands of known legume species, less than 20 are used extensively today". Cultivation is most commonly for the seeds (called beans, grain legumes, or 'pulses'), which rank

second only to cereals as a source of human and other animal food. Nutritionally, leguminous seeds are typically two to three times richer in protein than are cereals. Before the advent of the potato in Europe, beans constituted much of the diet of the poorer classes. Today, they remain a major food in Latin America, on the Indian subcontinent (especially lentils and chickpeas) and in the Far East (especially soybeans). Greater emphasis on pulses, in contrast to the 'Green Revolution's' emphasis on cereals, could do much to alleviate the chronic protein deficiency found in many developing countries.

The NAS report notes many promising pulses that stand in need of further research. The virtues of the Winged Bean have been extolled earlier (Nature 266; 590, 1977). The Bambara Groundnut is an African pulse which seems to constitute a complete food: although "its seeds have less oil and protein than peanuts, they do have more carbohydrates and make a well balanced food with a calorific value equal to that of a high-quality cereal grain. .. it can thrive in arid inferior soils where peanuts fail, it resists pests and diseases, and, if managed well, can give high yields". Another example is the Moth Bean, which is "an exceptionally hardy South Asian legume that thrives in hot, dry, tropical conditions, [producing] nutritious seeds and green pods, leafy forage for hay or pasture, and a soilbuilding 'living mulch' to complement orchard crops and to protect and improve fallow land. . . . It is likely to prove very useful in extending agriculture production into marginal regions - especially those bordering tropical arid zones". An interesting candidate for a cash crop is the Yeeb, from the Horn of Africa, which flourishes in tropical arid zones and produces seeds with taste akin to macadamia and pistachio nuts.

In earlier centuries, when natural dyes were the only way to colour fabrics, legumes played a key part in the history of Western exploration and colonial development. The blue dye indigo, extracted from small leguminous shrubs of the genus *Indigofera*, was a major product of India, traded eastwards to China and westwards to Europe. More valued than spices, it was a major reason for establishing Portuguese, Dutch and British colonies in India. In South America, the small leguminous tree *Caesalpinia echinata* vielded a wine-red essentially identical to

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

bresil (from Caesalpinia sappan), a dye that Europe had been importing from Asia for centuries. This dye soon became the most important export from the new land to Portugal, whence the merchants became known as bresilieros, and the region as Brasil or Brazil.

Turning from the past to the future, the NAS report systematically lists many kinds of uses to which legumes may be put, beyond the relatively familiar pulses.

Native tribes in several rural areas of the world eat tubers harvested from wild or cultivated legumes. Most of the species so used have not been subjected to scientific research, but a few that have been analysed show a remarkably high protein content (sometimes several times higher than the root crops in conventional use in the tropics). The NAS report urges the study of these little known root crops, with a view to improving and disseminating the most productive and nutritious ones.

There are several interesting fruits that could be more widely exploited. For instance. Mediterranean peoples have for millenia enjoyed the sugar-rich, mealy pulp of carob pods. "The handsome, droughttolerant carob tree deserves more research and widespread exploitation in semi-arid areas, for in addition to pulp it provides a chocolate substitute, high-protein flour and an industrial gum, as well as shade, beautification, erosion control and forage." Although in common use for centuries, the tamarind remains largely unimproved and little cultivated; up to half the mass of a tamarind pod is sour-sweet pulp, which is used in refreshing drinks (and in Worcestershire sauce). The honeylocust can be easily grown from seed, suckers, or cuttings, and grows fairly fast to produce giant pods from the fourth or fifth year. The sweet, succulent pulp of the pods is relished by humans and other animals. As I have one in the backyard, I learn with mixed feelings that it is one of the hardiest, most adaptable and most generally useful fodder trees known, but that care is needed in new locations as it can form dense thickets and become a pest (as it has in Queensland).

Too often, woody plants are overlooked in programmes of research for improved forage in tropical regions. Yet, as the NAS panel notes, browse shrubs and trees can complement herbaceous pasture species and can be crucial to the survival of animals during droughts (when shallow-rooted species often shrivel to straw). Emphasizing that many species undoubtedly await discovery and exploitation, the NAS study focuses on the thorny, flat-topped Acacia tortilis bush (one of the most drought-tolerant trees of semi-arid areas of Africa and the Middle East, and a great soil stabilizer) and on other species of Acacia and Prosopis (both of which are drought-resistant and well adapted to light, sandy soils).

Among many fast growing trees of potential commercial significance is the

Leucaena leucocephala (itself the subject of a separate book, Leucaena leucocephala: New Forage and Tree Crop for the Tropics, NAS, 1977). Resembling a mimosa, the tree can grow 65 feet tall and 16 inches thick in five years (roughly six times the rate of growth of an oak), giving wood suitable for paper pulp, furniture or building. Bushy varieties of the species help prevent soil erosion, while providing a nitrogenous fertilizer or a cattle feed rich in protein. Acacia auriculiformis, a robust and little known tree from New Guinea, can grow with exceptional vigour on problem soils such as eroding hillslopes, mining spoil, laterite and sand, as well as in highly acid and alkaline sites. More generally, the NAS report looks at other fast growing trees (especially of Acacia and Albizia species) and concludes that "many woody legumes are pioneer species that colonize newly cleared sites. To outdo the competition, they grow fast and are very precocious and vigorous trees that nodulate well. With the desperate need for reforestation, erosion control, firewood, and paper, as well as other wood products in developing countries, many such leguminous trees are worth widespread testing".

The rosewoods — classic furniture woods renowned for their gorgeous colours, beautiful grain and exceptional technical properties — come from species of *Dalbergia*, slowly growing leguminous trees found throughout the tropical regions of the world. Most species are being harvested to commercial extinction, and silvicultural research has been so neglected that in most cases it just is not known whether

the trees can be cultivated. The fascinating properties of several other slowly growing, 'luxury timber' trees are discussed in the NAS report. Here the problems of lack of information are compounded by the commercial reality that the 'discounted present value' of such slowly growing trees is relatively low, making their cultivation economically unattractive (see *Nature* 263; 91, 1976).

Last, but not least, legumes have given us many of the world's most exquisite flowering plants: wisteria, laburnam, poinciana, orchid trees, cock's comb coral tree, the raintree and many others. The NAS book lists and, better, illustrates the other beautiful leguminous species that should be far more widely known and more extensively planted, before they become extinct

# Small minded — the characterization of interplanetary dust by electron microscopy

from Colin Pillinger

In recent years, the extraterrestrial sample community has been made increasingly aware that a third category of material, besides meteorites and lunar rocks, is available for laboratory study. Samples of interplanetary dust may be collected in the Earth's stratosphere by appropriately equipped high flying aircraft. The grains, known as 'Brownlee particles' after Don Brownlee (of the University of Washington, and more lately the California Institute of Technology), who championed the cause of the collection programme, are now being collected in a programme coordinated by NASA from the Johnson Space Center.

Collecting cosmic dust is not a new pastime. Almost a hundred years ago the Challenger expedition recovered spherules of presumed cosmic origin from the slowly accumulating Pacific sediments1. Brownlee himself obtained copious quantities of extraterrestrial material from this source with his so-called 'cosmic muck rake', a magnetic device trailed behind a ship and capable of processing thousands of tonnes of sediment per day. Similar attempts have been made to find extraterrestrial debris in Arctic and Antarctic snow and a variety of other sediments. Perhaps the first report of micrometeorite debris can be attributed to an occurrence of 'Cryoconite' (Icedust) in Greenland ice2 reported in 1872.

Particle collection at high altitudes is possible because the braking effect of the terrestrial atmosphere is able to concentrate the incoming dust flux to around  $10^{-3}$  particles per m<sup>3</sup>. The frictional heating caused by deceleration depends on the size of the particle and its emmisivity. Very small grains (<10  $\mu$ m) do not reach anything like the melting point of the constituent material as they have been

slowed to terminal velocity from a speed of 25 km s<sup>-1</sup> at an altitude of 100 km (ref.3). Probably half the grains of size <10  $\mu$ m and with density  $\sim$  1 will not have been heated to greater than 550°C for more than two seconde<sup>4</sup>

That comparatively mild thermal history has meant that very flimsy low-density grains whose structures are often described as 'porous', 'reentrant' or even 'fairy castle' have survived for collection. That they are truly extraterrestrial is shown by rare gas contents and isotope abundance patterns which can only have been produced by exposure to the solar wind<sup>5,6</sup>. Solar flare particle tracks which might also provide evidence of space exposure have not, however, been found, suggesting that either some annealing took place during entry or the lifetime of interplanetary dust grains at 1 AU is much shorter than anticinated6

Availability of a special sample is one thing, participation in its study is another. Among the few who can sensibly contribute to the analysis of Brownlee particles is the group at the McDonnell Center for Space Sciences of Washington University, St Louis. Since 1976, this group, particularly P. Fraundorf, has been examining 11 particles in the size range  $4-15 \mu m$  by analytical techniques involving electron microscopy. Perhaps this five year effort and future studies on the same 11 grains are put in perspective by Fraundorf's analogy that a 5 µm grain to an electron microscopist is the same as a three ton hand specimen to a field geologist.

Fraundorf's efforts are now directed towards the chemical and mineralogical

Colin Pillinger is in the Department of Earth Sciences, University of Cambridge.

taxonomy of interplanetary dust particles and in a recent paper<sup>7</sup> he attempts to emphasize their differences, not only from known meteorite classes, but from each other. He has now become so familiar with his grains that each has acquired a name, some of which describe the characters of the specimens. Thus, 'Blowup' 'exploded' on crushing into hundreds of silicate fragments of wide-ranging composition each coated with some low atomic number material. 'Lost and Found' was predominantly a crystalline coarse-grained aggregate which was difficult to handle because of electrostatic charging.

Electron microprobe and single grain neutron activation studies have already shown8 that Brownlee particles have compositions which may be called 'chondritic', that is, similar to chondritic meteorites and relatively unfractionated compared with solar abundances. Fraundorf has looked more deeply into the compositional variations. One hundred and fifty analyses from regions as small as 10-15 cm3 from his 11 grains give average elemental abundance ratios which would be described as chondritic but on inter- and intra-grain scale the variations are extensive. In the case of meteorites, element abundance ratios can fairly uniquely define the class to which a sample belongs — none of the eleven grains could be assigned to a distinct chondritic group with any certainty.

Plotted on the standard Urey-Craig plot (reduced iron + sulphide/Si versus oxidized iron/Si), interplanetary dust particles (IDPs) fall in the region ascribed to the most reduced H, L and E chrondrites, samples which often show some degree of metamorphism. None of Fraundorf's eleven grains plots with the oxidized carbonaceous chondrites,

samples generally thought to be the most primitive (least metamorphosed) meteorites, even though numerous arguments exist to show that IDPs are relatively unmetamorphosed and probably contain per cent quantities of carbonaceous phases (low atomic number material).

It would be easy to see how incoming IDPs were oxidized during entry but not reduced; the overall oxidation state of IDPs must reflect their formation in a highly reduced region of the primitive solar nebula. Fraundorf points out from his mineralogical studies that some of the finegrained magnetite decoration on crystal surfaces might be due to atmospheric heating, but could just as easily fit characteristics predicted by core/mantle models for interstellar grains.

Before Fraundorf's studies, only X-ray powder diffraction had been used to recognize minerals in whole IDPs (ref.9). Now as a result of both single- and polycrystal electron diffraction studies, coupled with dark and bright field imaging and consideration of concurrent chemical analysis data, magnetite, pyroxene, olivine, pyrohotite, taenite and cohenite (the latter as a possible deposition product from a reducing gas phase) have all been identified. Perhaps just as important is that amorphous zones of a particular chemistry (such as S/Fe > 2) have been observed. One surprise is the absence of hydrated silicates, again distinguishing IDPs from the matrix material in carbonaceous chondrites. The possibility that water was lost by exposure in space or atmospheric entry cannot be discounted but the evidence seems more and more that Brownlee particles are distinct from known meteorite classes and really are a third category of extraterrestrial sample.

It is hoped that soon many other investigators will become small minded and accept the challenge of Brownlee particles. The full characterization of primitive materials and their taxonomic classification is a necessity to our understanding of the early Solar System. It is still largely supposition that IDPs are derived from cometary sources but the indirect evidence to this origin continues to grow. Just the conjectured availability of cometary dust alone should mean a tremendous crossfertilization between the laboratory-bound analysts and the spacecraft experimenters who hope to receive data from the ESA Giotto mission to Halley in 1986.

# Clues for the origin of cosmic rays

from Peter Meyer

DURING the 1960s and early 1970s it became possible to measure the elemental composition of the cosmic radiation in fine detail. This achievement constituted a major breakthrough towards recognizing the elusive origin of the high energy particles that pervade the Galaxy. In particular, it was found that elements over the entire range of the periodic system are present in the cosmic radiation. that the relative abundance ratios of the cosmic ray elements are strikingly similar to those found in the elements that make up the Solar System. Hoyle first made the suggestion, now generally accepted, that the chemical elements heavier than lithium are produced by nucleosynthesis in the interiors of stars. It seems clear that the cosmic ray particles cannot be primordial, but rather must have been part of stellar material before their acceleration.

The crucial questions remaining to be answered concern the identification of the sites of origin and of the acceleration mechanisms responsible for the high energy particles. From the point of view of energy alone, it is clear that a powerful particle accelerator must be available. The cosmic ray population must be replenished, on the average, every ten million years, which is the currently accepted value of the mean storage time of the particles in the Galaxy before escape. This population is known to have existed with an intensity similar to that now observed throughout the lifetime of the Solar System, that is, about 4,500 million years. Supernova explosions are the most energetic known phenomenon in the galaxy, and were therefore long suspected to be responsible for the origin of cosmic ray and possibly to imprint characteristic

Peter Meyer is Professor of Physics at the Enrico Fermi Institute and Department of Physics, University of Chicago.

abundance distributions on the ejected

Major theoretical work has led to a deeper understanding of various nucleosynthesis processes and in attempts to describe the elemental and isotopic composition of the Solar System, the end products from hydrostatic and explosive nucleosynthesis were investigated. Explosive syntheses are expected to occur on a short time scale in conditions similar to those observed in the supernova phenomenon. Hence, the deviations of cosmic ray elemental and isotopic compositions from the Solar System or interstellar matter abundance distributions provide information that reveals the origin of the particles.

Two recent publications Astrophysical Journal Letters (1 August 1981)address this question in two different ways. One paper deals with the isotopic abundance of several elements of low atomic number, the other with the elemental abundances of nuclei with atomic number between 26 and 40 (Fe to Zr)2. The abundance distribution of the elements lying between helium and nickel in atomic number is not a particularly sensitive discriminator between the nucleosynthesis processes forming the cosmic ray elements, but the isotopic composition is. The discovery of an 'anomaly', that is, a deviation from Solar System abundance, in the isotopic composition of the element neon was therefore received with great excitement3-8.

The most accurate results were obtained from two high-resolution experiments carried out on the spacecraft ISEE-3, for the Caltech group<sup>5</sup> and for the Berkeley group<sup>1,8</sup>. They present additional, new values for the abundance ratios <sup>22</sup>Ne/<sup>20</sup>Ne,  $^{21}$ Ne/ $^{20}$ Ne,  $^{25}$ Mg/ $^{24}$ Mg,  $^{26}$ Mg/ $^{24}$ Mg, <sup>29</sup>Si/<sup>28</sup>Si and <sup>30</sup>Si/<sup>28</sup>Si. It is claimed that all these isotopic ratios show enhancements of the neutron-rich isotopes over Solar

# 100 YEARS AGO

THE conduct of competitive examinations in China seems to be farther from perfection than might be expected in the case of such an ancient institution. The Peking Gazette contains a memorial from one of the censors complaining that the matsheds which are erected at the entrance to the examination hall in the capital to issue tickets of admission to competitors are frequently overturned by the rush of applicants, that an unseemly crowding and snatching of tickets from the officials take place, and that candidates break the rule prohibiting them from leaving the compartments in which they are isolated during the examination. They are allowed, he says, to fetch their food themselves (examinations in China last from thirty-six hours to three days at a stretch) from the kitchens, and they meet and converse freely. Prepared essays, the memorialist fears, are passed in from outside during these hours by the student's friends. Again, when the lists of successful candidates are posted up, a tumultuous crowd assembles outside the gates; bands of the unsuccessful ones obstruct the progress of the chief examiner, employing threats and entreaties to prevail on him to alter the lists.

System abundances. This enhancement amounts to a factor of about 1.6 except for the ratio of 4.1 measured for <sup>22</sup>Ne/<sup>20</sup>Ne. It is not yet understood why the Ne isotopes show a larger anomaly; a theoretical model by Arnett<sup>9</sup>, extended to the special case of these cosmic ray isotopes by Woosley and Weaver<sup>10</sup>, would predict all the ratios to be of the same order.

There is no doubt that the isotopic ratios for the above cosmic ray nuclides differ from the standard Solar System values. The critical reviewer of this work remains concerned that the standard Solar System values are always quoted without errors, which are obviously difficult to estimate. A most interesting comparison is made by Wiedenbeck and Greiner with recent spectroscopic determinations of the silicon isotopes in interstellar clouds<sup>11</sup>. In some interstellar clouds an enhancement of the neutron-rich isotopes 29Si and 30Si is observed which is not dissimilar to that seen in the galactic cosmic rays. If such observations turn out to be representative for the interstellar medium, the anomalous isotopic composition of the cosmic rays remains compatible with their source being pre-existing interstellar material which itself carries those anomalies.

The second sensitive indicator for the nature of the cosmic ray sources is the chemical abundance distribution of the very rare ultraheavy elements with atomic number byond that of the iron/nickel group. Attemps to measure that abundance distribution date back to the late 1960s, only a few years after the discovery of ultraheavy elements in the cosmic radiation. The early measurements pointed towards an enhancement of elements produced by rapid nucleosynthesis. The work by both Binns et al.2, carried out on the spacecraft HEAO-3, and Fowler et al. 16, on ARIEL-6, has much improved charge resolution. Binns et al. conclude that, within the charge range of Z from 26 to 40, the HEAO-3 results are inconsistent with a cosmic ray source that is dominated by r-process nucleosynthesis, but quite

consistent with an elemental abundance distribution similar to that of Solar System material. A crucial element ratio supporting this conclusion is the Se/Sr abundance ratio, found to be about ten times that expected from the r-process.

Clearly, the recent work on isotopic anomalies as well as on the abundance distribution of superheavy elements in the cosmic rays is consistent with the interpretation that the source of the particles may be the interstellar medium. It is important to note that these papers represent interim results, that are expected to be improved upon, and that in both directions of research much remains to be done. Several crucial isotopic ratios  $(^{34}S/^{32}S, ^{54}Fe/^{56}Fe, ^{58}Fe/^{56}Fe)$  must be

determined accurately with instruments having higher sensitivity than exists at present; this work should go hand in hand with new attempts to determine the corresponding isotopic abundances in the interstellar medium. The potentially very revealing elemental distribution of elements with Z > 40 must be measured accurately. The Pt/Pb ratio and abundance of the actinides are particularly crucial in identifying the origin of the particles. Some time in the future measurements of isotopic composition may include the ultraheavies; this would provide a powerful tool not only for determining the sources of cosmic rays, but also for understanding the contemporary interstellar medium.

# Middle atmosphere dynamics

from John Gregory

MUCH of our understanding of the dynamics of the middle atmosphere 1-9 comes from data gathered in the mid-sixties by rocket techniques and by meteor radars. The techniques each had their particular limitations and left the mesosphere and lower thermosphere (60-100 km above the Earth's surface) as the least known regions of the atmosphere. In the 1972 Cospar International Reference Atmosphere2, for example, data were insufficient to assemble a latitude-season cross-section of meridional winds, 60-120 km above the Earth's surface, while the zonal crosssection was incomplete for the higher latitudes and altitudes. This situation provided the impetus to set up a coordinated program of international scientific research, the Middle Atmosphere Program (MAP).

In the last decade, two new techniques have provided additional data. First, satellite-borne radiometers 10,11 have improved global coverage of the stratosphere and lower mesosphere, to 80 km, notably with respect to the large-scale temperature structure and its perturbation by planetary waves and stratospheric warmings. Weighting factors broaden with altitude and result in decreasing altitude discrimination and this, coupled with low temporal resolution, means that data for the study of motions such as tides and gravity waves may not be readily available from these techniques. The derivation of geostrophic winds from temperatures, after inversion of radiances, requires knowledge of pressure fields at a lower boundary, such as is available from balloon and rocket sondes.

The second technique comprises ground-based radar, in several variants, to which may be allied lidar. The oldest form of radar measurement of winds12, in which

a moving diffraction pattern at ground level is sampled at spaced antennae, has been applied to MF partial radiowave reflections<sup>13-15</sup> from irregularities in electron density. Examples of the wind field determined by fully automated version of this method are shown in Figs 1 and 2. A later form16-20, in which Doppler measurements of winds are made at VHF, utilizes reflections from electrons in the mesosphere, and aerosols in the troposphere and lower stratosphere. In the region 30-60 km, irregularities in neutral density provide some scattering, but extremely sensitive radars are required to detect it. These two variants of radar, once conceived as differing in principle, have been shown<sup>21</sup> to be based on the same scattering irregularities. Thomson scattering from electrons at UHF can be processed to yield winds, 60-100 km<sup>22</sup>. Lidars<sup>23,24</sup> are now being employed to derive winds and density profiles, 30-80 km. The altitude resolution of the radar techniques is from 0.2 to 3 km, and is thus adequate for studies of gravity waves and tides. VHF and UHF radars are advantageous for turbulence studies.

Available techniques are already providing data for MAP projects in dynamics, in particular, a coordinated study of the behaviour of the middle atmosphere in winter (MP-1; Chairman, K. Labitzke) and equatorial wave dynamics (MP-2; Chairman, I. Hirota). Study groups have identified observational requirements for dynamical problems for example, the role of tides, gravity waves and turbulence in respect to momentum and energy budgets (Study Group 3;

The wind field in the mesosphere and lower thermosphere, as determined by spaced-antenna radar, operating at 2.22 MHz, in a fully-automated mode, at Saskatoon, 52N, 107W. The zonal flow, Fig. 1, is in good agreement with European results at similar latitudes, but the meridional flow, Fig. 2, shows a poleward component below 80 km in summer, contrary to model calculations.

Chairman, M.A. Geller), also the role of gravity waves and turbulence in respect to transport of minor constituents (Study Group 2; chairman J.D. Mahlman).

Techniques are potentially available for the majority of probable programmes, with two major exceptions. Gravity waves and turbulence are at present amenable to study only by ground-based and rocket techniques so the determination of their global characteristics seems a goal that is unlikely to be met. Also, measurements of mean vertical speeds, which range from cm per second in the troposphere to m per second in the lower thermosphere, are not yet practicable. The two related techniques, Doppler and spaced-antenna radar, are in principle capable of doing so, but there are economic as well as technical limitations. Finally, it may be noted that satellite measurements of winds by Doppler optical and microwave techniques are under development, but mainly due to spacecraft scheduling, are unlikely to produce data for about a decade.

Models of global circulation have been developed from basic equations of motion and knowledge of radiation fluxes and constituent concentrations3-9. A second approach has been to calculate the meridional circulation, including vertical motion, from observed radiance fields25. So far, only zonal mean motion has been modelled. Most models are able to reproduce the major features of zonal mean flow in the stratosphere and mesosphere, for example, the winter eastward and summer westward flow (see Fig. 1). A major difficulty which seems to have been encountered in nearly all models is the development of excessive Coriolis torques from meridional flow, the latter being derived from the requirement that vertical motion compensate for observed departure from radiative equilibrium, for example, the cold mesopause in summer. In consequence, computed zonal speeds are generally much in excess of those observed, and modellers have resorted to imposing arbitrary damping. Since planetary waves have now been excluded from the list of possible sinks of momentum in the summer mesosphere<sup>26</sup>, opinion currently favours tides and gravity waves as the damping mechanisms. It appears that before significant advances in modelling mean flow can be made, observational and theoretical studies of tides and gravity waves, together with their interaction with mean flow, must progress.

Much of the theoretical study and modelling of specific dynamical features, for example, the quasi-biennial and stratospheric oscillation<sup>27</sup> warmings<sup>28,29</sup>, as well as the global circulation, preceded MAP, and would undoubtedly have proceeded independently of it. The purpose of MAP is to facilitate such work, and this is possible in two ways. First, desirable observational programs are indentified. The space and time scales appropriate to each dynamical process are determined. Thus, for example, attention has been drawn to the relative lack of observations in the tropical upper mesosphere. Member nations of The Inter-Union Special Committee on Solar Terrestrial Physics (SCOSTEP) are encouraged to determine what contribution they can make to global observational programmes, or what work they may specifically attempt in their territory. Thus European nations have made special studies of winter middle atmosphere conditions, and are planning more.

Second, the systematic compilation of data is to be attempted. This is intended to permit the assembly of a dynamic climatology of the middle atmosphere, initially between 30 and 60 km, and as data become available, between 60 and 120 km. In addition, the data are intended to form a source for incorporation into models, and a reference for comparison. In particular, such data will, it is hoped, serve to guide aeronomers concerning the transport of trace constituents, in respect to which an 'eddy diffusion coefficient' is currently utilized. It is well appreciated that many of the aeronomic problems of the middle atmosphere, for example. concentration of water vapour in the summer mesosphere, or of electrons in the winter mesosphere cannot be determined by photochemical studies alone, and a major aim of MAP is to ally these latter to appropriate dynamical studies.

# The early Universe

# Edward W. Kolb\*† & Michael S. Turner\*\*

\*Theoretical Division, University of California, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

†Institute for Theoretical Physics, University of California, Santa Barbara, California 93106, USA

‡Astronomy and Astrophysics Center, University of Chicago, Chicago, Illinois 60637, USA

In the past few years one of the most exciting areas of research in physics has been the interdisciplinary field of cosmology and particle physics. The NSF's Institute for Theoretical Physics in Santa Barbara devoted a 6-month program and an intensive 1-week workshop to the subject. A brief review is given of both the workshop and this field which is attracting attention, in part, because the early Universe seems to be the only laboratory in which to study grand unification.

AT the Institute for Theoretical Physics (ITP) on the campus of the University of California at Santa Barbara, the NSF is trying a new approach for tackling problems in theoretical physics. The idea is to bring together for 6-months to 1-year periods people from all over the world who are working on similar problems, in the hope that their collective effort will be more productive than the sum of what the individuals could accomplish working separately. Usually several different workshops run concurrently, and so there is the possibility that connections between apparently disconnected areas of physics will be found.

From January to June 1981, a program was held on the early Universe, which focused on the close relationship between cosmology and particle physics. Simultaneously, there were related programs in the areas of quantum gravity and gauge field theories. Within the past 5 years there has been much exciting work and interesting developments in the interdisciplinary field of particle physics and cosmology. The primary tool of cosmologists has been the large telescope, but now they are interested in deep underground mine experiments built to detect proton decay, in experiments on mountain tops searching for rare cosmic ray events, in experiments performed at accelerators and reactors which are designed to detect axions and neutrino oscillations, in balloon flights looking for antiprotons, in high altitude U-2 flights which carry instruments to measure anisotropies in the 3 K microwave background, in low temperature searches for fractional charge states, in deep underwater muon and neutrino detectors, and even in a proposed monopole search at an iron-ore processing plant.

Traditionally, the large accelerator has been the primary tool of the particle physicist, however, they are now interested in reactor experiments, in deep underground mine experiments, in bulk matter searches for exotic particles left over from the big bang, in the cosmic abundance of helium and deuterium, in the distribution of galaxies, in the structure of the microwave background, and even in experiments designed to detect solar neutrinos. It is not uncommon to find as many cosmologists as particle physicists at a particle physics seminar and vice versa. The connection between the two disciplines is, of course, the big bang. In the early Universe temperatures as high as  $10^{32}$  K were reached, corresponding to average particle energies as high as 1019 GeV. The particles present and their interactions determined the early evolution of the Universe, and the type of relics that remain. Particle physicists are constantly seeking higher energies where the world appears simpler, and the early Universe seems to be the only laboratory with large enough energies (≥10<sup>14</sup> GeV) to study models of the unification of the strong, weak and electromagnetic forces. Cosmologists are asking particle physicists if neutrinos have small rest masses, and if the proton is unstable. If neutrinos have small rest masses they may determine the large-scale dynamics of the Universe; and if the proton is unstable, baryon number violating reactions may

explain why the Universe is predominantly matter, rather than having equal amounts of matter and antimatter. Conversely, particle physicists are asking cosmologists about the cosmic environmental impact of exotic particles which either cannot be produced at accelerators or would have escaped detection.

The culmination of the early Universe program at Santa Barbara was a week-long workshop which brought together experimental and theoretical high energy physicists, theoretical astrophysicists, astronomers and cosmologists. The workshop focused on many of the recent exciting developments and the important outstanding problems of common interest in both particle physics and cosmology. We shall now highlight some of the work presented at the meeting, and review the present status of the field of cosmology and particle physics.

# Standard big-bang model

It is now generally accepted, and supported by observations that the Universe began from a hot big bang (for review see refs 1-3). The evidence includes: the universal expansion or 'Hubble flow'; the 3K cosmic microwave background; the large abundance of D and  ${}^4\text{He}$ ; and on the theoretical side, the singularity theorems of Hawking and Penrose. In the homogeneous and isotropic Friedmann-Robertson-Walker (FRW) model, the scale factor of the Universe, R(t), is governed by

$$(\dot{R}/R)^2 = H^2 = 8\pi G\rho/3 + \Lambda/3 - k/R^2 \tag{1}$$

where  $\rho$  is the total energy density,  $\Lambda$  is a possible cosmological term, and k is the curvature signature, which when R(t) is appropriately scaled is 0 (open and flat), 1 (closed and positively curved), or -1 (open and negatively curved). The energy density of radiation  $\propto T^4 \propto R^{-4}$  as  $T \propto R^{-1}$ , and the energy density of matter  $\propto R^{-3}$ . For  $T \ge 10^5$  ( $\Omega h^2$ )K ( $t \le 3 \times 10^{10}$  s  $\Omega^{-2}$   $h^{-4}$ ), radiation dominates the energy density and the right-had side of equation (1), as it increases faster than the other two terms as  $R \to 0$  ( $\Omega$  is the present ratio of the energy density to the critical energy density, and the Hubble parameter H = 100h km s<sup>-1</sup> Mpc<sup>-1</sup>). During the radiation epoch, the age and temperature of the Universe are related by

$$t = \left(\frac{45}{16\pi^3 G}\right)^{1/2} g_*^{-1/2} T^{-2} = 2.41 \text{ } \mu \text{s } g_*^{-1/2} T_{\text{GeV}}^{-2}$$
 (2)

where  $g_*$  is the total number of degrees of freedom of all species which are ultrarelativistic (that is species with  $m \ll T$ ), and throughout units are used such that  $\hbar = c = k_{\rm B} = 1$ . For  $t \ge t_{\rm Planck} \sim 10^{-43}$  s, quantum corrections to general relativity should be small, and equations (1) and (2) should be valid. When T is much greater than the mass of a particle, that particle and its antiparticle are about as abundant as the photons. So for  $T \ge 10~{\rm GeV}$  ( $t \le 10^{-8}$  s), all the particles which we have produced at accelerators ( $e^\pm$ ,  $\mu^\pm$ ,  $\tau^\pm$ ,  $\nu\bar{\nu}$ , and all the quarks) were as abundant

as photons. Earlier than  $t \sim 10^{-12}$  s, average particle energies were greater than 1,000 GeV—the highest energies achieved at particle accelerators. At  $t = t_{\rm Planck}$ ,  $T \sim 10^{19}$  GeV. It is clear why the early Universe has been called the ultimate particle accelerator.

# Elementary particles and interactions

In the past decade or so much progress has been made in the understanding of fundamental particles and their interactions: the strong, weak, and electromagnetic forces (for review see ref. 4). There is now good evidence that the fundamental particles of nature are quarks-five different types are known to exist, and a sixth type is also believed to exist (u, d, c, s, b and t), and leptons—six different types are known (e<sup>-</sup>,  $\nu_e$ ,  $\mu^-$ ,  $\nu_\mu$ ,  $\tau^-$  and  $\nu_\tau$ ). Quarks and leptons apparently come in pairs: (u, d) and ( $\nu_e$ , e<sup>-</sup>); (c, s) and  $(\nu_{\mu}, \mu^{-})$ ; (t, b) and  $(\nu_{\tau}, \tau^{-})$ . Each quark also comes in three colours. It is now believed that each of the fundamental forces can be described by a gauge theory, in which the interactions are mediated by gauge bosons. Each gauge theory is distinguished by an invariance group, usually unitary (symbol U(n)) or special unitary (symbol SU(n)), whose elements are 'rotations' on an n-dimensional complex vector. Each gauge theory has its particular group (and value of n) which distinguishes it from all others: it has particular algebraic relations among its charges, and among the gauge fields that emanate from them, which are determined by the group—which thus determines the physical nature of the fields described.

For example, the gauge theory of electromagnetism is a U(1)theory, and the gauge field is the electromagnetic field whose particle representation is the photon. The colour force between quarks is described by an SU(3) gauge theory. The gauge fields are the colour fields, and their particle representations are called gluons. The strong forces between nucleons and other baryons and mesons are believed to be a residual effect of the colour force, analogous to van der Waals' forces. The weak and electromagnetic interactions can be described by one unified theory, the  $SU(2) \times U(1)$  gauge theory. (Here each element of the direct product gauge group is composed by taking the product of one element from U(1) and another from SU(2).) In this theory the gauge particles are the photon,  $W^{\pm}$  and Z bosons. Normally these bosons, like all primitive gauge bosons, would be massless and long range, but in the Weinberg-Salam model which uses the  $SU(2) \times U(1)$  gauge group an additional concept is introduced: that the vacuum is not empty but uniformly filled with certain scalar fields, the Higgs fields, which possess a subset of the charges of the gauge group and slow the propagation of-or give mass to-the corresponding subset of gauge bosons. Here these are taken to be W<sup>±</sup> and Z' are given masses of around 80 GeV. This process called 'spontaneous symmetry breaking' has a characteristic energy scale below which the gauge symmetry is broken (and the relevant gauge bosons get mass) and above which the full symmetry is restored (and all the gauge bosons are massless). (The usual analogy used for spontaneous symmetry breaking is ferromagnetism. Maxwell's equations are rotationally invariant; however, below the Curie temperature the rotational invariance of a ferromagnet is spontaneously broken when the magnetization chooses a specific direction.)

Encouraged by the success of the  $SU(2) \times U(1)$  unified gauge theory, particle theorists have speculated that all three forces are unified under one gauge group (not yet determined) which is spontaneously broken. In the simplest class of models, the breaking scale has been calculated to be  $\sim 10^{14}$  GeV (ref. 5). The unification of the three interactions requires new interactions, interactions which violate baryon and lepton number conservation. These two conservation laws were never very pleasing; unlike charge or energy and momentum conservation, these quantities do not couple to long-range forces.

The startling prediction of grand unified theories (GUTs) is the instability of the proton, with a lifetime of  $0(10^{30} \text{ yr})$ . At least five large underground experiments designed to detect proton decay are under construction, and several smaller experiments

are operating (for review see ref. 6). A Japanese-Indian collaboration in the Kolar Gold Fields has recently reported three candidate events for proton decay, translating into a proton lifetime of  $\sim 3 \times 10^{30}$  yr (ref. 7).

The simplest picture of unification predicts no new interactions between 300 GeV and  $10^{14}$  GeV; however, there very well may be new interactions yet to be discovered. There is, of course, the problem of also unifying gravity—'superunification'. Grand unification seems to occur ~4 orders of magnitude lower than the scale at which gravity should be as strong as the other forces (~ $10^{19}$  GeV), and it is hoped that gravity can be unified independently, at a later stage. At present, various efforts are being made to obtain a quantum theory of gravity, and even unify gravity (for example, supergravity theories).

In the gauge theory description the world becomes simpler at higher energies-full symmetry is restored, and the forces are predicted to become weaker, so that the Universe, during its earliest stages when particle number densities were as high as 1099 cm<sup>-3</sup>, can be treated as an ideal gas of weakly interacting point-like particles. Clearly the early Universe is the only laboratory in which the ultrahigh energies that particle physicists are now interested in were achieved. Unfortunately, this laboratory shut down over 1,000 Myr ago, so that one must search for fossils which remain from the earliest epochs. The fossil record to date includes: the existence of structure in the Universe (galaxies, clusters, and so on), the baryon-to-photon ratio  $\approx (3-5) \times 10^{-10}$ , the abundance of D and <sup>4</sup>He, and the 3K microwave background and its angular structure, the absence of a large cosmological term or curvature term (that is, both are less than, or of the order of the matter density term), the possible existence of fractionally charged states, and the absence of various exotic species that might have been present if various proposed particle physics theories were correct.

# Primordial nucleosynthesis

One of the great triumphs of the hot big-bang model is primordial nucleosynthesis (for review see ref. 8). During the period  $\sim 1-200$  s after the 'bang' when T was  $\sim 1-0.1$  MeV,  $\sim 25\%$  of the mass of the Universe was synthesized into <sup>4</sup>He, with lesser amounts of D, <sup>3</sup>He and <sup>7</sup>Li being produced. The nucleosynthetic yields depend on nuclear reaction rates which are measured in the lab,  $\eta$  (the ratio of nucleons to photons), and the expansion rate of the Universe which itself is determined by  $g_*$ , the number of effectively relativistic species present [see equation (2)]. By using the observed abundance of <sup>4</sup>He, which is the sum of the primordial and stellar produced <sup>4</sup>He, big-bang nucleosynthesis has been used as a very powerful probe of this early epoch. Specifically, one can set an upper limit to the number of light (<1 MeV) neutrino species, as they would have been present and contributed to  $g_*$  during this epoch. However, to do this, one needs a lower bound to  $\eta$ . If one assumes that baryons (and not, for example, neutrinos) dominate the mass of small groups of galaxies, then dynamical studies of these systems provide such a bound, and the limit of ≤4 neutriono species has been obtained. In quark-lepton symmetric theories this implies ≤8 quark flavours9

At the Santa Barbara workshop Steigman reported new work 10 which uses the D and 3He abundance to obtain a lower bound to  $\eta$ , and also results in the limit of  $\leq$ 4 neutrino species, independent of whether or not baryons dominate the mass of small groups of galaxies. Note that this lower bound is consistent with that obtained from studies of small groups of galaxies, and so is evidence that small groups are dominated by baryons. Studies of rich clusters of galaxies result in a much higher lower bound to  $\eta$ , indicating that they are not predominantly baryons, but perhaps neutrinos. In addition, when 4He is used to obtain an upper limit to  $\eta$ ,  $\eta$  is restricted to the range  $3-5\times10^{-10}$ , or  $\Omega_{\rm B} \cong (0.01-0.02)\ h^{-2}(T_{\gamma}/2.7\ {\rm K})^3$ . Thus, nucleons alone cannot close the Universe. With this new lower bound, the standard model makes the firm prediction that the primordial 4He production is 0.23-0.25. The primordial mass fraction of 4He must be less than the presently observed fraction of 4He. 4He

observations range from 0.23 to 0.32 with some of the values having stated errors as small as  $\pm 0.01$  or 0.02. The higher values can be accounted for by stellar production (and indeed usually involve systems with normal metal abundances, indicating that stellar processing has occurred). If the primordial mass fraction of <sup>4</sup>He is found to be less than 0.23, then the standard model is in trouble <sup>11</sup>.

If this should occur there are several alternatives: a cold big bang in which the 3 K background must be produced astrophysically  $^{12.13}$ ; perhaps some of the primordial D and  $^3$ He (or  $^4$ He) was destroyed by astrophysical processes; or a large lepton number might be hidden in the undetectable neutrino seas. In the standard model of primordial nucleosynthesis it is assumed that the lepton number-to-photon ratio, like  $\eta$ , is  $\ll 1$ . Reeves discussed primordial nucleosynthesis when the lepton number-to-photon ratio is of 0(1) (ref. 14). Relaxing the assumption that the lepton number is small allows much more freedom, and it is possible to explain simultaneously a low primordial  $^4$ He abundance, and the observed abundances of D and  $^3$ He. Although baryosynthesis usually results in lepton and baryon numbers of the same order of magnitude, one of us (E.W.K.) discussed a GUTs scenario which results in  $\eta \sim 10^{-10}$  and a large lepton number  $^{13}$ .

#### Baryosynthesis

Although the laws of physics are almost exactly matter-antimatter symmetrical at the microscopic level (the only exception is a small effect in the neutral kaon system), the Universe appears to be grossly asymmetrical. There is no evidence for the existence of appreciable amounts of antimatter in our Galaxy. If antimatter exists in the Universe in non-negligible amounts, then the size of matter or antimatter domains must be greater than the size of clusters of galaxies<sup>16</sup>. The matter asymmetry is usually quantified as the baryon number, or more exactly the baryon-to-photon ratio  $B = (n_b - n_5)/n_{\gamma} \cong \eta$ , where  $n_b$ ,  $n_5$ , and n, are, respectively, the number densities of baryons, antibaryons and photons. (For review of baryosynthesis, see refs 17, 18.) The Universe today has  $B = 3-5 \times 10^{-10}$ ; for  $t \le 10^{-6}$  s after the 'bang' ( $T \ge 1$  GeV), baryons and antibaryons were as abundant as photons, and this ratio then translated into a matter-antimatter fractional asymmetry of ~1 part in 1010. Perhaps the most exciting application of GUTs to cosmology is the possible explanation of the baryon asymmetry. Sakharov<sup>19</sup> discussed the conditions necessary for an initially symmetrical universe,  $n_b = n_b$ , to evolve into an asymmetrical universe,  $n_b \neq n_{\bar{b}}$ . The three ingredients outlined by Sakharov are: baryon number nonconserving interactions; C- and CP-violating interactions, that is, interactions which violate matter-antimatter symmetry; and a departure from thermal equilibrium. The necessity of baryon number violation and interactions that distinguish between particles and antiparticles (CP-violation) is clear. As the entropy of a system is a maximum when the baryon number vanishes, a departure from thermal equilibrium is also necessary for the microscopic interactions to produce the asymmetry.

In GUTs quarks and leptons are usually grouped together in a unified manner, and so there is a gauge equivalence between leptons and quarks. Physically, this gauge equivalence corresponds to interactions mediated by gauge bosons (which, of course, violate baryon number conservation). As C- and CP-violations are observed in the kaon system, it is not unreasonable to expect such violations to occur also in baryon number violating reactions. The expansion of the Universe can provide the final condition: if the expansion is rapid enough, then the temperature of the universe  $(T \sim R^{-1})$  changes too fast for particle interactions to maintain equilibrium. All three of these ingredients are incorporated into the out-of-equilibrium, drift and decay (British) model proposed by Weinberg and Wilczek<sup>20,21</sup>.

The generation of the baryon asymmetry has motivated many people to take the idea of unification seriously enough to study various grand unified models in detail. In fact, until proton decay is seen, the existence of a cosmological baryon asymmetry is the only "experimental" evidence for baryon number violation. Several detailed calculations of the generation of the baryon number were presented at the conference.

Although the standard scenario for the development of the baryon asymmetry has rapidly gained wide acceptance, there are still basic uncertainties in the model. One uncertainty involves the assumption of thermal equilibrium as an initial condition. The effect of non-equilibrium initial conditions was discussed by one of us (M.S.T.)<sup>22</sup> who showed that the magnitude of the asymmetry produced can be different if the Universe was not intially in a state of thermal equilibrium. Another uncertainty is the magnitude and type of CP-violation. It seems almost certain that the baryon asymmetry cannot be directly related to the CP-violation in the K°-K° system. Nanopoulos23 presented a model that related the CP-violation responsible for the baryon asymmetry to the neutron electric dipole moment, and not to the kaon system. (The electric dipole moment of the neutron is another possible manifestation of CP-violation.) The calculations suggest that the neutron electric dipole moment should be just smaller than the present upper bound.

Although many details need to be worked out, there is a feeling that a solution to the fundamental cosmological problem of the origin of the baryon asymmetry is at hand. A possible problem is the detection of low-energy cosmic ray antiprotons by Buffington et al.24 discussed at the conference by Gaisser. Although the antiprotons (p) detected are small in number (≈14) and small in proportion to the protons detected (p̄/p≈ 10<sup>-4</sup>), and although ps are expected to be produced as secondaries in high-energy cosmic ray collisions, the energy of the antiprotons detected are too low to be accounted for by standard galactic cosmic ray models. Several possible explanations were discussed at the workship: (1) The experiment is wrong. (2) The galactic models are grossly in error. (3) The ps were originally produced at high energies and then decelerated without annihilating. (4) Cosmic ray neutrons oscillate into antineutrons which then decay into antiprotons. (5) The antiprotons are primary cosmic rays originating from antigalaxies 23 . Although there was no consensus on the interpretation of the experiment, there was agreement that if the experiment is correct, the implications will be very significant.

#### Galaxy formation

On the largest scales (>10 Mpc) the Universe is quite smooth and homogeneous, while on small scales (\$10 Mpc) it is lumpy (nuclei, atoms, molecules, creatures, planets, stars, galaxies, clusters and superclusters). The large-scale smoothness, the uniformity of the microwave background, and the absence of a profusion of black holes are evidence that as early as recombination  $(T \sim 4,000 \text{ K}, t \sim 10^6 \text{ yr})$  the Universe could be described by an FRW model supplemented by small density perturbations. The concordance of the primordial nucleosynthesis calculations with the observed abundances of D and <sup>4</sup>He, probably indicates that this description was valid as early as  $\sim 1$  s after the 'bang'  $(T \sim 10^{10} \text{ K})$ . It is generally believed that small density fluctuations, present at recombination, after being freed from the pressure support provided by the radiation, collapsed due to their self-gravitational attraction and evolved into the structure we observe today. This is where the general consensus ends. The precise details of the growth of the density perturbations since recombination, their initial spectrum and origin are all areas of intense research and debate (for a review of galaxy formation, see ref. 26).

During the radiation dominated epoch  $(T > 10^5 \, \mathrm{K} \, \Omega h^2)$  density perturbations can be divided into two classes: isothermal and adiabatic. The subsequent development of structure is very different for these two types of initial fluctuations. Isothermal perturbations are characterized by uniform radiation temperature, with spatial variations in the beryon number-to-photon ratio. After recombination isothermal perturbations grow on all scales  $> 10^5 \, M_\odot \, (M_\odot = 1 \, \mathrm{solar \ mass} \simeq 2 \times 10^{33} \, \mathrm{g})$ . Structure forms on the smallest scales first, which then themselves cluster,

and so on in a hierarchical manner. Adiabatic fluctuations are characterized by spatial variations in the temperature, but constant baryon number-to-photon ratio. During recombination, fluctuations on scales  $\leq 10^{14} \, M_{\odot}$  are damped by photon diffusion, so that the first structures to form are  $10^{14} \, M_{\odot}$  pancake-like objects (which are now identified with superclusters), which subsequently hydrodynamically fragment into galaxies, and so on.

Two recent developments in particle physics and cosmology have had important implications for theories of galaxy formation: baryosynthesis and the possibility of non-zero neutrino masses in the range 10-100 eV. Shortly after the idea of baryosynthesis was first discussed it was shown that if the Universe was nearly FRW during the epoch of baryosynthesis, it was not possible to produce a baryon asymmetry and isothermal fluctuations simultaneously—thus favouring the adiabatic picture<sup>27</sup>. However, at the Santa Barbara workshop two groups reported that in a universe initially dominated by large-scale inhomogeneous shear, isothermal perturbations can be produced during baryosynthesis<sup>28,29</sup>.

The adiabatic picture predicts temperature fluctuations of  $0(10^{-3})$  in the microwave background on small angular scales  $(\theta \ge 10'')$ , which do not agree with the observations. Massive neutrinos may save the adiabatic hypothesis. Last year a Russian group reported evidence that the electron neutrino has a mass  $0(30 \, \text{eV})$  (ref. 30) (GUTs can very naturally accommodate such neutrino masses). A neutrino of mass  $\sim 3 \, \text{eV}$  would dominate the mass density of the Universe; a neutrino of mass  $\sim 100 \, \text{eV}$  would provide closure density. Bond and Szalay reported that when massive neutrinos are added to the adiabatic picture, smaller initial perturbations are needed, resulting in predicted microwave fluctuations which are smaller than the present observational upper limits  $^{31.32}$ .

Both laboratory experiments (neutrino masses, proton decay, and so on) and astrophysical observations (more precise measurements of both the large and small scale structure of the 3 K background, further studies of the distribution of galaxies, and so on) should have a great impact on theories of galaxy formation in the next few years. During the workshop, it was clear that this was already beginning to occur. Silk discussed how the recently observed quadrupole anisotropy in the 3 K background tightly constrains both the adiabatic and isothermal pictures<sup>33</sup>, and Davis reported on the recent observation of large holes in space (devoid of galaxies)<sup>34</sup>. These holes are most easily explained in the adiabatic theory, while the observed quadrupole asymmetry favours the isothermal theory.

#### Exotic relics from the big bang

As the energies explored by manmade machines (<1,000 GeV) are quite modest in terms of the energy scales of GUTs ( $\geq 10^{14}$  GeV), the early Universe is the only laboratory where physics at such energies can be studied. However, because this accelerator has not been in operation for  $\sim 10,000$  Myr, to study the physics of such high energies the observationalist must often search for fossil evidence although energies of up to  $10^{19}$  GeV were probably realized in the early stages of the hot big bang. One example that received a lot of attention at Santa Barbara is the search for relic supermassive magnetic monopoles.

Polyakov and 't Hooft<sup>35,36</sup> have shown that whenever a simple group (most of the gauge groups proposed for grand unification are simple groups) spontaneously breaks down to a group which contains a U(1) factor [for example, to the low energy symmetry group, SU(3)×SU(2)×U(1)] magnetic monopoles with a mass of order 100 times the symmetry breaking scale exist. These monopoles are topological objects associated with 'kinks' in the Higgs field (the Higgs mechanism is used to break the symmetry spontaneously). It is difficult to see how less than ~1 monopole per horizon volume would be created, as causality precludes straightening out the Higgs field on larger scales. (The horizon volume is the largest-sized region that could have communicated by light signals since the 'bang'.) The usual symmetry-breaking scheme of GUTs results in a predicted relic

monopole abundance of about one per nucleon<sup>37</sup>. As these monopoles have a mass of  $\sim 10^{16}\,\mathrm{GeV}~(\sim 10^{-8}\,\mathrm{g})$ , it is not surprising that such a present abundance can be ruled out by using our rather meagre knowledge of the present mass density of the Universe ( $\rho \leq 4 \times 10^{-29}\,\mathrm{g}\,\mathrm{cm}^{-3}$ , which corresponds to  $\Omega \leq 2$ ). A monopole abundance of one per nucleon would correspond to  $\Omega \cong 10^{14}$ .

This discrepancy between prediction and observation has been widely discussed. Possible solutions discussed at the workshop included mechanisms that would confine monopoles and antimonopoles in much the same way that quarks are confined in nucleons. In such schemes the confined monopoles and antimonopoles can annihilate to an acceptable level. Another possible solution is to keep the symmetry from being restored at high temperatures, as the monopoles are produced when the symmetry breaks. Finally, the most popular solution seems to be a hypothesis in which the universe supercools thereby delaying the GUT phase transition (for example, the inflationary universe of Guth<sup>38</sup>). Delaying the phase transition reduces the number of monopoles produced, as the horizon volume grows with time and only about one relic monopole is produced per horizon volume. As no suppression mechanism yet proposed seems compelling, the number of monopoles present today, if any, is hard to determine. Clearly some observational information would be useful.

Past searches for magnetic monopoles have usually looked for the ionization caused by the passage of a monopole through matter. Because the monopoles of GUTs are expected to be heavy and slow, the past experimental limits do not apply. At Santa Barbara, Cline outlined his proposal to search for supermassive magnetic monopoles at a huge steel plant in Mt Iron, Minnesota. Cline believes that the relic monopoles that have bombarded the Earth since its formation became bound to ferromagnetic domains. Heating iron ore above the Curie point destroys the domains, thus releasing the monopoles. The perfect place to do the experiment is at the Mt Iron processing plant run by United States Steel, where there is a pipe which carries 18 million tons per year of iron-ore above the Curie point, releasing their pent-up monopoles to be detected as they fall in the Earth's gravitational field. Results of such searches will be awaited by both particle physicists and cosmologists. The discovery of a magnetic monopole would be direct evidence for grand unification and the spontaneous symmetry breaking of the GUT.

On a much smaller scale, but just as fundamental to both particle physics and cosmology, is the continued claim of the observation of fractional charge by a low temperature experimental group at Stanford headed by Fairbank<sup>39</sup>. The importance of this experiment to particle physics is obvious, but cosmologists also have a stake in the results. Just as the monopoles were the fossil remains of the early Universe at temperatures of 10<sup>15</sup> GeV, fractional charge may be the remnant of the period in the early Universe when hadrons were formed out of the quark gas.

The most obvious interpretation of the Fairbank experiment is the existence of free, fractionally-charged quarks. However, it is generally believed (but not rigorously proved) that in the SU(3) colour gauge theory of quarks and gluons, coloured objects (for example, quarks) must always be bound into colourless states which have integral charge. For this reason the Stanford experiment has worried particle physics theorists. One possibility is that SU(3) is also spontaneously broken, but at a very small energy scale, ~10-50 MeV (refs 40, 41). This allows for the existence of free coloured objects, like quarks. Other possibilities exist: the Stanford group could be observing leptons (which are not coloured) with non-integral charge, or perhaps they are seeing bound states of quarks and other integrally charged coloured objects which would result in fractionallycharged, colourless objects. Unfortunately, as particle physics does not supply a unique model to explain the existence of fractionally-charged states, cosmologists cannot give a unique answer for the expected abundance from production in the early Universe. Wagoner reported that the relic abundances predicted from various models range from uncomfortably large to undetectably small<sup>42</sup>.

#### Phase transitions

During the 30 or so orders of magnitude of thermal history of the Universe  $(T \sim 10^{32} \text{ K} \rightarrow 3 \text{ K})$  many phase transitions associated with spontaneous symmetry breaking (SSB) should have taken place<sup>43</sup>, including the SSB of the GUT, of SU(2)×U(1), and perhaps the SSB of other intermediate symmetry stages. During these phase transitions it is likely that interesting phenomena occurred: during the GUT transition baryosynthesis and monopole production, and in all the stages of SSB, the possible production of entropy, creation of structure (that is, primordial density fluctuations), and generation of a cosmological term.

The standard mechanism (or crutch) for SSB is the Higgs mechanism. The details of the SSB transition depend on the parameters of the Higgs sector of the theory. If the transition is first order, there may be a large entropy release, which if it occurs after baryosynthesis dilutes the baryon asymmetry. (The baryon asymmetry is more correctly quantified as the baryon-to-entropy ratio rather than the baryon-to-photon ratio; however, today the two are essentially equivalent as most of the entropy in the Universe is in the 3 K background.) In the simplest model of SSB (Coleman-Weinberg symmetry breaking) it has been shown that the large entropy release associated with the SSB of  $SU(2) \times U(1)(T \sim 300 \text{ GeV})$  would dilute the baryon asymmetry produced during baryosynthesis by an unacceptably large factor, that is, leading to  $B \le 10^{-11}$  today<sup>44-46</sup>.

More intriguing are the possible cosmological effects associated with the vacuum energies which result from SSB. The vacuum energy associated with the Higgs condensate corresponds to a uniform energy density which acts like a cosmological term (A), and which charges by  $0(T_c^4)$  during a phase transition which occurs at temperature  $T_c$ . We know that the cosmological term today is not significant,  $(\Lambda/8\pi G) \le 4 \times 10^{-29} \text{ g cm}^{-3} \cong 10^{-46} \text{ GeV}^4$ . It seems that unless one specifies an initial compensatory, 'true' cosmological term to cancel the 'induced' ones, the Universe would be left with an enormous cosmological constant due to SSB. Guth has discussed the so-called inflationary universe, in which the cosmological term temporarily dominates the dynamics of the Universe<sup>38,47</sup>. An initial compensatory cosmological constant,  $\Lambda_i/8\pi G \sim 0(T_c^4)$ , is initiated to cancel the induced cosmological term associated with the GUT phase transition  $(T_c \sim 10^{15} \text{ GeV})$ . If the phase transition proceeds slowly, then the cosmological term  $\Lambda_i$  will soon begin to dominate the dynamics and will do so until it is cancelled when the transition has been completed. During this period the Universe undergoes a de Sitter phase in which the expansion is exponential<sup>47</sup>. The de Sitter phase has several potentially beneficial effects. First, the horizon (distance over which light signals can propagate) is inflated to encompass most of the observed Universe today, whereas in the usual FRW model, the horizon at the GUT epoch contains only 1 baryon. This could explain why on the largest scales the Universe is so smooth, as a patch of the Universe which could have been smoothed by particle interactions before the de Sitter phase is inflated to an enormous size during this epoch. The inflated horizon might also allow for the production of large-scale (galactic size and larger) density fluctuations which are necessary for galaxy formation. As mentioned earlier, the large horizon might possibly provide a solution to the monopole problem. When the transition has been completed, there is a large entropy release (baryosynthesis proceeds after this). This could explain the Universe has expanded so long without recollapsing or becoming negative—curvature dominated (in units of the fundamental time unit,  $t_{\rm Planck} \sim 10^{-43} \, {\rm s}$ ,  $\tau_{\rm Universe} \sim 10^{60} \, {\rm t_{Planck}}$ ). The curvature term grows in importance with time; as it is not significant today, earlier it must have been far less significant than the energy density term. Why this is the case is a mystery (the so-called 'flatness problem'). However, the tremendous entropy release would provide a natural explanation because it

allows the energy density to increase relative to the curvature term by a very large factor. Guth's 'inflationary scenario' is not without its complications. First, there is the problem of gracefully returning to FRW behaviour; and second, it presupposes the reality of these enormous induced cosmological terms associated with SSB. The cosmological term today is essentially zero; perhaps we should adopt the point of view that it has always been zero (for reasons we do not understand).

#### Fundamental problems

The 6-month program and week-long intensive workshop at Santa Barbara were both evidence that cosmology and particle physics is a young field that has come of age. As we have tried to stress here, the symbiotic relationship which exists between these two fields is one in which information flows in both directions: cosmology can constrain particle physics theories and particle physics can have profound implications for cosmology. Cosmological constraints restrict the class of viable theories, rather than provide guidance or direction. However, there is the hope that particle physics theories, GUTs in particular, might help to resolve some of the fundamental problems of classical (that is, non-quantum) cosmology. To conclude, we shall try to assess the impact to date and the possible future impact of GUTs on what we consider to be the six fundamental puzzles of classical cosmology<sup>48</sup>.

The most significant contribution of grand unification is baryosynthesis. Although we are still a long way from being able to predict the precise magnitude, or even the sign of the baryon asymmetry with GUTs, for the first time a framework exists for understanding why there is a baryon asymmetry when the laws of physics at the microscopic level are so nearly symmetrical.

The introduction of GUTs to cosmology, while appearing to have resolved one puzzle, unfortunately seems to have created another: the monopole problem. All the straightforward GUT scenarios of the early Universe predict that relic, superheavy monopoles ( $M \ge 10^{16}$  GeV) should today provide enough mass density to close the Universe many times over ( $\Omega \ge 10^{14}$ ). Perhaps, the solution is already at hand; however, it is equally likely that the resolution of the problem will be more subtle, and may even come at a very fundamental level with other important implications. The detection of relic monopoles and the determination of their cosmic abundance would be of the greatest significance for both particle physics and cosmology.

Another fundamental problem is the 'flatness' problem<sup>49</sup> which can also be regarded as an 'age' problem. There is only one fundamental time scale:  $t_{\rm Planck} \sim 10^{-43}\,\rm s$ ; the age of the Universe is  $\sim 10^{60}\,t_{\rm Planck}$ . In newtonian language, the 'flatness' problem is: the initial (at  $t_{\rm Planck}$ ) kinetic and potential energies of the Universe must have been equal (and opposite) to an accuracy of some 50 or so decimal places, otherwise the Universe would have long since recollapsed or entered a coasting phase (dynamics dominated by negative curvature). Guth's 'inflationary universe' may answer this problem, but at present there are other serious problems inherent to the scenario.

Next, there is the homogeneity problem: on the largest scales (≥10 Mpc) the Universe is very smooth, while on smaller scales it is quite lumpy (stars, galaxies, clusters, and so on). In the standard FRW cosmology, the large-scale homogeneity cannot be explained by causal processes, because causally distinct regions are uniform to a high degree of accuracy. Regions of the sky separated by more than ~1° or so were causally disconnected when the microwave photons we detect today were emitted, and yet have temperatures which are equal to within -1 part in 103. Given the 'proper spectrum' of initial small inhomogeneities (which is also a matter of disagreement), the present structure can be understood as being a result of the growth of the small fluctuations due to gravitational instability. The origin of the initial inhomogeneities is still a mystery which is also exacerbated by the existence of particle horizons in FRW models. The creation of fluctuations at very early times (for example, during a phase transition) is severely limited by the size of the horizon, and for this reason the resulting spectrum of

perturbations is usually far too small to be of any importance. Again, Guth's scenario may help to resolve both parts of the homogeneity problem, as the horizon problem is effectively circumvented.

GUTs thus far have shed no light on why the present cosmological term is so small. As is well known, quantum field theories (for example, quantum electrodynamics) predict an infinite energy density associated with the vacuum, which results in an infinite cosmological constant. (The Casimir effect strikingly demonstrates the reality of the vacuum energy density.) With a spontaneously broken gauge theory the situation is even more perplexing as the vacuum energy density changes during each stage of SSB. Even if one chooses to ignore the infinite contribution to the cosmological term, one must face the induced cosmological constants associated with each stage of SSB. If an initial compensatory, 'true' cosmological term is introduced to cancel the induced ones, then to cancel the cosmological constant which results from the SSB of the GUT, the initial cosmological constant must be specified to an accuracy of >100 decimal places. It is the assumption of the reality of these induced cosmological terms associated with SSB that leads to Guth's 'inflationary universe'. It is perhaps equally reasonable to suppose that as the cosmological term is essentially zero today, it has always been zero (for an unknown reason). It seems clear that a satisfactory solution to the cosmological constant problem will involve connections between cosmology and quantum field theory at a very deep level.

GUTs have also had very limited impact on the isotropy problem: why is the Universe isotropic to such a high degree of precision? The isotropy is evidenced by the 3 K background, galaxy counts, and the X-ray background.

The solution to some or even all of the five unresolved conundrums may well involve quantum gravity. As was discussed by Hartle, Hu and Parker at the Santa Barbara workshop, there are indications that particle creation due to quantum gravitational effects is highly efficient in damping initial anisotropy<sup>50</sup>, and that quantum gravitational effects may remove particle horizons<sup>51-54</sup> from cosmological models, perhaps leading to a solution to both parts of the horizon problem. However, given the magnitude and fundamental nature of the problem of formulating a quantum theory of gravity, it seems most prudent not to pin one's hopes on quantum gravity, but to pursue solutions that do not involve quantum gravity. It is not implausible that GUTs could provide solutions to most of these five puzzles.

We benefited greatly from conversations with members of the Early Universe Program and participants at the week-long workshop in Santa Barbara at the NSF's ITP. We especially thank the organizers of the Early Universe Program (G. Steigman and J. Hartle), of the Cosmology and Particle Physics Workshop (D. N. Schramm, G. Steigman and J. Hartle), and the director of the ITP, Walter Kohn. This work was supported by the NSF PHY 77-27084 at Santa Barbara and by the DOE at Los Alamos and Chicago (DE-AC02-80ER10773).

Observations of two stellar occultations by Neptune were used to search for possible equatorial and polar rings. No ring occultation events were identified, and an upper limit of 0.07 can be placed on the optical depth of any equatorial rings greater than 5 km wide with radii greater than 31,400 km. Any ring system of Neptune must be much less extensive than the ring systems of Uranus and Saturn, but a jovian-type ring of low optical depth would have escaped detection by our search. THE unexpected discovery<sup>1</sup> of rings around Uranus in 1977 excited new interest in planetary rings and the extreme narrowness of its nine rings—some only a few kilometres wide in the radial direction—created a new puzzle for dynamicists<sup>2,3</sup>. The interest increased in 1979, when a ring system was found around Jupiter<sup>4</sup>. The three known ring systems appeared strikingly different: Jupiter's, of extremely low optical depth; Saturn's, broad and bright; and the uranian rings, dark and narrow. Voyager 1 established an important similarity between the saturnian and uranian rings, when its high resolution images revealed that a multitude of narrow saturnian rings constitute the several broad rings that we see from Earth<sup>5</sup>.

### Rings around Neptune?

Reports of visual detection of rings around Neptune, made shortly after the planet's discovery in 1846, have been either withdrawn or unconfirmed<sup>6</sup>. Furthermore, the question of whether Neptune has rings cannot be answered on theoretical grounds, as the origins of the three known ring systems have not been established and may all be different<sup>7-12</sup>. One might suspect that because three of four giant planets have rings, Neptune should also—assuming a ring system results directly or indirectly from the formation of a giant planet. On the other hand, the three planets with rings also have regular satellite systems, but Neptune's satellite system is peculiar<sup>13</sup>. It has only two confirmed satellites: Triton, a large satellite with an inclined retrograde orbit, and Nereid, a distant satellite with a highly eccentric orbit.

#### **Techniques**

The most sensitive techniques for detecting planetary rings have been Voyager imagery and stellar occultations<sup>14</sup>. Since Voyager 2 is not due to explore the Neptune system until 1989, we have selected from lists of possible occultations by the Neptune the most appropriate events for detecting a ring system. Using occultations to search for rings around Neptune is more difficult than using these to observe the uranian rings, because an equatorial ring system around Neptune would subtend an angle of only 2 arcs perpendicular to the motion of Neptune; the uranian rings subtend an angle of 8 arcs perpendicular to the motion of uranus. Furthermore, a complete search for rings around Neptune must include the possibility of rings in the non-equatorial, yet stable, orbits described by Dobrovolskis<sup>15</sup>. The only previously reported occultation observations are those of Nicholson and Jones 16, who obtained incomplete data for an occultation on 21 August 1980. They describe a possible ring event (at a projected equatorial radius of 1.5  $R_N$ ), but there have been no corroborating data.

The two occulations used in our search were (1) star no. 28 in the list of Mink et al.<sup>17</sup> which occurred on 10 May 1981, and (2) an uncatalogued star that we identified as an observable event only a few days before it occurred on 24 May 1981. As shown in Table 1, the first event was observed from various sites around the Pacific Ocean, while the second was observed only from Cerro Tololo. Observations were made at several wavelengths

Table 1 Ring search observations								
Date	Observatory	Telescope† aperture (m)	Filter*	Observers				
10 May 1981	Mauna Kea	3.0 2.2 0.6	$R$ $B, R_1$ $R_2$	Elhot, Mink Liller, Pingree Franz, French				
10 May 1981 10 May 1981	Siding Spring Mount Stromlo	1.0 1.9	_	Dunham, Zarro Jones, Nicholson				
24 May 1981	Cerro Tololo	0 <b>8</b> <b>4.</b> 0	B, R <sub>1</sub>	Baron, Smith Elias, Martin				

<sup>\*</sup>The filters had the following centre wavelengths and passbands (FWHM): B, 0.44 and 0.10  $\mu$ m,  $R_1$ , 0.78 and 0.18  $\mu$ m;  $R_2$ , 0.87 and 0.06  $\mu$ m; K, 2.2 and 0.4  $\mu$ m.

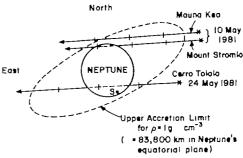

Fig. 1 Regions probed for rings around Neptune. The solid lines show the tracks of the occulted stars relative to Neptune as seen from Mauna Kea, Mount Stromlo and Cerro Tololo. The tracks begin at 11 00 UTC for the 10 May event and at 2:00 UTC for the 24 May event. The tic marks on each track occur at 30-min intervals. The dashed ellipse shows the upper accretion limit <sup>22</sup> in Neptune's equatorial plane. Inside this limit, the tidal force from Neptune exceeds the gravitational attraction for spherical particles of equal size. Here, such particles could not accrete into larger bodies, but would remain as rings (see note added in proof).

with equipment described elsewhere 18-20. In each case the observers recorded (on magnetic tape) the intensity of starlight as the star passed behind the region around Neptune that could accommodate rings.

#### Results

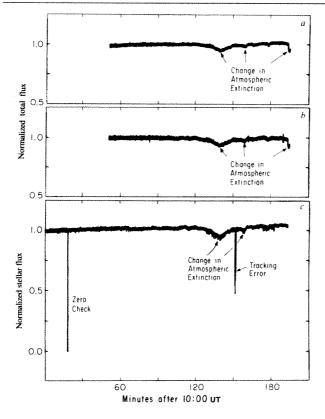

Figure 1 shows a plot of the tracks of the stars as they would appear in the sky, the dashed portions indicating where Neptune occulted the star. The duration of the Neptune occultations, along with the occultation radius of Neptune obtained from Taylor's circular solution<sup>21</sup>, were used to establish the positions of the tracks with respect to Neptune. Also shown is the upper accretion limit for material of  $\rho = 1~{\rm g~cm^{-3}}$  in the equatorial plane of Neptune. Within the upper accretion limit, the gravitational attraction of spherical bodies of equal size is less than the tidal force from Neptune<sup>22</sup>. Hence, spherical particles of equal size would remain as rings, and not condense into satellites, inside this limit. For particles of unequal size, the accretion limit would be closer to Neptune. The direction of Neptune's pole in Fig. 1 was assumed to coincide with the pole about which Triton's orbit precesses<sup>23,24</sup>. Our assumed direction could differ by a few degrees from the actual direction of Neptune's pole, which cannot be calculated because Triton's mass is uncertain. The sky-plane velocity of the star was 19 km s<sup>-1</sup> for the first event and 22 km s<sup>-1</sup> for the second.

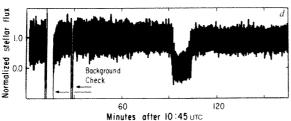

The two events combined cover the space for rings around Neptune. Fortunately for this search, Neptune did not occult the star as seen from Mauna Kea, so that this track covers the

Table 2 Regions probed for rings

UTC on 10 May 1981		ected equa istance (kr Siding Spring	UTC on 24 May 1981

13.30	173,800	154,100	153,400			

Projected equatorial distances for times other than those tabulated should be obtained from three-point interpolation of the tabulated values. Figure 1 can be used to determine when the star was behind the planet and we could not probe for rings; Fig. 2 shows the time intervals when data were being acquired. Minimum equatorial distances are. MKO, 61,700 km at 11:48 UTC; SSO, 48,400 km at 11:58 UTC; MSO, 47,600 km at 11:58 UTC, and CTIO, 31,400 km at 3:08 UTC.

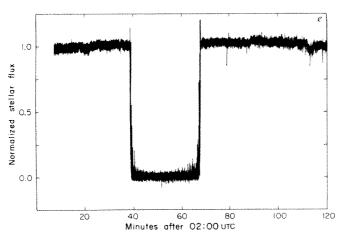

Fig. 2 Intensity versus time for: a-c, the 10 May event from Mauna Kea; d, the 10 May event from Mount Stromlo; e, the 24 May event from Cerro Torolo. All data have been averaged at 0.2s. Frames a, b show the combined light from Neptune and the star observed simultaneously at 0.44 µm and 0.78 µm with the 2.24-m telescope. Frame c shows the intensity at 2.2 µm observed with the IRTF. All notable dips in signal can be ascribed to causes other than ring occulations. In d the times of immersion and e immersion of the star behind Neptune were used to calculate the apparent position of the star relative to neptune. In e the large increases in signal at immersion and emersion by Neptune are the occultation spikes, caused by density variations in the atmosphere by Neptune. The dip in signal at 3:18:41 UTC is too narrow to have been caused by a ring occultation. The remaining conspicuous dips could not have been caused by continuous equatorial rings, or corresponding dips would have been observed during the 10 May occultation.

possibility of polar rings. For equatorial rings, Table 2 gives the projected distance from the centre of Neptune in its equatorial plane, as a function of time, for all four stations. The minimum distance probed was from Cerro Tololo, just as the star emerged from behind the planet (at a point corresponding to 31,400 km [1.3  $R_N$ ] in the equatorial plane).

The observed intensities versus time are shown in Fig. 2 for Mauna Kea, Mount Stromlo and Cerro Tololo. The averaging time was chosen to match the width of a diffraction-limited occultation profile, which would have been produced by a ring narrower than  $\sim 4.6$  km (refs 25, 26). Note that the star occulted on 10 May had a projected diameter at Neptune of  $\sim 10$  km (inferred from *JHK* photometry), which would broaden any ring occultation profiles to about twice their diffraction limit.

First we examine the data obtained with the 2.24-m telescope and IRTF (NASA's 3.0-m IR telescope facility), displayed in Fig. 2 a-c. As the spectra of Neptune and the star are not similar, the relative contributions of each are quite different at the three wavelengths observed. For the blue channel, the contribution of the star is <1% of the total signal; for the red channel, the star contributes 21% and for the 2.2-µm channel the stellar contribution is >99%. Hence, a partial occultation of the star by material near Neptune would not be detectable in the blue channel, and would have different fractional drops in the red and 2.2-µm channels. On the other hand, a change in atmospheric extinction (assuming it was not wavelength dependent) would cause approximately the same fractional drop in total flux for all three channels. A third possible cause of a drop in signal, a guiding or tracking error by one of the telescopes, would appear in the data from one telescope.

All observed drops in signal have explanations other than occultations by possible rings. These have been marked in Fig. 2. The small dip in the red channel near 11:20 UTC occurred during a focusing adjustment of the telescope. The remaining dips in the IRTF signal are <5% of the stellar intensity. Hence, we conclude that any rings of Neptune within the region probed from Mauna Kea, (>5 km wide in the sky plane plane projection) must have an optical depth <0.05.

The data from the 0.8-m telescope at Mount Stromlo, shown in Fig. 2d, contain the occultation that we used to calculate the path of the star with respect to Neptune. Although the data are noisier than those obtained from Mauna Kea, the star as seen from Mount Stromlo probed closer to Neptune, and these data would have revealed any rings similar to the  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  and  $\varepsilon$  rings of Uranus<sup>14</sup>. The 2.2-µm data from the 1.9-m telescope at Mount Stromlo (not displayed) have much better signal-to-noise ratios than those obtained with the 0.8-m telescope, and nine dips in signal occurred in these data that were candidates for ring occultations. However, all these events happened at times when corresponding events would have been visible from Mauna Kea as well, if they were caused by rings. The lack of corresponding events at Mauna Kea leads us to conclude that the events recorded with 1.9-m telescope were caused by thin clouds and/or poor seeing. If any had been due to a total occultation by a small satellite, a corresponding event would have been recorded with the 0.8-m telescope. No total occultations, except for Neptune, were recorded (see Fig. 2d).

The data from the occultation by Neptune on 24 May 1981 are shown in Fig. 2e. The increases in signal above full-scale at planetary immersion and emersion are the spikes caused by density variations in Neptune's atmosphere. As this event was observed with only one telescope, and at a single wavelength, we had more difficulty in establishing the cause of dips in signal. The most conspicuous dip occurred at 03:18:41 UTC, which corresponds to an equatorial radius of 1.55  $R_{\rm N}$ . Curiously, this is near the same equatorial radius of the possible ring occultation reported by Nicholson and Jones<sup>16</sup>. However, we believe both events had causes other than rings and their coincidence is fortuitous. At high resolution the CTIO event has a FWHM of only 2.7 km. This is about half the minimum width (4.6 km, due to diffraction<sup>25,26</sup>) that could have been produced by a ring or small body at the distance of Neptune. Hence we conclude that

this dip was not caused by a ring or small body near Neptune. The other three notable dips in signal that occur after 3:25 UTC were apparently not caused by continuous equatorial rings either, as this region was probed during the 10 May event, with negative results. In fact, the dip at 3:25 UTC occurred when the planet was near the edge of the photometer beam. Other than the dips just discussed and the occultation by Neptune, the signal never drops below 0.93 of its unocculted value. Hence, we place a limit of 0.07 on the optical depth of any equatorial rings of Neptune, with widths > 5 km and radii > 31,400 km.

Our upper limit is about four times lower than would have been necessary to detect the least opaque uranian ring (ring 6), but we could not have detected a jovian-type ring, of low optical depth. (The jovian ring has not yet been detected by radio or optical occultation<sup>27,28</sup>.) Hence, in terms of detectability by occultations, any system of rings around Neptune must be much less extensive than the uranian system.

In terms of the amount of material that could exist as neptunian rings, our limit on the optical depth allows a large range of masses. On one hand, we could have detected as little as 10<sup>12</sup> g of material concentrated into a narrow ring. However, the form of the material least amenable to detection by our observations would be a collection of small satellites. ~1 km in diameter. This diameter would be too small for an individual satellite to cause an observable occultation. If the mean optical depth of the collecton of satellites were < 0.07, we would not have detected the ensemble either. If the material were carbonaceous ( $\rho = 3 \text{ g cm}^{-3}$ ), the combined mass of these satellites could be as great as  $4 \times 10^{23} \text{ g}$ . This is comparable to recent upper limits on the mass of Saturn's rings<sup>29</sup> and would equal that of a single satellite, 600 km in diameter.

#### Conclusions

It is puzzling to reconcile our failure to detect rings with the recent discovery (through occultation observations) of an apparently small, third satellite of Neptune30, with an orbital radius of  $3 R_N$ . As the odds against discovering a lone body in this manner would be so great, one might conclude that Neptune has several, if not many, small satellites. One small satellite orbits just inside, and another just outside, the F ring of Saturn; at least two exist near Jupiter's ring and several small satellites have been postulated to be intimately associated with the uranian rings.

Hence we must still entertain the possibility of a neptunian ring system that we were unable to detect. A further opportunity to search for rings with occultations, with better sensitivity, occurs<sup>17</sup> in 1983, and Voyager encounters Neptune in 1989. If these opportunities fail to reveal rings, then we need wait only ~ 108 yr until tidal interaction between Neptune and Triton will have caused Triton to move close enough to Neptune to break up into what should be a spectacular system of rings<sup>3</sup>

We thank the telescope allocation committees of Mauna Kea, the IRTF, Mount Stromlo and Siding Spring for our observing time and B. Schaefer, F. Cheigh, G. Martin, R. Smith and D. Zarro for observational assistance. This work was partially supported by grants from NSF (AST-7827879 and AST-8010699) and NASA (NSG-7526 and NSG-7603).

Note added in proof: An error of  $2\frac{1}{3}$  was found by P.D.N. in Smoluchowski's expression for the upper accretion limit<sup>22</sup>. For  $\rho = 1 \text{ gm cm}^{-3}$ , the correct radius of the upper accretion limit in Fig. 1 is 66,500 km (not 83,800 km).

# Global satellite measurements of water vapour, wind speed and wave height

# Dudley B. Chelton, Kevin J. Hussey & Michael E. Parke

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA

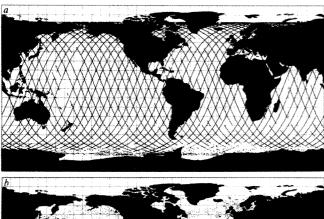

Data from the 100 days of Seasat observations in 1978 provided the first global maps of mean wind speed and wave height measured from satellites. They reveal previously unknown features in both fields and demonstrate the potential for satellite monitoring and forecasting of the worldwide sea state.

ON 28 June 1978 the United States launched Seasat, an experimental satellite to demonstrate the utility of microwave remote sensing of the ocean surface. On board were three active microwave radars (an altimeter, a scatterometer and a synthetic aperature radar) and two passive radiometers (a scanning multichannel microwave radiometer and a visible and IR radiometer). Because of their relative insensitivity to cloud cover comparedqith visual and IR sensors, microwave sensors have the advantage of all weather operations. A more detailed description of the Seasat mission is given in ref. 1. Although a short circuit in its electrical system ended the observations

prematurely on 10 October 1978, Seasat provided the first global pictures from space of wave height and wind speed. Seasat also measured atmospheric liquid water, water vapour, sea-surface txperature and sea-surface topography with better accuracy than from previous satellites.

#### Measurements

Results of global measurements of atmospheric water vapour by the Seasat Scanning Multichannel Microwave Radiometer (SMMR) and wave height and wind speed by the Seasat altimeter (ALT) are presented here. The primary objective of ALT

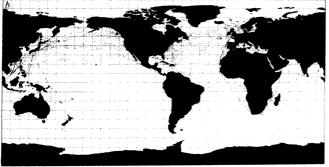

Fig. 1 Representative 3-day global data coverage by: a, the Seasat altimeter; and b, conventional ship weather reports (courtesy of D. McLain, National Marine Fisheries Service, Monterey, California). Both the examples shown are for 9-11 August 1978.

was to measure the height of the sea surface relative to a reference ellipsoid. However, the shape and power of the returned radar pulse are also used to infer wave height and wind speed at the sea surface. The 13.5-GHz Seasat altimeter is a successor of the GEOS 3 altimeter with a shorter pulse width (3.125 ns) and higher repetition rate (1,020 Hz) which lead to more precise measurements of sea surface height (better than 10 cm). The 1.59° half power beam width directed at the spacecraft nadir gives a cross track sea-surface footprint that increases from 2.4 km for 0 m wave height to 11.6 km for 20 m wave height. For the 1-s averages presented here, the along track sea-surface footprint ranges from 9.4 to 18.7 km. For typical wave heights of 3 m the ALT footprint is  $\sim 5 \times 12$  km.

ALT operated intermittently, producing data over a total of 78 days. Because Seasat circled the Earth about 14 times each day at an altitude of ~800 km and an inclination of 108°, successive equatorial crossings moved in a westward direction with a separation of ~2,500 km. In 3 days, the equatorial spacing of the ground tracks was about 900 km. The full Seasat mission resulted in global coverage with ~135 km equatorial spacing of ground tracks. Typical 3-day ALT data are shown in Fig. 1a. The gaps in the data are due either to ALT being temporarily turned off or to a flagged error condition (such as anomalously high wave height or wind speed estimates or a satellite tilt angle beyond 0.5°). For comparison, global data from conventional ship weather reports are shown in Fig. 1b for the same 3-day period: ALT provides more than an order of magnitude increase in the quantity of data (131,700 compared with 7,600 observations). Even more importantly, the spatial coverage by ALT is more nearly uniform over the globe than the ship reports which tend to be concentrated along standard shipping routes in the Northern Hemisphere.

A detailed description of how the wave height can be extracted from the ALT radar return pulse is given in refs 2, 3. The waves stretch the leading edge of the returned radar pulse because of early returns from wave crests and later returns from wave troughs. Thus, the slope of the leading edge of the returned radar pulse is inversely related to the wave height. The shape of the returned pulse has been empirically related to the significant wave height (SWH) defined to be four times the r.m.s. of the crest-to-trough wave height, roughly equivalent to the average

height of the one-third largest waves present in the ALT footprint. Computations of wave heights were carried out on board the satellite providing real-time wave measurements. Two simple bias corrections were later applied on the ground: a pre-launch calibration bias removal and a bias correction due to satellite tilt angle (flagged if  $>0.5^{\circ}$ ). A scatter plot comparing 51 buoy measurements with the ground-processed ALT estimates of SWH is shown in Fig. 2a (see ref. 3). The mean and r.m.s. differences (ALT minus buoy) over this sample data set are small (28 and 38 cm respectively). Apparently, the on-board processor estimates of SWH > 2 m may be biased  $\sim$ 50 cm high but the present sample size is too small to confirm this.

The altimeter antenna measures specular return from the nadir sea surface which is primarily determined by that part of the ocean wave spectrum with wavelengths longer than the -2-cm wavelength of the incident radiation. As the wind speed increases, the sea-surface roughness increases and a greater fraction of the incident radiation is scattered away from the satellite. Thus the power of the returned radar pulse is inversely related to the wind speed. A more detailed description of the relationship between radar backscatter and the wind speed is given in ref. 4. A scatter plot comparing 87 buoy measurements with ALT estimates of wind speed is shown in Fig. 2b (see ref. 3). A direct comparison of Seasat and GEOS 3 altimeter measurements during the overlap of the two satellite missions indicated that the Seasat backscatter values were biased 1.6 dB higher than GEOS 3 (see ref. 3). The present wind estimates were generated from the Seasat ALT backscatter values by first removing this 1.6-dB bias and then using a wind speed algorithm previously derived for the GEOS 3 altimeter (see ref. 3). The mean and r.m.s. differences (ALT minus buoy) from this limited sample size are 0.25 m s<sup>-1</sup> and 1.58 m s<sup>-1</sup> respectively. The lack of data means that the reliability of the relationship at wind speeds in excess of 10 m s<sup>-1</sup> is questionable. However, experience with GEOS 3 indicates that an altimeter can provide reliable wind speed estimates to at least 20 m s<sup>-1</sup>. Investigations are underway to determine the accuracy of the Seasat ALT wind speed estimates over a broader range of conditions and from a larger data base.

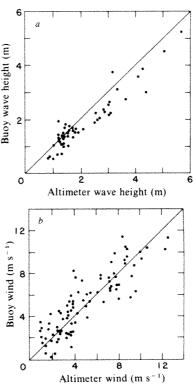

Fig. 2 a, Comparison of significant wave height estimated by the Seasat altimeter against 51 buoy measurements. b, Comparison of wind speed estimated by the Seasat altimeter against 87 buoy measurements. Data from ref. 3.

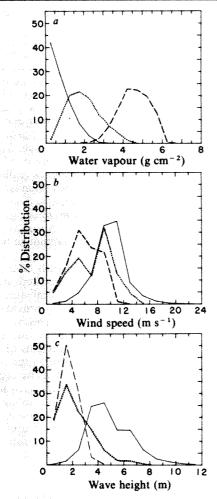

Fig. 3 Distributions of a, water vapour; b, wind speed; and c, wave height estimates from Seasat for the 5° lat. bands centred at 52.5° N (dotted curves), 2.5° N (dashed curves) and 52.5° S (solid curves). All observations between 7 July 1978 and 10 October 1978 are included.

An additional measurement required in any precision altimetric mission is the integrated atmospheric water vapour between the sea surface and the satellite. Water vapour estimates are necessary to make pathlength and attenuation corrections to the ALT radar pulse. On Seasat, integrated water vapour was estimated using the near nadir cell of the SMMR. The presence of water vapour between the satellite and the sea surface increases the atmospheric index of refraction which increases the effective radio frequency path length by 10-50 cm. The altimeter pathlength correction was estimated directly by a linear function of the SMMR brightness temperatures at 18, 21 and 37 GHz (both horizontal and vertical polarization). These pathlength correction estimates were then converted to total integrated atmospheric water vapour based on comparison with direct water vapour measurements from radiosondes. A detailed discussion of this procedure is given in ref. 5.

#### Cover picture

The 3.5-month Seasat climatological averages of integrated atmospheric water vapour, wind speed and wave height are shown on the cover. More than 3.5 million observations have been averaged globally into 2.5° square areas. The typical number of observations per 2.5° square is around 500 (higher at high latitudes where the satellite ground tracks converge). During the last month of the mission, Seasat was held in a locked orbit with 900-km equatorial spacing of ground tracks over an ~3-day repetition period. This resulted in an uneven sampling distribution over the 2.5° global grid in the 3.5-month averages presented here; 2.5° squares along the locked orbit ground track typically contained nearly twice as many sample data points over

the 3.5-month period as the 2.5° squares between locked orbit ground tracks. (The regions between locked orbit ground tracks were not sampled at all from 9 September to 10 October.) Consequently, to obtain useful pictures of water vapour, wind speed and wave height, the data had to be smoothed zonally with a 7.5° running mean filter (no smoothing meridionally), so the images on the cover effectively represent 3.5-month climatological averages over 2.5° lat. by 7.5° long. areas.

The average water vapour is shown in the upper panel. The highest values are in the tropics (especially the Asian monsoon region and the intertropical convergence zone in the eastern tropical Pacific) and the lowest are at high latitudes. The effects of cool dry air blowing equatorwards over the eastern ocean basins and turning westwards as the trade winds are also evident as well as the region of high water vapour in the southern intertropical convergence zone at about lat. 10° S in the western tropical Pacific. The anomalous observations close to Antarctica are believed to be due to the presence of ice producing increased microwave brightness temperatures.

The average wind speed measured by ALT is shown in the middle panel. Several classical features of the wind field are clear: the north-east and south-east trade winds separated by the doldrums (region of light winds) in both the Atlantic and Pacific Oceans; the horse latitudes (another region of light winds) separating the trade winds from the stormy westerlies in both hemispheres; the south-east trade winds in the south equatorial Indian Ocean and the high wind speeds from the summer monsoon in the northwestern Indian Ocean. The highest wind speeds are in the Southern Hemisphere winter storm region between 50°S and Antarctica (especially southwest of Australia). The narrow region of high wind speeds in the eastern tropical Pacific at about lat. 2° N between long. 90° W and 140° W is a feature previously not seen in ship wind reports which are very sparse in this region. Note also the jet of high wind speed off the coast of California (see ref. 6).

The lower panel shows the average significant wave height during the Seasat mission. This is the first accurate picture of global wave conditions and, we believe, the first reliable measurement by any method of ocean waves for winter season in the Southern Hemisphere. It reveals some interesting features. The average wave height is small in the summer Northern Hemisphere (generally 2-3 m) and the largest waves are located in the winter Southern Ocean where the wind speeds are highest (especially south-west of Australia where mean wave height is >5.5 m). The smallest waves are found in the western Atlantic and Pacific Oceans (average height <1.5 m) in regions of light winds. We expect that further analysis of the ALT wave height data will ultimately lead to a better understanding of the process of wind wave generation.

#### Discussion

The fact that the 2.1-m contour between 50° and 55° N in the North Pacific does not extend all the way to the coast can probably be explained by the coarse 2.5° lat. by 2.5° long, resolution of the data presented here. Examination of finer-resolution data in this region reveals that the apparent decrease in wave height in the 2.5° averages close to the coast is due to the presence of a distinct wave shadow behind Queen Charlotte Island (the largest of the many islands off the west coast of Canada). In the finer-resolution data, the 2.1-m waves extend all the way to the western shores of these islands but wave heights are <1 m behind the islands.

Note that ice in the ALT footprint causes very erratic behaviour in the shape and power of the returned radar pulse which typically results in rapid changes from very high to very low wave height estimates by ALT. This anomalous behaviour is flagged on the ALT geophysical data records gferated fromhhe sensor data by the Jet Propulsion Laboratory, thus providing a potential method for mapping ice coverage from altimeter measurements. Anomalously high wave height estimates have been excluded from our data so that wave height estimates over ice are small. Thus the ice-covered area is represented in the

wave height map on the cover by the light-coloured region close to Antarctica.

While climatological averages emphasize geographical differences within each field, they give no indication of the range of conditions likely to be encountered in a particular region at different times. The rather striking zonal banding of each of the fields suggests that latitudinal distributions can provide some initial insight into water vapour, wind speed and wave height variability during the Seasat mission. The probability distributions of each of the three fields for the three 5° lat. bands centred at 52.5° N, 2.5° N and 52.5° S are shown in Fig. 3.

The features evident in the water vapour distributions in Fig. 3a are not surprising. They clearly show the higher integrated water vapour levels found in the tropics. Only 2% of the observations in the equatorial band were <3 g cm $^{-2}$  while 96%of the observations in the high southern latitude band were <2 g cm<sup>-2</sup>. This reflects the lower water vapour saturation level of the cold Southern Hemisphere winter air. The cool high northern latitude band shows intermediate water vapour values with 75% of the observations between 1 and 3 g cm<sup>-2</sup>. A more detailed study of the water vapour estimates might be useful in climatological studies of the global time variability of the latent heat of vapourization transferred from the ocean to the atmosphere.

The wind speed distributions in Fig. 3b show some unexpected features. As the high southern latitude band is in the winter storm region, the higher wind speeds in this band are not surprising. Large variations might also be expected due to the passage of individual storms. However, the winds in this band seem to be relatively steady: 68% of the observations were between 8 and 12 m s<sup>-1</sup>. In comparison, the trade winds of the equatorial band, which are noted for their steadiness, show a peak at much lower wind speeds but a broader distribution: 76% of the observations were between 4 and  $10\,\mathrm{m\,s^{-1}}$ . Another curious feature is the probability distribution for the high northern latitude band: the range of wind speeds is broader than either of the other two bands but there are two pronounced peaks, a primary peak at 9 m s<sup>-1</sup> and a secondary peak at 5 m s<sup>-1</sup>. Present studies are aimed at determining whether the double peaks arise from zonal averaging of an inhomogeneous

field or whether they reflect a seasonal change in the wind speed distribution during the 3.5-month period.

The wave height distributions are shown in Fig. 3c. The equatorial band has the narrowest range of wave conditions: 70% of the waves were <2 m and virtually none were >4 m. In comparison, only 50% of the waves in the high northern latitude band were <2 m and 5% were >5 m. In contrast to both the equatorial and high northern latitude bands, the peak in the wave height distribution in the stormy high southern latitude band is at a much higher value (3.5 m as opposed to 1.5 m) and the range of wave conditions is much wider. Only 2% of the waves observed were <2 m and over 40% were >5 m. The secondary peak at 6.5 m is rather puzzling; it is difficult to explain in terms of wind forcing as there is no similar doublepeaked structure in the wind speed distribution in this latitudinal band. The double peaks probably result from zonal averaging of the large wave heights south and west of Australia with the smaller wave heights elsewhere in this 5° latitudinal band (see cover).

There is no way of knowing at present whether the 3.5-month average wind speed and wave heights presented here are typical for this time of year. However, these geophysical maps demonstrate the unique ability of satellites to provide global measurements of wind and wave conditions. This will be especially useful in data-sparse regions such as the Southern Hemisphere (see Fig. 1b) where present forecasts of weather and sea states are extremely unreliable. Even in the Northern Hemisphere, forecasting skill is limited in many regions by sparse data coverage over the oceans. An operational altimetric mission could improve worldwide sea state forecasting.

This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract with NASA. L. Fedor and G. Brown made their results (Fig. 2) available before publication of their own work.

# Dipoles of the $\alpha$ -helix and $\beta$ -sheet: their role in protein folding

Wim G. J. Hol\*, Louis M. Halie\* & Christian Sander<sup>†</sup>

\* Laboratory of Chemical Physics, Department of Chemistry, University of Groningen, Nijenborgh 16, 9747 AG Groningen, The Netherlands † Biophysics Department, Max Planck Institute of Medical Research, Jahnstrasse 29, Heidelberg, FRG

As a result of the regular arrangement of peptide dipoles in secondary structure segments and the low effective dielectric constant in hydrophobic cores, the electrostatic energy of a protein is very sensitive to the relative orientation of the segments. We provide here evidence that the alignment of secondary structure dipoles is significant in determining the threedimensional structure of globular proteins.

IT has long been known that in the  $\alpha$ -helix the alignment of the peptide dipoles parallel to the helix axis gives rise to a macrodipole of considerable strength (for review see ref. 1). With a dipole moment for each peptide unit of ~3.5 D, a helix of, for example, 10 residues has a dipole moment of 34 D, as 97% of the peptide dipole points in the direction of the helix axis. It has been shown<sup>2</sup> for points near the helix termini that the effect of the helix dipole is equivalent to the effect of half a positive unit charge at the N-terminus of the helix and half a negative charge at the C-terminus. The same authors provided evidence that the considerable electric field due to the helix dipole moment is used by proteins in: (1) binding negativelycharged groups, such as phosphate groups; (2) rendering protein side chains located near the N-terminus more nucleophilic; and, (3) stabilizing charged transition states or intermediates along the catalytic pathway. So far ~20 helices have been observed which bind negatively-charged groups near their N-termini. Another 10 proteins have their active site close to the Nterminus of a helix (W.G.J.H., unpublished results). For papain, an extensive quantum mechanical calculation3 showed that the field generated by the helix dipole is a major factor in the stabilization of the sulphhydryl-imidazole ion pair essential in the catalytic mechanism of this enzyme<sup>4</sup>. Secondary structure formation also seems to be influenced by side chain-main chain electrostatic interactions<sup>5,6</sup>.

Here we extend the role of the helix dipole to the area of protein folding. In this we are motivated by the idea that the directionally sensitive and relatively long-range dipole-dipole interaction is an important factor in ordering the secondary structure in the hydrophobic interior of folded globular proteins.

#### Model calculations of helix-helix interaction

Figure 1 shows, for a simple case, the result of model calculations of the electrostatic energy between the backbone dipoles of two helices as a function of their distance and relative orientation. The strongest variation in energy occurs when one helix axis is turned by  $180^{\circ}$  relative to the other (Fig. 1b). The energy difference between a parallel helix pair and an antiparallel pair is considerable (Fig. 1b,c). These calculations

also show that the interaction between two helix dipoles reaches an upper limit at a helix length of  $\sim 35$  residues (Fig. 1d). We consider first the extent to which proteins containing helices and no  $\beta$ -sheets reflect these simple electrostatic model considerations. Proteins containing  $\beta$ -structures will be discussed later.

#### All-helical proteins

In an elegant analysis of protein structures, Levitt and Chotia<sup>7</sup> showed schematically three major types of all-helical structures. By assigning 'plus' signs to the N-termini and 'minus' signs to the C-termini (indicating the effective charge) in their two-dimensional drawings, the alternating pattern of plus and minus signs tentatively confirms the trend of our model calculations.

Estimates of the actual three-dimensional interaction energies between the helices in the all-helical and predominantly helical proteins tobacco mosaic virus (TMV)<sup>8,9</sup>, myoglobin<sup>10</sup> and parvalbumin<sup>11</sup> are given in Table 1. These calculations show

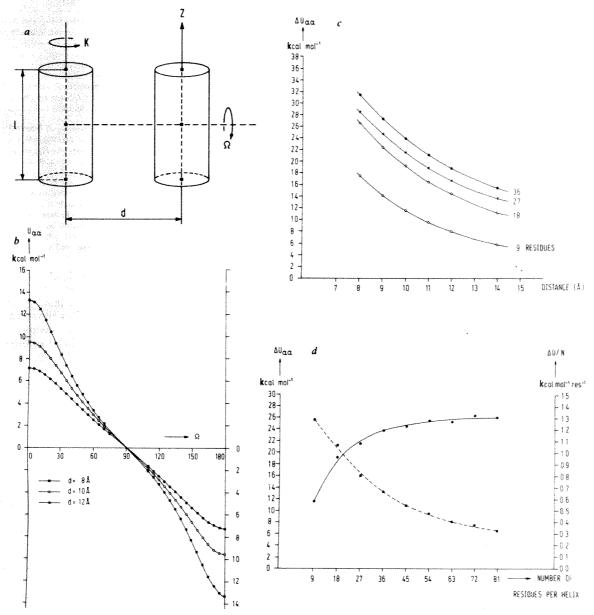

Fig. 1 a, The relative position and orientation of two helices in the simple case where the helix axes are perpendicular to the line connecting the centres. A helix can be rotated about its own axis by an angle K (with negligible variation in electrostatic energy) and about the inter-helical axis by an angle  $\Omega$  (with considerable variation in electrostatic energy) between two model  $\alpha$ -helices as a function of twist angle  $\Omega$ . The length of both helices is five turns, that is, 18 residues or 27 Å. c, The difference in electrostatic energy between a pair of parallel ( $\Omega = 0$ ) and a pair of antiparallel ( $\Omega = 180$ ) helices falls off gradually with increasing distance, d. d, The difference in electrostatic energy between a pair of parallel ( $\Omega = 0$ ) and a pair of antiparallel ( $\Omega = 180$ ) helices at a mutual distance of 10 Å as a function of helix (solid line). The figure illustrates that the difference becomes less important on a per residue basis for longer helices (broken line). For the model calculations, we used polyalanine in a helical geometry, generated by the program of Hermans et al. The only partial charges are those of the peptide group<sup>2</sup>: C, 0.42; O, -0.42; N, -0.20 and H, 0.20 unit charge. No cutoff radius was used and dielectric screening was neglected.

**Table 1** Calculated electrostatic interaction energies between the backbones of  $\alpha$ -helices and  $\beta$ -strands in various proteins

Protein	Type of protein	No. of $\alpha$ -helices	No. of β-strands	$U_{\alpha\alpha}$ (kcal mol <sup>-1</sup> )	$U_{lphaeta}$ (kcal mol $^{-1}$ )	Ref.
Met-myoglobin	$\alpha_{\mathbf{a}}$	9	***	-22.7	_	10
TMV	$\alpha_{\mathbf{a}}$	4		-14.3	-	8, 9
Parvalbumin	$\alpha_{\rm a}$	6	-	-11.8	. <del>.</del>	11
Cytochrome b <sub>5</sub>	$\alpha_*$	6	<b>-</b> ,	-4.7	****	22
Phospholipase A2	$\alpha_{\mathbf{a}} \beta_{\mathbf{a}}$	4	2	-8.3	-0.8	41
Cytochrome c	$\alpha_{\mathbf{a}}\boldsymbol{\beta}_{\mathbf{a}}$	4	3	-3.4	-1.4	42
Hen egg-white lysozyme	$\alpha_{\mathbf{a}}\boldsymbol{\beta}_{\mathbf{a}}$	6	5	-12.8	-1.6	19
Phage T4 lysozyme	$\alpha_{\mathbf{a}} \boldsymbol{\beta}_{\mathbf{a}}$	10	3	-23.5	-0.7	20
Thermolysin	$\alpha_{a}\beta$	7	14	-3.6	-5.4	21
Lactate dehydrogenase	$\alpha_{p}\beta_{p}$	9	15	+14.0	-14.0	43
Alcohol dehydrogenase	$\alpha_p \beta_p$	10	20	+14.2	-15.3	44
Glyceraldehyde phosphate dehydrogenase	$\alpha_{\mathcal{B}}\beta_{\mathfrak{p}}$	7	18	+5.8	-5.7	45
Adenylate kinase	$\alpha_{\beta}\beta_{p}$	10	5	• +4.9	-10.5	46
Rhodanese	$\alpha_{\mathfrak{p}} \beta_{\mathfrak{p}}$	10	10	+13.5	-10.3	32
Subtilisin	$\alpha_{p}^{p}\beta_{p}$	8	9	+5.2	-15.0	47
Dihydrofolate reductase	$\alpha_{p}\beta_{p}$	4	8	+3.2	-3.8	48
Flavodoxin	$\alpha_{p}\beta_{p}$	5	7	+13.3	-4.9	36
Triose phosphate isomerase	$\alpha_p \beta_p$	8	8	+6.6	-7.0	49
Carboxypeptidase	$\alpha_{p}\beta_{p}$	9	12	+11.4	-11.0	50
Papain/actinidin	$\alpha\beta + \beta_a$	6	8	+13.3	-6.6	51, 52

The table demonstrates the favourable alignment of  $\alpha$ -helices in all- $\alpha$  proteins and the compensation for unfavourable helix interactions by favourable helix-strand interactions in other proteins.  $U_{\alpha\alpha}$  is the sum of all main-chain dipole helix-helix interactions,  $U_{\alpha\beta}$  the sum of all main-chain dipole helix-strand interactions.  $U=\Sigma$  ( $qq_0/r_0$ ), where  $r_{ij}$  is the distance between two charges  $q_i$  and  $q_i$ , with no cut-off in r and with the partial charges? C=0.04.2, C=0.04.2, N=-0.20, C=0.04.2, N=-0.20, corresponding to a peptide dipole moment of 3.5 D in the direction of the N-H and O-C bonds. Indices i and j label the residues in the segments; i and j are not in the same segment. A dielectric constant was not used because of the breakdown on the atomic scale of continuum theories on which the concept of dielectric constant is based. This breakdown is illustrated quantitatively by molecular dynamics simulations<sup>53</sup>. The dielectric response, however, can be estimated and is physically due to the electronic polarizability of the protein atoms and the orientational polarizability of solvent water. The effects of the former can be separated into two contributions which occur in opposite directions. (1) Recent theoretical estimates of an effective dielectric constant for the non-polar atoms in the protein interior are  $\epsilon = 2$  (for example, derived from atomic polarizabilities<sup>54</sup>). This decreases U by a factor of  $\sim 2$ . (2) Cooperatively aligned backbone dipoles in both  $\alpha$ -helix and  $\beta$ -sheet mutually polarize each other, increasing the O+C and N+H dipoles by a factor of  $\sim 2$ . (2) Cooperatively aligned backbone dipoles in both  $\alpha$ -helix and  $\beta$ -sheet mutually polarize each other, increasing the other actions in the interior of a sphere of low dielectric surrounded by water: the screening is only effective near the surface and dies off quickly in the interior. As helices are usually nearer the protein surface than parallel  $\beta$ -sheets, this means that our  $U_{\alpha\alpha}$  values are an o

very favourable overall electrostatic interactions between the helices, in complete qualitative agreement with our model calculations. Although these energies are difficult to calculate precisely (see Table 1 legend), we do not expect any change in the qualitative conclusions when more accurate calculations are available.

The all-helical proteins myohaemerythrin<sup>12</sup>, ferritin13 cytochrome  $b_{562}$  (ref. 14) and cytochrome c' (ref. 15) strongly resemble the optimally antiparallel TMV structure16. The allhelical protein uteroglobin contains only antiparallel helices<sup>17</sup> The larger protein cytochrome c peroxidase 18 contains eight helices of which five form an antiparallel arrangement and none are aligned in parallel. Our model is also supported by the structure of 6-phosphogluconate dehydrogenase (M. Adams and S. White, in preparation): four pairs of antiparallel helices are wrapped perpendicularly around two long antiparallel helices which form the core of this protein. In addition, helices in the helical domains of hen egg-white lysozyme19, phage T4 lysozyme<sup>20</sup>, thermolysin<sup>21</sup> and cytochrome  $b_5$  (ref. 22) have a definite tendency to run antiparallel. This is reflected in the negative interaction energies  $U_{\alpha\alpha}$  calculated for these proteins (see Table 1).

#### Proteins with alternating $\alpha$ and $\beta$ structures

From an electrostatic viewpoint, it is surprising that in proteins with alternating  $\alpha$ -helices and  $\beta$ -strands, the helices are roughly parallel, that is, with seemingly unfavourable helix dipole alignment. In studying this phenomenon electrostatically, we examined the arrangement of peptide units in parallel  $\beta$ -strands. From schematic drawings of hydrogen bonding patterns in parallel  $\beta$ -sheets (Fig. 2), it is obvious that the N $\rightarrow$  H as well as the C $\leftarrow$  O dipoles point backwards with respect to the N- to C-terminal direction of the strands. This suggests that the

parallel  $\beta$ -sheet has a significant overall dipole moment, with the N-terminal end of the strands corresponding to the positive end of the dipole. Quantitatively, about one-third of the peptide dipole is parallel to the strand direction. This allows an approximate description of a parallel  $\beta$ -strand as having 1/15 of a positive charge near the C-terminus (Fig. 2a). Electrostatically, then, the  $\alpha$ - $\beta$  dipolar interaction is favourable when helices and strands are antiparallel.

A second aspect of the electrostatic interaction between helices and sheets concerns the twist of the sheet<sup>23</sup>. A consequence of this twist is that the 'parallel' helices in the  $\alpha/\beta$  proteins make considerable angles (typically  $-40^\circ$ ; ref. 24) with each other, thus decreasing appreciably the unfavourable interaction between their dipoles (Fig. 1b).

We have calculated the actual  $\alpha-\alpha$  and  $\alpha-\beta$  dipole interactions in various  $\alpha/\beta$  proteins and the simple considerations above seem to be valid generally (Table 1). The negative values for  $U_{\alpha\beta}$  qualitatively confirm our hypothesis of a favourable strand-helix interaction. This interaction compensates fully or partly for the unfavourable helix-helix interaction (Table 1). In our energy estimates, we disregarded the difference in electrostatic screening near the surface and in the interior. As the parallel  $\beta$ -sheets are sandwiched by the helices, we have overestimated  $U_{\alpha\alpha}$  relative to  $U_{\alpha\beta}$  and so the actual total energies are probably more favourable. Thus, domain structures with parallel central  $\beta$ -sheets antiparallel to surrounding helices may be significantly stabilized by electrostatic interactions.

## All- $\beta$ proteins

In globular proteins containing only  $\beta$ -sheets, there is an overwhelming tendency for the strands to align in an antiparallel manner (ref. 7 and Table 2). The same seems to be true for fibrous  $\beta$ -sheet proteins<sup>25,26</sup>. Electrostatically, an energy

difference between the two kinds of pleated sheet may be related to the fact that in the antiparallel sheet all peptide dipole moments seem to cancel each other out: there is no residual moment in either direction (Fig. 2b). In the parallel arrangement the components of the dipole moment parallel to the strand direction interact unfavourably with each other. A simple model calculation, assuming only a dipole moment in the parallel strand and no dipole moment in the antiparallel strand, shows that this effect may be  $\sim 0.4$  kcal mol<sup>-1</sup> for a pair of short  $\beta$ -strands containing four residues. This gives a difference in electrostatic energy of  $\sim 0.8$  kcal mol<sup>-1</sup> between a parallel and antiparallel arrangement of three strands, which is much smaller than the energy difference for  $\alpha$ -helices, but it may nevertheless be significant.

#### The $\alpha_a \beta_a$ and larger proteins

A small number of proteins do not fall into the all- $\alpha$ ,  $\alpha/\beta$  or all- $\beta$  categories, for example the C-terminal fragment of the ribosomal protein L7/L12 (ref. 27), in which the three helices and three  $\beta$ -strands are optimally antiparallel to each other. The L7/L12 protein is very stable<sup>27</sup>—probably due not only to the close packing of nonpolar residues in its unusually hydrophobic core, but also to the optimally antiparallel alignment of secondary structure backbones embedded within that core. Proteins like L7/L12 can be described as  $\alpha_a\beta_a$ , whereas the 'classical'  $\alpha/\beta$  proteins may be coined  $\alpha_p\beta_p$  (a, antiparallel; p parallel). The all-helical proteins may then be described as  $\alpha_a$ , and the all- $\beta$  proteins as  $\beta_a$ .

In larger proteins a mixture of folding patterns occurs, for example, in p-hydroxybenzoate hydroxylase<sup>28</sup>. This protein consists of three domains which can be described as  $\alpha_p \beta_p$ ,  $\beta_a$  and  $\alpha_a$ .

In non-compact interfaces between subunits in oligomeric proteins, dielectric screening by the solvent will be much greater than in hydrophobic cores. Hence, preferred orientations for  $\alpha$ -and  $\beta$ -dipoles from different subunits are expected to be less pronounced.

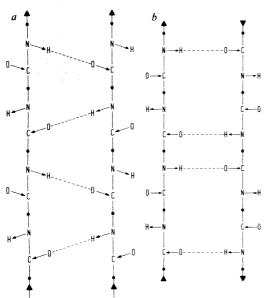

Fig. 2 Schematic representation of the arrangement of the  $N \rightarrow H$  and  $C \leftarrow O$  dipoles in  $\beta$ -sheets. a, Pair of parallel  $\beta$ -strands; b, pair of antiparallel  $\beta$ -strands. In parallel and antiparallel strands the  $N \rightarrow H$  and  $O \rightarrow C$  bonds have different directions relative to the strand direction. In the antiparallel case the bonds are fairly perpendicular to the strand direction, with little or no resultant dipole moment. In the parallel case, these bonds make angles of  $\sim 20^\circ$  with the N to C strand direction, thus about one-third of the peptide dipole moment runs parallel to the strand. Hence the component along the strand direction is  $\mu = 1/3 \, \mu$  (peptide) =  $1/3 \times 3.5 \, D = 1.15 \, D = 0.23 \, e Å$ . As the repeat distance along a  $\beta$ -strand is  $\sim 3.5 \, Å$  [refs 25, 76], a parallel  $\beta$ -strand can be considered as a dipole with a charge of +1/15 at its N-terminus and -1/15 at its C-terminus. Similar reasoning shows that the dipole of the  $\alpha$ -helix can be approximated by a charge couple of +1/2 and -1/2, respectively, at the N and C ends<sup>2</sup>. Thus on a per length basis, the  $\beta$ -parallel strand dipole is about a factor of five weaker than the helix dipole.

**Table 2** The predominance of antiparallel over parallel strand pairs in all- $\beta$  proteins and all- $\beta$  domains

Protein	Protein Strand pairs		Ref.
	$\beta_a$	$\beta_{ m p}$	
Elastase	11	0	59
Papain (domain II)	6	0	51

Acid proteases	7	2	74
Total	109	5	

All- $\beta$  proteins here includes those with a negligible number of helices.

#### Charged side chains

In addition to the interactions between secondary structure dipoles in the protein interior, electrostatic interactions of charged side chains with each other and with the  $\alpha$ -helix dipoles are another component of the total electrostatic energy of a protein molecule. This component will, in most cases, be less important than the interactions between the  $\alpha$  and  $\beta$  dipoles. Experimental evidence for this is provided by chemical modification studies in which the charge of exposed residues is removed or even reversed while the catalytic activity of the proteins is little affected<sup>29-31</sup>. In addition, comparison of different amino acid sequences which form strikingly similar structures shows little similarity in the position of residues of similar charge (for example, rhodanese<sup>32</sup> and the serine proteases<sup>33</sup>). A likely explanation for this is effective electrostatic screening of charged residues due to counterions and solvent dipoles<sup>34,35</sup>.

Flavodoxin probably has a significant electrostatic interaction between charged residues and  $\alpha$ -helix dipoles<sup>36</sup>. In this protein, the charged residues are distributed non-uniformly with respect to the helices:  $\sim 10$  negative charges occur near the N-termini of the helices without any oppositely charged side-chain partner nearby. The helices in this  $\alpha/\beta$  protein interact quite unfavourably (Table 1), and in this case the large number of favourable charge-helix dipole interactions compensates, together with the favourable  $\alpha-\beta$  dipole interactions, for the unfavourable helix dipole interactions.

The tropomyosin dimer, which is not a globular protein but forms a coil of two very long parallel helices of 284 residues<sup>37</sup>, shows the predominance of a large number of salt bridges over the interaction between the helix dipoles. As McLachlan and Stewart observed<sup>37</sup>, the charged residues in this protein are situated in such a way that like charges clash when forming antiparallel helices, but as many as 30 salt bridges can be formed in the parallel arrangement. As the helix dipole interaction does not increase after ~30 residues (Fig. 1d), the charge-charge interaction is now the major factor in determining the direction of the helices with respect to each other. However,  $\alpha$ -helical homopolypeptides, which lack such charge pairs (for example, polyalanine) actually seem to prefer an antiparallel arrangement, both in fibres and in lamellar single crystals 26,38, which is in complete agreement with the results of our model calculations (Fig. 1).

#### Conclusion

If the values of the electrostatic energies given in Table 1 are compared with the experimentally observed values of  $12\pm5$  kcal mol<sup>-1</sup> for the free energy difference between folded and

unfolded protein conformations<sup>39</sup>, it seems that the interaction between the main chain dipole moments of secondary structure elements has a significant role in determining the conformation of a protein molecule.

Our electrostatic considerations are also in accord with the frequent occurrence of  $\alpha\alpha$ ,  $\beta\beta$  and  $\beta\alpha\beta$  units in proteins<sup>7</sup>. The picture which emerges is that the interior of globular proteins is a medium with low dielectric screening in which the interactions between secondary structure dipoles lead to preferred folding patterns. Kauzman<sup>40</sup> suggested that hydrogen bonds between peptide links and hydrophobic interactions are the most important factors in determining the overall configuration of

# Clustered arrangement of immunoglobulin $\lambda$ constant region genes in man

# Philip A. Hieter\*, Gregory F. Hollis\*, Stanley J. Korsmeyer\*, Thomas A. Waldmann<sup>†</sup> & Philip Leder<sup>\*</sup>

\* Laboratory of Molecular Genetics, National Institute of Child Health and Human Development, and † Metabolism Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

The immunoglobulin  $\lambda$  light chain locus of man contains six  $\lambda$ -like genes arranged tandemly on a 50-kilobase segment of chromosomal DNA. The sequences of three of these genes correspond to three known non-allelic  $\lambda$  chain isotypes: Mcg, Ke<sup>-</sup>Oz<sup>-</sup> and Ke<sup>-</sup>Oz<sup>+</sup>. They surround a highly polymorphic and evidently unstable region that is repeatedly deleted when cloned in Escherichia coli. Three additional, but as yet unlinked, \( \lambda - like sequences have also been cloned, suggesting \) that the  $\lambda$  genes form an unexpectedly large family within the human genome.

THE formation of an active immunoglobulin light chain gene (k or  $\lambda$ ) involves the covalent joining of two distantly encoded segments of germ-line DNA<sup>1-5</sup>. In the case of the  $\kappa$  variable region of the mouse, V region diversity is accounted for largely by the availability of several hundred germ-line variable genes that can be joined to one of four active J region segments 8,9. The

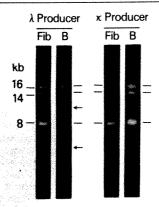

Fig. 1 Analysis of  $C_{\lambda}$  gene-bearing EcoRI fragments in human B-lymphocyte DNA. Light chain-expressing B cells (B) examined included monoclonal B lymphocytes, expressing  $\lambda$  or  $\kappa$  chain (as indicated) on their cell surface, taken from patients with high-count chronic lymphocytic leukaemia. Fibroblast (Fib) cell cultures served as germ-line controls for each individual. Genomic DNA was extracted from cells<sup>25</sup>, digested with EcoRI restriction endonuclease, size fractionated by agarose gel electrophoresis, transferred to nitrocellulose<sup>29</sup>, hybridized with  $^{32}$ P-labelled  $^{30}$  2.5-kb EcoRI-HindIII fragment obtained from the Hu $_{\lambda}$ 5 library clone (see Fig. 2 legend), and autoradiograms developed. DNA fragments identified in fibroblast DNA are indicated by thin lines; rearranged fragments in B-cell DNA by arrows. Identical results were obtained using as probe the subcloned 3.4-kb EcoRI-HindIII fragment obtained from the Hu $_{\lambda}$ 5 library clone (see Fig. 2).

precise cross-over point of this V-J joining can itself vary so as to create additional diversity around the site of recombination<sup>8-10</sup>. The arrangement of the human  $\kappa$  region gene is similar, but includes an additional active J region segment<sup>11</sup>.

The arrangement of mouse  $\lambda$  genes differs from that of  $\kappa$  genes in that the mouse  $V_{\lambda}$  repertoire is very small and only a single J region segment is likely to be encoded adjacent to each of the four known  $\lambda$  constant region genes 12.13. The human  $\lambda$  gene locus probably differs from that of the mouse as human antibody molecules are associated with a diverse population of  $\lambda$  chains, whereas mouse antibodies are not. Such a difference may reflect a much larger human  $V_{\lambda}$  gene repertoire. In addition, we have observed that there is a specific order of light chain gene recombination in which  $\kappa$  precedes  $\lambda$  14.15. The mechanism of this ordered rearrangement is unknown.

The human locus seems to be particularly favourable for examining the molecular basis for  $\lambda$  gene behaviour. The human  $\lambda$  constant region consists of at least four non-allelic forms that

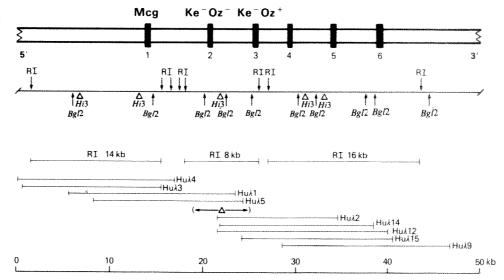

differ by limited amino acid substitutions to produce the serological markers Kern, Oz and Mcg (refs 16–19). Several additional  $\lambda$  variants have been recognized, but it is unknown whether these represent allelic variants or distinct isotypes<sup>20–22</sup>. Here we report the cloning and initial characterization of the germ-line  $\lambda$  constant region genes of man. These genes constitute an unexpectedly complex locus of at least six non-allelic genes that are arranged tandemly on a single chromosome. In addition, we have identified a polymorphic region within the locus that suggests a segment of particular genetic instability.

# Molecular cloning and identification of the human $\lambda$ constant region genes

To identify the human  $\lambda$  constant region genes, we used a mouse-human cross-hybridization strategy similar to that described for the identification of the human  $\kappa$  genes<sup>10</sup>. Our probe was a 0.24-kilobase (kb) MboII DNA restriction fragment derived from a mouse  $\lambda$ 1 cDNA clone (p- $\lambda$ -1; provided by A. Bothwell). This fragment corresponds to the gene segment that encodes amino acids 123 to 203 of the  $\lambda$ 1 constant region. The mouse  $\lambda$  constant region probe was used in conditions of low stringency to screen a human fetal liver library consisting of randomly cleaved DNA fragments cloned in bacteriophage  $\lambda$  CH4A (provided by T. Maniatis)<sup>23</sup>. In this way, seven distinct clones were obtained.

If the cloned fragments actually contained  $\lambda$  constant regions, we would expect them to hybridize to rearranged fragments of DNA in λ-producing B cells. We therefore examined DNA derived from  $\lambda$  light chain-bearing B lymphocytes obtained from a patient with high-count chronic lymphocytic leukaemia. (The leukaemic expansion of a lymphocyte is effectively monoclonal.) Subcloned fragments derived from one of the library clones were used as probes (Fig. 1). To control for possible polymorphic differences in the arrangement of hybridizing DNA fragments<sup>24</sup>, DNA extracted from fibroblast cultures established from the same individual served as a germ-line-like control. As shown in Fig. 1, the cloned probe detected two rearranged fragments in the DNA from the  $\lambda$ -producing B cells, whereas the DNA extracted from control  $\kappa$ -producing B cells demonstrated no such rearrangement. Note that the monoclonal λ-producing cells show rearrangement of two DNA fragments and that the 8-kb germ-line fragment has been lost in these cells. The most likely interpretation of this result is that rearrangement has occurred on both homologous chromosomes and that these rearrangements have occurred within or 3' to the 8-kb EcoRI fragment (see map, Fig. 2).

Fig. 2 Physical map of the human  $\lambda$  light chain constant region genes. arrangement of a cluster of six  $\lambda$  constant genes (filled boxes) along chromosomal DNA is shown at the top. The orientation is 5' to 3', left to right. A detailed map for the restriction enzymes EcoRI, HindIII and BglII is shown. The map was deduced by overlapping a series of library clones isolated from a human fetal liver DNA 3 and comparing cloned, genomic EcoRI fragments from that locus. Single and double restriction enzyme digestion patterns for EcoRI, HindIII, Bg/II and CfoI were compared and analysed for the presence of  $\lambda$  gene sequences by Southern Nine representative library clones (out of a total of 13) are shown. The library clones fell into two represented by clones 4, 3, 1, 5 and clones 2, 14, 12, 15, 9. Library clones that spanned the region indicated by  $\Delta$  invariably deleted extensive regions during propagation in the bacterial host. The unambiguous linkage between the two

groups of library clones was obtained by demonstrating that the restriction fragments generated from the cloned genomic 8-kb EcoRI fragment were identical to the sum of restriction fragments generated from an EcoRI-HindIII subclone of  $Hu\lambda 5$  plus a HindIII-EcoRI subclone of  $Hu\lambda 2$ . The library clones are represented by thin lines and designated as  $Hu\lambda$ . The genomic EcoRI fragments (RI) are represented by thin lines and their fragment lengths given. The three most 5' genes correspond to the non-allelic forms Mcg, Kern $^-Oz^-$  and Kern $^-Oz^+$ , as determined by nucleotide sequence analysis (see Fig. 4).

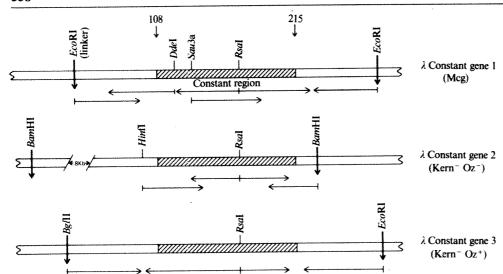

Fig. 3 Strategy for sequencing three human  $\lambda$  constant region genes. The coding regions of the three most 5' human  $\lambda$  constant region genes (genes 1-3, Fig. 2) were sequenced by the technique of Maxam and Gilbert<sup>31</sup> using the using the restriction sites indicated. The DNA restriction fragments used for (indicated bold bv sequencing arrows) were isolated preparatively on polyacrylamide gels as described previously 10. 32P ends are represented by short vertical lines and the extent and direction of sequencing are indicated by arrows. Hatched areas indicate coding regions (amino acids 108-215 of the  $\lambda$  polypeptide).

# Six λ-like constant region genes are arranged along a 50-kb segment of chromosomal DNA

Using the same human DNA fragments as probes, we rescreened the human clone library and obtained 19 distinct library clones (7 of which were identical to those obtained with the mouse probe, described above). In addition, the 8-, 14- and 16-kb genomic EcoRI fragments identified in Southern blots of genomic DNA (Fig. 1) were cloned directly using a fragment purification approach described previously<sup>25</sup>. By ordering the overlapping clones from restriction endonuclease site mapping data and Southern blot analysis (see Fig. 1 legend), we constructed the linkage map of the  $\lambda$  constant genes shown in Fig. 2. The map extends over 50,000 base pairs (bp) and contains at least six  $\lambda$  gene-like sequences tandemly arranged along the chromosome. The restriction enzymes EcoRI, HindIII, BglII and CfoI were used to establish the map. Thirteen of nineteen library clones overlap this locus; the remaining six clones are as yet uncharacterized. Six regions within this locus demonstrate strong homology by hybridization to the mouse  $\lambda$  constant region probe (data not shown). Note that these regions are regularly spaced along the chromosome ~5,000 bp apart.

# Identification of three additional $\lambda$ -like sequences

The order of genes (Fig. 2) allows us to predict that a V-J recombination event involving either gene 2 or 3 (on the 8-kb EcoRI fragment) should result in the deletion of DNA 5' to this fragment, in this case the 14-kb EcoRI fragment encoding gene 1. That this did not seem to occur in the  $\lambda$ -producing cell line used here (see Fig. 1) provided a clue that  $\lambda$ -like genes were encoded on two different 14-kb EcoRI fragments, one that fits into this map, and a second that does not. The non-allelic nature of the second fragment was confirmed by cloning it from two individuals and then showing that these separately cloned fragments, although identical to one another, were different from the originally cloned 14-kb fragment at several restriction sites (HindIII, BglII and CfoI, data not shown). We have not yet established the linkage relationship of the second fragment to the six clustered genes (P.A.H. and G.F.H., unpublished data). Indeed, careful examination of the  $\lambda$ -producing B cell in Fig. 1 shows a reduction of ~50% in intensity of the 14-kb fragment. This is consistent with the idea that both allelic copies of the 14-kb fragment encoding gene 1 have been deleted while both allelic copies of the second 14-kb fragment have been retained. In addition, we have cloned 16-kb and 5-kb Eco RI fragments of germ-line DNA that exhibit weak hybridization to the human and mouse  $\lambda$  constant region probes. Neither of these has been linked to the major six-gene cluster (G.F.H., P.A.H. and P.L.,

unpublished results). Whether these represent pseudogenes or functional coding segments is unknown.

# Sequenced genes correspond to specific human isotypes

To identify the  $\lambda$ -like regions (indicated in Fig. 2) positively as human  $\lambda$  constant genes, the nucleotide sequences of the three most 5' genes were determined using the sequencing strategy

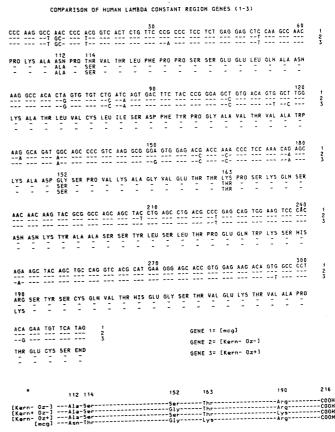

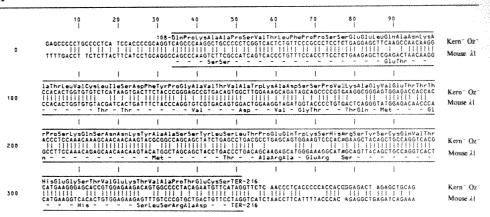

Fig. 4 Nucleotide sequences of three human  $\lambda$  constant region genes. The nucleotide sequences of the coding regions of the three most 5' genes (genes 1-3; see Fig. 2) are aligned. A dash in the nucleotide sequences of genes 2 and 3 indicates that the nucleotide in that position is identical to that in gene 1. The amino acid sequences deduced are shown below the nucleotide sequences. A dash in genes 2 and 3 indicates identity in that amino acid position to the gene 1 sequence. The amino acid sequence differences (positions 112, 114, 152, 163 and 190) between the four non-allelic forms of the human  $\lambda$  constant region are indicated at the bottom  $^{32}$ .

Fig. 5 Direct comparison of the nucleotide sequences of the human Kern  $Oz^-\lambda$  constant gene sequence and the mouse  $\lambda 1$  constant region sequences. The amino acid sequences deduced from the gene sequences are also shown. A dash in the mouse sequence indicates that the amino acid position is identical to that found in the human sequence. The frameshift mutation discussed in the text is at positions 253-270.

shown in Fig. 3. The nucleotide sequences corresponding to the amino acid coding regions are compared in Fig. 4 with their respective amino acid sequences.

At the protein level, at least four non-allelic forms of the human λ constant region have been identified <sup>16-19</sup>. The amino acid sequence differences between these are shown at the bottom of Fig. 4. By comparing these sequences with the amino acid translation of the three genes sequenced, we identify them as Mcg, Kern Oz and Kern Oz (Fig. 4). Presumably, one of the other genes—4, 5 or 6—corresponds to Kern Oz. The remaining two genes may represent additional non-allelic forms, may be separately encoded genes that are identical in their amino acid sequences to one of the four known non-allelic forms, or they may be pseudogenes. Direct nucleotide sequence analysis will distinguish between these possibilities.

#### **Evolutionary considerations**

The extremely close homology shown by the three sequenced genes suggests that they are the result of recent gene duplications. Single nucleotide differences are scattered throughout their coding regions, the fewest being in the carboxy terminal-coding portions. For example, genes 1 and 2 are identical in the 90 3'-terminal nucleotides of their coding sequences. There are four amino acid substitutions between genes 1 and 2 and 11 third-base silent mutations. Genes 2 and 3 differ by eight silent bases but only by a single amino acid substitution.

At the amino acid level, the human Kern Oz constant region is 72% homologous to the mouse  $\lambda$ 1 constant region, but only 61% homologous to the mouse λ 2 constant region. Therefore, it is reasonable to assume that the human genes have a more recent common ancestral antecedent with the mouse  $\lambda 1$  gene. To establish the nucleotide sequence relationships between the human and mouse  $\lambda$  constant genes, we have compared the Kern  $Oz^-$  nucleotide sequence with the  $\lambda 1$  constant region sequence of the mouse (Fig. 5)<sup>2,26</sup>. Strong homology extends throughout the coding region with single base differences being rather uniformly scattered. In the 315 nucleotides that comprise the coding block, 80 base substitutions have occurred. Thus the overall homology within the coding block at the nucleotide sequence level is 75%, which is greater than the homology observed between mouse and human k constant sequences . Base substitutions have occurred 19 times in the first position, 17 times in the second position and 44 times in the third position of amino acid codons, suggesting that selection occurs primarily on the basis of amino acid sequence. Curiously, one of these alterations has involved a compensating pair of single nucleotide insertion-deletion differences (positions 253 and 270; Fig. 5). A sequence characteristic of an RNA splice acceptor, PyPyXPyAg<sup>27</sup>, has been conserved in each sequence immediately 5' of the coding block.

# Restriction fragment length polymorphisms in the human $\lambda$ gene locus

During the isolation of cloned DNA sequences that spanned the region centred about the second and third genes (Ke^Oz^ and Ke^Oz^) we observed that these clones invariably deleted

extensive segments of DNA during propagation in the bacterial host. For this reason, our library clones fell into two groups that were difficult to link (represented by clones 4, 3, 1, 5 and 2, 14, 15, 9; Fig. 2). In fact, the definite linkage of these two groups had to be established by linkage of each to the cloned 8-kb EcoRI fragment (Fig. 2). Thus, there seemed to be an unstable sequence associated with this region at least as recognized by the bacterial host (designated by  $\Delta$  in the central 8-kb EcoRI fragment; see Fig. 2).

It was of interest to know whether this segment might also be unstable in man. Therefore, we prepared DNA from 15 individuals and used in situ hybridization to determine the arrangement of this fragment in this human population (Fig. 6). Even in such a small sample, we identified at least two, and possibly a third, arrangement of the  $\lambda$  constant genes within this fragment.

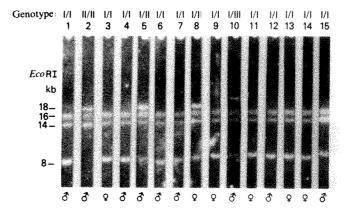

Fig. 6 Restriction fragment polymorphisms in the human C<sub>k</sub> locus. DNA was prepared from white cells isolated from 20 ml of blood taken from 15 individuals as follows: the cells were washed twice in ice-cold phosphatebuffered saline (PBS) and pelleted at 1,000 r.p.m. for 10 min. Red cells were lysed by adding 40 ml AKC lysing buffer (0.155 M NH<sub>4</sub>Cl, 0.01 M KCl) and left on ice for 10 min. White cells were pelleted at 1,500 r.p.m. for 10 min. DNA was extracted by resuspending the cells in 4 ml of 5% citric acid and breaking them with 10 strokes in a Dounce homogenizer (B pestle). Nuclei were pelleted by centrifugation at 2,000 r.p.m. for 5 min, then resuspended in 4 ml of 5% citric acid, layered over a 2-ml cushion of 0.88 M sucrose in 5% citric acid, and pelleted at 2,500 r.p.m. for 8 min. Nuclei were resuspended in 2 ml RSB (10 mM NaCl, 10 mM Tris pH 7.4, 25 mM EDTA) and diluted to 15 ml in RSB. Nuclei were pelleted and resuspended in 3 ml RSB. Proteinase K was added to a final concentration of  $10~\mu g~ml^{-1},~SDS$  to a concentration of 1%, and the mixture incubated at 37  $^{\circ}C$  for 2.5 h. The mixture was diluted to 5 ml in 0.5 M NaCl, extracted with phenol/chloroform/isoamyl alcohol (100:100:1) and centrifuged at 5,000 r.p.m. for 5 min. The aqueous phase was then extracted with ether, and precipitated by adding 2.5 vol ethanol. DNA was resuspended in 5 ml of 0.1 × SSC, digested with RNase (50 µg ml<sup>-1</sup>; 37 °C for 30 min), adjusted to 0.5 M NaCl, phenol and ether extracted as before, and ethanol-precipitated. The DNA was resuspended in 10 mM Tris pH 7.8, 5 mM NaCl, 0.5 mM EDTA and stored at 4 °C. Twenty ml of blood yielded ~400 µg of DNA. DNA (10 µg) was digested with EcoRI restriction endonuclease, size fractionated by agarose gel electrophoresis, transferred to nitrocellulese, hybridized to a human  $\lambda$  constant region probe (combined 1.2-kb BamHI-EcoRI fragment containing the Kern Oz C, gene and 0.8-kb BamHI-HindIII fragment containing the  $Mcg C_{\lambda}$  gene (see map, Fig. 2)), and autoradiographed. The lengths of the DNA fragments are indicated alongside. Three gene configurations were noted (types I, II and III) and are described in the text.

These polymorphisms represent differences in the lengths of the restriction fragments on which the λ constant genes Ke<sup>-</sup>Oz<sup>-</sup>(2) and Ke Oz+(3) reside. Case 1 is the most common genotype (type I), characterized by 8-, 14- and 16-kb EcoRI restriction fragments. Case 2 has a different genotype-in which an 18-kb fragment replaces the 8-kb fragment. Indeed, case 2 is homozygous for the 18-kb fragment as no 8-kb fragment is present in this individual. Case 5 represents an individual who is heterozygous for these alleles (type I/II). The allelism of these fragments has been further established by familial studies (P.A.H., G.F.H. and P.L., unpublished results). There is a third polymorphism (case 10, type III) associated with a 21-kb EcoRI fragment. As we have only one example of this type and because it retains at least one 8-kb fragment, we cannot be certain that the 21- and 8-kb fragments are allelic. The band intensity (Fig. 6) suggests, however, that this is the case.

Obviously these polymorphisms could arise either by point mutations or by rearrangements of large fragments of genomic DNA. The former mechanism seems less likely because it would require the alteration of several EcoRI sites to create an 18-kb (or larger) EcoRI fragment from the 8-kb fragment seen in type I (see map, Fig. 2). Rather, the labile behaviour of this fragment in E. coli suggests that it contains a 'hot spot' that readily deletes a segment of DNA. This, together with the frequent evolutionary rearrangement of DNA in higher organisms24,28, makes the rearrangement model a more attractive one.

#### Multiple $J_{\lambda}$ - $C_{\lambda}$ regions and $J_{\lambda}$ repertoire

We have already noted that there are several important differences in the germ-line arrangements of  $\kappa$  and  $\lambda$  genes, a main one (noted in the mouse) being that while there are at least four active J regions available for V-J recombination for the single  $\kappa$  region gene<sup>4,5,8,9</sup>, there is only one J for each of the mouse  $\lambda$  genes so far characterized 12,13. A priori, this would limit the diversity that could be generated through V-J recombination in the  $\lambda$  system if there was only one  $\lambda$  constant region. The complexity of the human and mouse  $C_{\lambda}$  loci suggests a mechanism that may compensate for this deficiency. Instead of creating a strip of J regions in front of a single constant region (as seen in the  $\kappa$  locus), the entire  $\lambda$  region in the mouse has been amplified to create four J regions, each associated with its own C region. The net effect is to make four J regions available in both the  $\kappa$  and  $\lambda$  systems. In the human  $\lambda$  gene system, the options for using each constant region may similarly depend on V-J recombination, but the complex organization of the locus allows us to consider subsequent recombination steps (akin to heavy chain switching) or even alternative modes of RNA processing as mechanisms for activating other  $J_{\lambda}-C_{\lambda}$  segments. The complete characterization of this locus and precise identification of its J regions will allow us to distinguish among these possibilities.

We thank Terri Broderick for help in preparing the manuscript and Barbara Norman and Marion Nan for assistance.

# Radio jet of 3C273

### R. G. Conway, R. J. Davis & A. R. Foley

University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL, UK

#### T. P. Rav

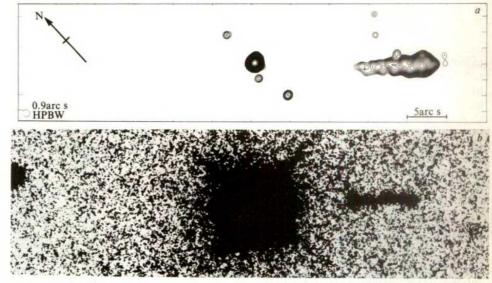

University of Manchester, Department of Astronomy, Manchester M13 9PL, UK

Most radio sources are two-sided, but a minority appear onesided, 3C273 being the first-known and brightest example. There is no agreement<sup>1-4</sup> on whether such sources are intrinsically one-sided, or are normal double sources, one half of which is hidden by Doppler effects. We report here new radio observations at 408 MHz of 3C273 which show that the brightness of the postulated counter-jet is <1/100 of the brightness of the visible jet. If this ratio is due to Doppler beaming, the source must be seen almost end-on, and the whole jet must be moving at a quasi-relativistic speed (>0.7c) into an ambient medium with number density <0.6 m<sup>-3</sup>. Because several arguments suggest that such a density is implausibly low, the jet of 3C273 cannot be identified with the radio lobe of a normal double source. If the emitting regions are moving slowly the ejection from the nucleus is certainly to one side only. An alternative possibility is that the jet is moving relativistically and behaves as one of the fast beams in the beam-model of Blandford and Rees5.

New radio observations of 3C273 at 408 MHz (λ0.735 m) made with the MTRLI<sup>6,7</sup> at Jodrell Bank are shown in Fig. 1a, along with a reproduction to the same scale (Fig. 1b) of an optical photograph<sup>8</sup>, taken in the blue-green. (The optical QSO is 13th magnitude, and has a redshift of 0.158.) In neither picture is there any evidence of a counter-jet, and from the radio map a limit of <1:100 may be put on the brightness ratio of the two sides. The lack of significant emission either at radio or optical wavelengths in the region out to 12 arcs. from the quasar is suggestive of an invisible beam5 of material with ordered relativistic motion or of photons carrying energy to the outer component. However, we cannot rule out an alternative explanation of the 'gap', namely that the output power of the quasar has decreased significantly during the past  $\sim 10^5$  yr.

The radio emission in Fig. 1a shows 'wiggles' or oscillations from side to side of the central ridge-line, a phenomenon first suggested by Conway and Stannard9, the general features of whose map we confirm. The wiggles are not accompanied by the oscillations in brightness which would be expected if they were due to precession of the source axis. We suggest that they are more probably hydrodynamic instabilities 10 of the jet as it traverses the intergalactic medium.

Table 1 lists some observed parameters of the radio emission, which yield physical quantities that can be compared with predictions from different source models, in particular the model with a relativistically moving counterjet, which is hidden by Doppler beaming. We have calculated the magnetic field and Fig. 1 a, The MTRLI map of 3C273 at 408 MHz (A0.735 m) tilted so that position angle 223° is horizontal. The contour levels are logarithmic, with three contours to a factor 2 in brightness, the lowest contour being 0.12 Jy per beam. The HPBW of the beam is shown as a circle 0.9 arc s in diameter in the bottom left corner. The 3% sidelobes north and south of the central quasar are artefacts due to calibration uncertainties, and may be ignored. b, Photograph by Arp (with the same scale as a). Seeing is about 1 arcs. Neither a nor b show any evidence for a counter-jet, and display a gap in emission out to 12 arc s. from the central nucleus. The optical jet appears to have an approximately constant brightness along its length with a possible knot of emission nearest the quasar,

whereas the radio brightness increases outwards by at least 100:1. The radio emission also displays 'wiggles' along the length of the tail. If  $H_0 = 100 \text{ km s}^{-1} \text{ Mpc}^{-1}$ , 1 arc s equals 1.85 kpc.

energy density in the head from the spectral index and brightness using standard synchrotron theory11. If there is equipartition of energy between the magnetic field and relativistic particles (the latter term divided equally between ions and electrons) and if the bulk motion is zero, the field B is 29 nT and the energy density  $u_{\rm obs}$  is  $680\,{\rm pJ\,m^{-3}}$ . Multifrequency measurements of the radio polarization of the jet (R.J.D., unpublished data) show that the emission depolarizes at  $\lambda \approx$ 0.73 m. If this depolarization is due to internal Faraday rotation by thermal matter<sup>20</sup>, then the electron density  $n_e$  within the jet is 11 m<sup>-3</sup>. (This value is unusually low. If the depolarization is external,  $n_e$  must be lower still.) The sound speed, equal to  $(\frac{1}{3}$  energy density/matter density)<sup>1/2</sup>, is calculated to be 0.29c. Such a value means that the jet must be confined sideways by some means, because if it were in free expansion, the opening angle of the jet would be much larger than is observed. This conclusion is not altered if the motion of the jet is relativistic.

VLBI measurements<sup>12</sup> have shown the presence of 'superluminal' proper motions in the nucleus of the quasar. According to the ballistic model (see ref. 2) the most probable value of  $\theta$ , the angle to the line of sight, is related to the true velocity  $\beta_n c$  by:

$$\beta_n = \cos \theta$$
 (1)

This condition also results in the maximum enhancement of proper motion<sup>2</sup>. If equation (1) is satisfied, and if Hubble's constant  $H_0$  is  $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$  (a value indicated by recent work<sup>13,14</sup>), then  $\theta \approx 11^{\circ}$ ,  $\beta_n = 0.983$  and the Lorentz factor  $\gamma_n = 5.4$ . We assume that the jet also lies at  $\theta = 11^{\circ}$ , in which case the length D from the nucleus to the outer head is 200 kpc. (If the 'light-echo' model is adopted<sup>15</sup>, then  $\theta = 22^{\circ}$  and D = 100 kpc.)

We assume that the forward speed of the jet is  $\beta c \leq \beta_n c$ , with Lorentz factor  $\gamma \leq \gamma_n$ . The blueshift factor is

$$\eta = \frac{\nu_{\text{observed}}}{\nu_{\text{emitted}}} = \frac{1}{\gamma (1 - \beta \cos \theta)}$$
 (2)

It can be shown<sup>2</sup> that the energy density in a moving jet needed to produce the observed brightness is

$$u_{\text{rest}} = u_{\text{obs}} \eta^{-(2+\alpha)4/7}$$
 (3)

The forward motion of the jet will be opposed by a ram-pressure force proportional to the number density  $n_{\rm m}$  of the medium in front of the head. For relativistic speeds the ram-pressure, referred to the rest frame of the head, is

$$P_{\rm ram} = n_{\rm m} \mu (\gamma \beta c)^2 \tag{4}$$

where  $\mu$  is the average mass per particle in the ambient medium. The motion will be decelerated unless  $P_{\text{ram}} \simeq \frac{1}{3} u_{\text{rest}}$ . From these equations,  $n_{\text{m}}$  may be found from the measured brightness as a function of the forward speed  $\beta c$ :

$$n_{\rm m} = 2.2 \ (\beta \gamma)^{-2} \eta^{-1.54} \ {\rm m}^{-2}$$
 (5)

This relation is shown graphically in Fig. 2.

If the absence of the counter-jet is due to Doppler beaming, then the speed required would be  $\beta > 0.7$  ( $\gamma > 1.4$ ), and the ambient density  $n_{\rm m} < 0.6~{\rm m}^{-3}$ . Such a low density is implausible because: (1) it is even lower than the universal density, estimated to be 10% of the closure density from quasar statistics<sup>16</sup>; (2) 3C273 is a member of a group of galaxies<sup>17</sup> where the expected density would be intermediate between the universal value and the value ( $\sim 10^{+3}~{\rm m}^{-3}$ ) found in large clusters<sup>18</sup>; (3) the formation of a group of galaxies and a massive quasar presents difficulties in a region with a very low density; (4) the sideways confinement of the jet requires a density several orders of magnitude higher than  $0.6~{\rm m}^{-3}$ .

The ram pressure argument may be used in reverse. If  $n_{\rm m}$  lies between the closure density ( $\approx 20~{\rm m}^{-3}$ ) and the upper limit of  $\sim 5,000~{\rm m}^{-3}$  set by X-ray observations (R. Willingale, personal communication), then the forward speed is in the range  $0.02 < \beta < 0.3$ . This value refers to the speed of the bow-shock in front of the head. In conventional radio source models much of the emission is from a 'working surface' moving at a speed close to that of the bow-shock. If this is the case in 3C273, a receding counter-jet with  $\beta < 0.3$  would be detectable well above our sensitivity limit, and we conclude that the ejection must be to one side only.

A source model with one-sided ejection (model A) still has unexplained features. Unless the temperature of the ambient gas exceeds 108 K, hydrostatic gas pressure will not confine the jet sideways, and some other mechanism must be cited to

Table 1 Observed parameters of 3C273

Projected separation between nucleus and head of jet 40 kpc Size of head 2.1 kpc  $\times$  1.1 kpc Apparent opening angle of jet 0.03 rad Spectral index  $\alpha(S \propto \nu^{-\alpha})$  0.7 Depolarization wavelength  $\lambda^{1/2}$  of head 0.7 Brightness temperature of head 2.4  $\times$  108 K

achieve confinement. A further consequence of model A comes from the following statistical argument (see Fig. 3 and ref. 4). If one-sided sources commonly consist of relativistically moving cores (emitting radiation beamed into a solid angle  $\sim \gamma^{-}$ together with slow-moving outer lobes emitting unbeamed radiation, then for every 'core-dominated' source, there should be  $\sim \gamma^2$  sources with a single lobe and little or no core. The total number of one-sided core-dominated sources exceeds 50 (I. W. A. Browne, personal communication) but no single example has yet been found of a one-sided source with no core. Hence, the motion in the core of a one-sided source cannot be at an appreciably higher  $\gamma$  than the motion in the outer lobe. If this argument is accepted, the superluminal velocity observed in the core of 3C273 cannot be interpreted as a ballistic motion, and must instead be a light-echo or similar effect.

We may avoid these conclusions if we assume that in 3C273 the radio radiation is not emitted from slow-moving regions such as the 'working surface', but instead is emitted directly from a fast beam, such as that proposed in the beam-model by Blandford and Rees<sup>5</sup>. We have explored a model along these lines (model B) in which the ejection is relativistic and may (but need not) be two-sided. The superluminal proper motion in the nucleus corresponds to true ballistic motion with  $\gamma \sim 5$ , and this velocity persists unchanged out to distances of 200 kpc (20 arc s) from the nucleus. Because of the high Doppler beaming factor  $(\sim 100)$  the radio emission from the fast beam will dominate over that from slow-moving material. However, the absence of a detectable counter-jet implies that the rest-frame luminosity of the fast beam is at least as great as that of the working surface, which would seem unlikely in view of the greatly increased turbulence at the working surface<sup>5</sup>. This difficulty is avoided if the ejection is one-sided even in model B.

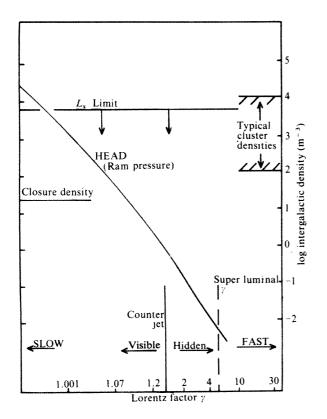

Fig. 2 The density of the intergalactic medium which will confine the head of 3C273 by ram-pressure as a function of forward speed, expressed as the Lorentz factor,  $\gamma$ , of the head. The actual function used is  $n_{\rm m} = 2.2 \ \beta^{-2} \gamma^{-2} \eta^{-1.54} \ {\rm m}^{-3}$ . The  $L_{\rm X}$  limit is provided by unpublished results from the Einstein satellite (R. Willingale, personal communication) and assumes a temperature of 108 K for the intergalactic medium. The speed at which an intrinsically equal counter-jet will be hidden by the Doppler effect is indicated, as is the value corresponding to the superluminal expansion

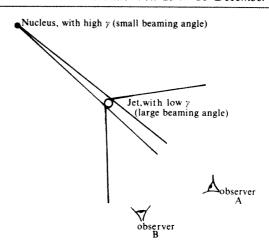

Fig. 3 Model for a radio source with a high  $\gamma$  in the nucleus and a low  $\gamma$  in the jet. Observer A sees strong radiation from both nucleus and jet. However a more typical observer B would see strong radiation from the jet but little radiation from the nucleus.

If the radio emission is from the fast beam directly, the beam must consist of relativistic particles, rather than photons. The thermal matter responsible for Faraday depolarization must not be co-moving, and hence cannot lie within the jet. It must form an irregular foreground screen, very possibly in the 'cocoon' region surrounding the beam. The front bow-shock moves slowly, and the ram pressure condition may be satisfied by the same values as in model A  $(0.02 < \beta < 0.3, 5000 > n_m > 20 \text{ m}^{-3})$ . There may be a difficulty with the power requirements in model B: to supply the fast-moving beam continuously requires at least  $5 \times 10^{38}$  W, which is 1% of the power output of the central quasar<sup>19</sup> and 100 times the emitted radio power.

The difficulties associated with these energy problems which are not unique to 3C273 have been discussed by Rees<sup>3</sup>. In the case of 3C273 the power flowing down the jet in the form of random particle motions is at least a factor  $100^{4/7}$  greater at the head than at the innermost end of the jet, which suggests that (in model B) the jet of 3C273 is not a continuous flow system.

We conclude that if the jet of 3C273 corresponds to the radio lobe of a normal radio source, then the emission is virtually unbeamed, and the ejection of material from the nucleus must be to one side only. Alternatively, the jet may be a visible example of a fast beam, such as that proposed in the beam model<sup>5</sup>, in which case the ejection may be two-sided, as Doppler beaming will suffice to hide the receding counterpart. Other factors have to be invoked, however, to explain the absence of unbeamed radiation from the radio lobe which such a fast beam would normally produce.

We thank Professor H. C. Arp for use of his recent photograph of 3C273. We also thank I. W. A. Browne and P. Birch for detailed discussions on relativistic beams. A.R.F. acknowledges an SRC research studentship.

#### Halo around the Crab Nebula

#### Paul Murdin

Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, East Sussex BN27 1RP, UK

#### David H. Clark

Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire OX11 0QX, UK

It has been argued that the supernova of AD 1054 which left the Crab Nebula supernova remnant was of Type II. Such supernovae occur in the spiral arms of galaxies and are believed to have initial masses of  $>4M_{\odot}$ . The helium overabundance detected in the Crab Nebula filaments is compatible with an initial stellar core mass of  $2-4\,M_{\odot}$  corresponding to a total precursor mass of  $10-15\,M_{\odot}$ . The Crab Nebula as usually depicted consists of filaments of total mass  $2-3\,M_{\odot}$  and a pulsar of  $1.4\,M_{\odot}$ . If the precursor of SN1054 was heavier than  $\sim 4\,M_{\odot}$ , its outer envelope could be detectable as an extended halo around the Crab Nebula. We have detected such an outer halo, whose size implies that the progenitor of SN1054 was indeed a massive star.

The observational material was a deep IIIaF plate obtained on 28 December 1976 from the 1.2-m UK Schmidt Telescope specifically to search for a halo around the Crab, and partly analysed but displaced from our attention by other interesting observations in June 1978. The exposure was through an interference filter with a 150 Å bandpass centred on  $H\alpha$ , and was calibrated with a step wedge illuminated with broadband red light. The calibration curve had to be extrapolated from densities  $\sim 0.3$  to the sky density  $\sim 0.2$ , very near the toe of the curve, and our estimate of the intensity of the halo must be treated with caution. An area  $40 \times 40$  times arc min around the nebula was scanned on the PDS microdensitometer at the Anglo-Australian Observatory and calibrated by the step wedge exposed on the plate. The point-spread-function (p.s.f.) of the instrumentation is shown by images of stars and has a circular disk ~1.5 mm (1.7 arc min) in diameter (caused by multiple reflections). Several star images showing this disk arising from a central density comparable with that deep within the nebula were also scanned in the PDS machine to determine the p.s.f. beyond the disk. It drops to zero (<1% of night sky brightness) at 2 arc min radius from the stars.

The elliptical image of the Crab Nebula has a bright central area of 7 arc min major axis by 4 arc min minor axis, in accord with the dimensions derived by van den Bergh<sup>3</sup>. Beyond this abrupt boundary is a halo whose brightness falls to the night sky background at a distance from the centre of the nebula of 6 arc min along the minor axis direction (Fig. 1) and 14 arc min along the major axis direction, well beyond the tail of the p.s.f. The dimensions of the halo are thus three to four times that of the nebula.

The surface brightness of the halo is  $\sim 2\%$  of the night sky intensity. At Siding Spring, Bessell<sup>4</sup> measured the *R*-band sky brightness at 21.9 mag arc s<sup>-2</sup>. The night sky brightness is a variable reference, depending on season and solar cycle, but through the filter the Crab halo brightness is  $\sim 2 \times 10^{-7}$  erg s<sup>-1</sup> cm<sup>-2</sup> sr<sup>-1</sup>. This corresponds<sup>5</sup> to an emission measure for the H $\alpha$  intensity of  $\sim 7$  pc cm<sup>-6</sup>, with an uncertainty of a factor of two, corresponding to errors in the plate calibration and reference source.

A thermal soft X-ray enhancement peripheral to the nebula has been detected<sup>6</sup> from a lunar occultation observation of the Crab. Imaging soft X-ray observations from the Einstein Observatory have failed to confirm the reality of the halo because of the problems of scattering of the intense nebular

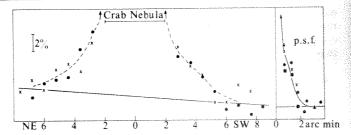

Fig. 1 Two surface brightness profiles (● and ×) along the minor axis of the Crab Nebula. The profiles are from parallel strips 1.6 arc min wide lying either side of the minor axis. The Crab Nebula has a bright central area 4.0 arc min in minor axis, with a halo extending 4 arc min beyond this. Also shown is the point-spread function of the instrument and measuring technique. The night-sky background under the Crab Nebula shows a slope up to the Milky Way in the north-east.

emission from the telescope mirror; modelling of this scattering may yet reveal a residual halo (F. Seward, personal communication). An optical halo extending 20% further from the centre than the abrupt edge of the filaments has been detected by Scargle<sup>7</sup> in the continuum bandpass 530–590 nm, and attributed to leaking electrons and magnetic fields, yielding extended synchrotron emission. As the halo we have detected through the  $H\alpha$  filter extends further and appears to be stronger we attribute it to  $H\alpha$  emission, and Scargle's halo we suppose to be weak line emission.

The origins of nebula and halo are proposed to be the following<sup>1</sup>. The core collapse deposited  $\sim 2 \times 10^{51}$  erg in the helium-rich outer core, which, expanding outwards, was decelerated, thus setting up a high-pressure region. consequent reverse shock wave drove the core material back to the centre. As the original deceleration was Rayleigh-Taylor unstable, some mixing of outer-core and envelope is expectedonly  $0.5 M_{\odot}$  of mixed envelope material is required to provide the observed nebula abundances1. The bulk of the supernova energy was transferred to the outer envelope of the presupernova star. On this model the observed nebula is the outer core-envelope mixture, whose present kinetic energy has been derived almost entirely from the pulsar, and the postulated halo is high-velocity low-density material from the envelope of the precursor. A consequence of such an interpretation is that the near coincidence between the supernova in history and the proper motion age for the nebula is merely coincidence.

An alternative explanation for the halo is that it represents light scattered off dust grains surrounding the Crab. These may have been produced by the precursor (an alternative indication that it was massive) or be swept-up interstellar material (J. C. Wheeler, personal communication) even at the low ambient interstellar density near the Crab ( $z \sim 200$  pc above the galactic plane).

The size and brightness of the observed optical halo compare well with the properties of the outer shell of the Crab predicted by Chevalier<sup>1</sup>. He calculated that a shell moving at  $5,000~\rm km~s^{-1}$  would have a size R four times the radius of the Crab. We observe a halo 3-4 times the Crab radius. If the shell was of mass  $M=10~M_{\odot}$ , mean density 1 atom cm<sup>-3</sup>, it would be fully ionized by the Crab's synchrotron radiation and have an emission measure of 5 pc cm<sup>-6</sup>. We observe  $E\sim7$  pc cm<sup>-6</sup>. Thus the halo we observe may be slightly more compact and brighter than the prediction. The mass in the shell is most sensitive to the extent of the halo: M scales as  $E^{1/2}R^{5/2}$ , yielding  $M\sim8M_{\odot}$ , so Chevalier's prediction is satisfactory. Adding filaments and pulsar, the precursor mass was about  $12~M_{\odot}$ .

The above calculation is based on the hypothesis of a uniform shell density. M is overestimated if the shell is lumpy or structured. The lack of granularity and the lack of peripheral brightening in the shell we observe are surprising but a massive progenitor would be expected to experience significant massloss before it went supernova and a substantial density gradient surrounding the expanding envelope might explain the observed

brightness distribution. In view of uncertainties in the model, in the reference intensity of the night sky and in the calibration of the plate, our estimate of the Crab precursor's mass of  $12 M_{\odot}$  is indicative only.

Observations of the halo, such as photoelectric confirmation of its extent, distribution and brightness, spectral confirmation of its emission spectrum and detection of its anticipated large velocity dispersion, and polarization measurements are needed to elucidate its nature.

We thank Peter Krug for measuring the plate, which was obtained by Tim Hawarden.

### Spin directions of interfering beams in quantum interferometry

#### A. Zeilinger\*

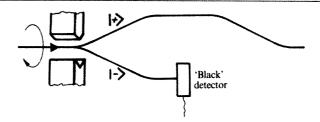

Atominstitut der Österreichischen Universitäten, A-1020 Wien, Austria

It is shown here that, in a fermion interferometer experiment, the notion of the relative orientation of the interfering beams can be given a sensible meaning—information may be extracted about the spin directions without destroying the interference pattern. This is done on a gedanken-experiment level by introducing into, say, a neutron interferometer Stern-Gerlach magnets with detectors placed into their respective 'down'-spin beam paths. Similar considerations apply to experiments where spinor behaviour has been demonstrated in systems with higher spin.

In interferometry experiments with non-zero spin particles interesting effects arise due to the wave function (or probability amplitude) of the interfering beams being nonscalar. One effect concerns the sign change of a spinor wave function under  $2\pi$ -rotations<sup>1,2</sup>. This was verified by neutron interferometry experiments<sup>3-7</sup>, in which an incident beam was split coherently into two wave trains one of which was passed through a static magnetic field where it experienced Larmor precession and hence spin rotation. The spinor property was then found as a variation of the intensity of the recombined beams with a fringe period of multiples of  $4\pi$  of the rotation angles. The values of the rotation angles were calculated from the magnetic field strengths using the known value of the neutron magnetic moment.

The interpretation of this type of experiment has been widely debated<sup>8-12</sup>. Moore<sup>8</sup>, in discussing Bernstein's proposal<sup>2</sup> to use Larmor precession to implement the desired rotation, claims that in this experiment it would not be possible to observe directly that anything is actually rotating.

Byrne<sup>9</sup> has explicitly demonstrated the differences between spinor and vector wave interferometry. He showed that, in a spinor experiment, it is not possible to observe simultaneously the interference pattern and to obtain information about the relative spin directions of the constituent beams from measurements on the recombined beam. Byrne concludes that the notion of relative rotation ceases to have a meaning as it corresponds to nothing which is measurable. Thus he dismisses the interpretation that the experiments have provided a direct observation of the sign reversal of a spinor wave function subjected to a  $2\pi$  rotation as unsatisfactory because, for any

Modified Stern-Gerlach arrangement with a black detector in one beam path.

fermion the relative rotation of the spins in the two beams and the interference pattern are mutually incompatible observables.

However, it is possible to conceive of experimental schemes where information may be extracted from the beams interfering about their spin directions without destroying the interference pattern. In our experiments unpolarized incident neutrons were used for intensity reasons only. We consider here polarized incident neutrons that are able to trace the behaviour of the interfering spin states.

We look for a measurement procedure which changes neither the amplitudes nor the relative phase of these beams—a measurement without wave packet reduction. In quantum mechanics, such a measurement is possible if the quantum system under investigation is in an eigenstate of the observable defined by the measuring apparatus. For spin measurement, we consider for example, a Stern-Gerlach experimental arrangement in which we place into one of its separated beam paths a black (100% absorbing) detector (Fig. 1). To restore the beams to their initial paths, we place behind the first Stern-Gerlach an inverted second one. If the incoming beam is in the eigenstate corresponding to the detector-free path no event will be registered in the detector. The restriction that the amplitude at the detector never vanishes exactly due to the nonlocality of wave packets, can be reduced by increasing the separation of the beams. Similar considerations apply to the non-existence of exactly 100% absorbing detectors. Thus, the result that we did not register events in the detector together with the knowledge that particles have passed through the Stern-Gerlach gives us information about the spin observable of the incident beam.

In the more general case where a spin rotation device is placed in front of the Stern-Gerlach, the particles are no longer in an eigenstate of the Stern-Gerlach. Therefore, events will be registered in the detector. For simplicity we assume the incident beam to be polarized in a direction normal to its propagation direction and the magnetic field to rotate the spin around that propagation direction. The spin direction of the beam can then be found by rotating the Stern-Gerlach around the neutron propagation direction to that angular position where the counting rate in the detector vanishes. This spin direction is a macroscopically observable quantity—the angular position of the Stern-Gerlach. Many other geometrical arrangements can be envisaged on a gedanken-experiment level because for slow particles such as thermal neutrons the spin can be made to point in any direction relative to the propagation direction.

Formally we may describe our arrangement by a projection operator of the form  $P = |s\rangle\langle s|$ , where  $|s\rangle$  is the +eigenstate of the Stern-Gerlach. If that operator acts on the incident state |s>, that state is reproduced.

In an interferometer experiment of the type shown in Fig. 2 an incoming wave is split into two partial waves by a semireflecting mirror. These waves follow two distinct paths within the interferometer. Furthermore, in one beam path a magnetic field is arranged to rotate the spins. To observe the spin directions of these interfering beams we place a modified Stern-Gerlach arrangement into each interferometer beam path. In both arrangements we again place a detector into one of its beam paths, say, the 'down' spin beam path, leaving the 'up' beam path through each Stern-Gerlach free. If we start the experiment with arbitrary angular settings of the analysing direction of the Stern-Gerlach magnets we will again register particles in

<sup>\*</sup> Present address: Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

the detectors. The count rate in each detector will be lower in the interference experiment because the amplitude of each separated interferometer beam is lower than the amplitude of the incoming wave. But the fact that particles are registered means that the corresponding partial wave is not in the 'up' eigenstate of the Stern-Gerlach in that partial beam.

Both Stern-Gerlachs are now rotated independently of each other until we arrive at a position where neither detector registers a single event. At that point, the amplitude of the corresponding partial wave in the 'down' eigenstate of the Stern-Gerlach vanishes. However, we can still observe the interference pattern of the recombined beams, because our Stern-Gerlach arrangement does not enable us to determine which path is followed by the particle in the interferometer. Hence, both the null-effect spin measurements and the interference fringe observation allow us to conclude that the particles are in a coherent superposition of the two 'up' states defined by the two different Stern-Gerlachs. Or  $|\psi\rangle = |S_1\rangle + |S_2\rangle$ , where  $|S_1\rangle$  and  $|S_2\rangle$  are the 'up' eigenstates of the Stern-Gerlachs in the beam paths 1 and 2, respectively.

As the analysing directions of the Stern-Gerlachs are macroscopically observable quantities we conclude that the relative spin directions of the interfering beams are operationally meaningful quantities. This also applies to the relative rotation of the interfering beams because, in principle, we can trace the effect of the spin rotation device in arbitrarily small steps. We still have to consider whether the introduction of our spin-measurement devices may destroy the relative phase of the interfering beams.

Nevertheless, when considering—on the gedanken-experiment level—the use of the Stern-Gerlach magnets the inhomogeneous magnetic fields may lead to a destruction of the coherence of the interfering beams<sup>13</sup>. But other spin measurements can be envisaged where this is not the case. For thermal neutrons, diffraction at perfect crystals in external homogeneous magnetic fields<sup>14</sup> and refraction at wedge-shaped magnetic fields<sup>15</sup> both lead to a separation of the spin states while retaining their coherence properties. These schemes also offer the advantage that in contrast to a gedanken-experiment they are actually realizable experimentally along the lines of the existing technology of perfect crystal neutron optics.

At about the same time that the neutron interferometer experiments were performed it was realized  $^{16}$  that the spinor behaviour can also be observed in a spin 1 system. This exploits the fact that the wave function of a two-state system—except for the photon and similar degenerate cases—changes sign under a  $2\pi$  rotation. Thus, if in a three-state system the populations of two levels are inverted twice by properly phased electromagnetic high frequency pulses, their state function acquires the -1 phase factor. That phase factor may be revealed by observing interferences between one or both of these two states and the third state. There is also experimental evidence  $^{16}$  for that

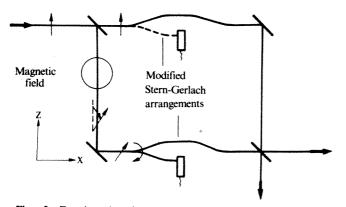

Fig. 2 Fermion interferometer gedanken-experiment with modified Stern-Gerlach arrangements in both beam paths. The magnetic field produces a spin rotation around the x-direction. A corresponding rotation of the lower Stern-Gerlach ensures unattenuated passage.

behaviour based on radio-frequency transitions between hyperfine energy levels in TIF. The same effect can be demonstrated experimentally by exploiting NMR transitions  $^{17-19}$ . There, systems can be found where a continuous transition between spin  $\frac{1}{2}$  and spin 1 behaviour may be seen depending on a continuous variation of the relative amplitudes of excitation of transitions between 2 or 3 levels.

Even for the above type of experiment we could consider a spin direction which is rotated while the relative population of two levels is changed. To apply our spin-measurement scheme we consider, again on a gedanken-experiment level, a further Stern-Gerlach magnet which separates spatially all three incoming states. Later while one of these states is left unaffected we may recombine the other two states and subject them to the same measurement procedure as above. Thus we may introduce transitions between these two states and we may use one of our modified Stern-Gerlach arrangements to determine the spatial direction for which this two-state subsystem is in an eigenstate. After recombination with the unaffected third state the interference effects may still be observed. Thus, here too it is possible to assign a meaning to the notion of a spatial direction, the rotation of which is associated with the  $4\pi$  periodicity of the phase factor.

The approach presented here is to some extent complementary to Renninger's considerations of a measurement without disturbance of the measured system<sup>20</sup>, a concept which has been extended to the spin case by Yoshihuku<sup>21</sup>. The difference is that in Renninger's case the wave packet is actually reduced by the measurement while we consider a measurement without wave packet reduction. Note that there exists a non-vanishing probability that in our modified Stern-Gerlach experiment we may not observe particles in the 'down' detector even if the spin is not in the 'up' eigenstate of the Stern-Gerlach. Evidently that probability can be reduced by increasing the number of particles passing through the apparatus and by carefully orienting the direction of the Stern-Gerlach. Therefore the spin direction can only be determined within a certain error. Our gedankenexperiment shares this this inherent statistical nature with other quantum measurements and, to some extent, with classical measurements. Nevertheless, in an interferometer experiment this is a minor point as our modified Stern-Gerlachs actually produce the beams in their respective 'up' eigenstates: the down' states are absorbed by the detectors.

The action of our modified Stern-Gerlach magnets including the absorbing detector in one beam path can be described by the projection operator

$$P_{\rm Op} = \frac{1}{2}(I + \mathbf{n}\sigma) \tag{1}$$

Here,  $\mathbf{n}$  is a unit vector pointing in the analysing direction of the Stern-Gerlach and  $\boldsymbol{\sigma}$  is the Pauli spin matrix vector. A state is in the 'up' eigenstate of the Stern-Gerlach if

$$\psi = P_{\mathrm{Op}}\psi \tag{2}$$

If we write  $\psi$  as the spinor

$$\psi = e^{i\xi} \left( \frac{a}{h e^{i\phi}} \right) \tag{3}$$

Equation (2) implies that

$$\mathbf{n} = (2ab\cos\phi, 2ab\sin\phi, a^2 - b^2) \tag{4}$$

that is **n** has to coincide with the polarization direction of the particles described by  $\psi$ .

Disregarding the details of the physics of the beam splitters we can use phenomenologically for the beams inside the interferometer the four-component spinor

$$\psi_{1F} = \begin{pmatrix} \psi_{1}^{+} \\ \psi_{1}^{-} \\ \psi_{2}^{+} \\ \psi_{2}^{-} \end{pmatrix} = e^{i\xi} \begin{pmatrix} a_{1} \\ b_{1} e^{i\phi_{1}} \\ a_{2} e^{i\chi} \\ b_{2} e^{i(\chi + \phi_{2})} \end{pmatrix}$$

where, say,  $\psi_1^+$  is the amplitude in the +z-direction in beam 1 and so on. The normalization condition is  $a_1^2 + b_1^2 + a_2^2 + b_2^2 = 1$ . This four-component spinor describes the states inside the

interferometer, the beams leaving the interferometer are superpositions of its various amplitudes.

In analogy with the above case, the projection operator describing the case where two modified Stern-Gerlachs are in the interferometer, one in each beam path, may be given as

$$P_{\rm IF} = \frac{1}{2} \begin{pmatrix} I + \mathbf{n}_1 \boldsymbol{\sigma} & 0 \\ 0 & I + \mathbf{n}_2 \boldsymbol{\sigma} \end{pmatrix} \tag{6}$$

The condition that this operator leaves the wave function invariant

$$\psi_{\text{IF}} = P_{\text{IF}} \psi_{\text{IF}} \tag{7}$$

implies again that

(8

Or, equivalently, the analysing directions of the individual Stern-Gerlachs have to be oriented parallel to the respective beam polarization directions. The particle state is then left invariant, in particular the relative phase  $\chi$  in equation (5) between the two interferometer beams is unchanged. Therefore the interference pattern may still be observed.

Colon<sup>1</sup> and Ramage<sup>2</sup> have investigated the thermal stratification of the summer monsoon air and presented evidence of a welldefined temperature inversion in the lower atmosphere over the Arabian Sea. This inversion is low (base between 900 and 800 mbar) and strong over the western Arabian Sea and weakens and rises (base at ~700 mbar) towards the coast of India and is not observed east of 70°E, especially during the active monsoon3. The presence of dry warm continental air from Africa and Arabia above the maritime air is thought to be associated with this inversion. This inversion is very important to the rain producing potential of the monsoon current because once the inversion is destroyed there is a favourable stratification for rapid release of moisture upwards leading to precipitation. Observations of the western Arabian Sea inversion features have previously been reported only from in situ ship radiosonde and aircraft dropsonde measurements. Although the basic accuracy and the vertical resolution of the present-day satellite sensors cannot delineate the small-scale variations of temperature4 such as monsoon inversions we have detected these features from just the TIROS-N derived seasurface temperatures and the 1,000-850 mbar layer-mean temperatures using a simple differencing procedure. From these temperatures and simultaneous satellite-derived mid-tropospheric water vapour content, we show here the close link between the extent of inversion regions and the convective processes with the Indian monsoon at its different phases.

The present data pertain to the Monex-period (1 May-31 July 1979) TIROS-N satellite results of 14.00 h LT supplied by NOAA Environmental Satellite Service of the USA. These results (about one set in a 2.5° × 2.5° lat.-long. box) include data on the: sea surface temperature (SST); 15 layer-mean atmospheric temperature profile from 1,000 to 0.4 mbar; and 3 level total water vapour content.

The inversions are characterized by the altitude of its base, height extent and temperature departure. Well-marked (height extent >30 mbar and temperature departure >3 °C) monsoon inversions in the western Arabian Sea exhibit in the aircraft dropsonde profiles a negative lapse rate in the altitude regions between 900 and 800 mbar region, above and below which the lapse rates are similar to those of the normal profiles.

Our investigation did not reveal any inversion features from the individual temperature profiles of the satellite data set. However, we now use only the SST and the lowest layer-mean (1,000-850 mbar) temperature, referred to as  $T_1$  and  $T_2$ respectively.

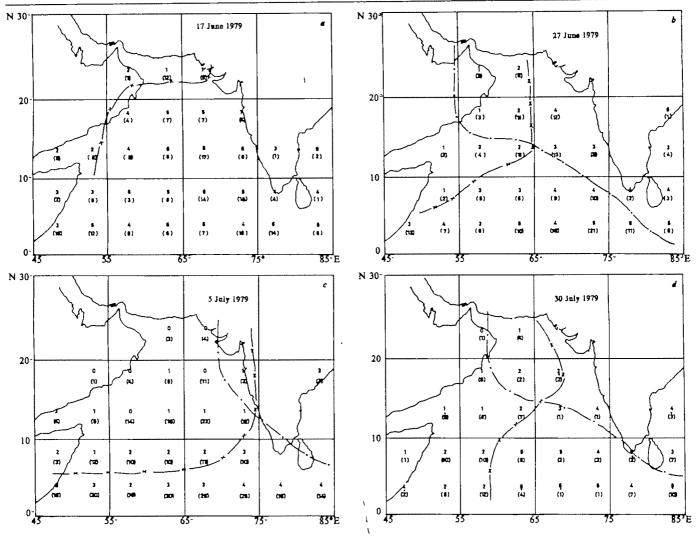

For a temperature profile with an inversion structure at lower levels (below 850 mbar), the layer-mean temperature of the 1,000-850 mbar layer will be larger than that for normal profiles (those which follow a standard lapse rate with height). Assuming further that the sensible heat exchange between the sea and the air above is small and fairly uniform<sup>5</sup> (implying small air-sea temperature difference), it is to be expected that a horizontal map of the difference,  $\Delta T$ , of the satellite-derived SST  $(T_1)$  and the 1.000-850 mbar layer-mean temperature  $(T_2)$ , with appropriate time and spatial averaging could reveal the inversion regions. Lower values of  $\Delta T$  can be interpreted as being associated with regions of inversion. From in situ aircraft dropsonde measurements, the values of  $\Delta T$  for non-inversion profiles in the active monsoon areas range between 4 and 6 °C and in inversions these are as low as 0 °C in some cases.

Examination of the horizontal variation of the  $\Delta T$  values thus obtained from satellite data also minimizes the errors that may be present in the original temperatures  $T_1$  and  $T_2$ , whose retrieval involves assumptions of the atmospheric models in the radiative transfer computations.

The aircraft dropsonde measurements during Monex 1979 provided data for in situ ground truth comparisons in the Arabian Sea between long. 75° E and 55° E. However, these measurements were available up to 27 June 1979 covering only the onset and active periods of the monsoon. No in situ data

were available for break and revival periods. The *in situ* information available has been used to define inversion regions (up to 850 mbar) in the Arabian Sea.

A total of 85 and 74 aircraft profiles during the onset and active phases respectively were used for comparisons with the satellite data. A fairly large number (20) of well-marked inversions were available only from the profiles of 27 June. The comparative study indicates that inversion-free (up to 850 mbar) regions, as evidenced from dropsonde data, were associated with satellite  $\Delta T$  values of 3 °C or more, and well-marked inversion profiles were associated with  $\Delta T$  values of 2 °C or less.

Table 1 shows that with a high reliability the  $\Delta T$  values can be used to determine the existence or otherwise of the inversion regions. These comparisons (and the results) indicate that the  $\Delta T$  variations inferred from our method could be considered accurate to 1°C.

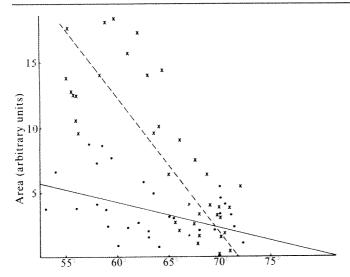

We also attempted to look for inversions above 850 mbar by employing the  $\Delta T$  maps derived from the 1,000–850 and the 850–700 mbar layer-mean temperature values. No significant horizontal variations of  $\Delta T$  were observed, indicating that these are either weak, less in height extent or non-existent. The detection of inversions in these regions would need much refined satellite measurements.

The *in situ* statistics of the aircraft dropsonde profiles were used to interpret all available results and  $\Delta T$  values of 2 °C or less have been delineated as regions associated with inversions.

The data at any particular location for any individual day were insufficient for our analysis, mainly due to a large underlap in the tropical regions of about  $8-10^\circ$  in latitude between successive satellite passes, the swath itself being  $\sim 10^\circ$  lat., the other major limitation was the cloud cover which inhibited proper temperature retrievals. To help overcome these limitations we adopted a spatial (a  $5^\circ \times 5^\circ$  lat.-long, grid box) and time-averaging procedure to investigate the inversion regions in the temperature fields. These optimal nesting and averaging schemes were arrived at from a preliminary examination of the day-to-day plot of the satellite temperature maps and a consideration of the large time and spatial scales associated with the monsoon inversions.

Figure 1 presents the  $\Delta T$  maps during the different phases of the monsoon of 1979. Values of  $\Delta T$  indicated over land correspond to the  $5^{\circ}\times 5^{\circ}$  box central location. The contribution is due entirely to those soundings from over the sea. A feature which persists throughout the observational period is the tendency of  $\Delta T$  values to increase slowly from west to east as the monsoon becomes established.

The map of the pre-onset time (not reproduced here) shows  $\Delta T$  values at all places more than 3 °C indicating no inversion features. Figure 1a shows the inversion being set up in the western Arabian Sea at the onset time of the monsoon. The low  $\Delta T$  values start covering a larger part of the Arabian Sea (but confined still to west of 65° E) at the most active phase of the monsoon (Fig. 1b). These results agree with those reported by

Strength of inversion at onset and active phases from in situ –, Onset phase (●); – – –, active phase (×).

Sen and Das<sup>6</sup> and Ghosh et al.<sup>3</sup>, who have shown from limited Monex (1979) and Ismex (1973) in situ data respectively, that the inversion regions are confined to west of 65° E during the active periods.

The area included between the normal profile (with standard lapse rate) and the observed profile (with or without inversion) is a good in situ measure of the inversion strength, as it incorporates both the height extent and temperature departure features of inversion. Figure 2 shows a scatter plot of the area so calculated between surface and 700 mbar for the in situ dropsonde profiles for the onset and active periods. The gradual increase of area from east to west and a sharp increase of the slope from the onset to the active phase as revealed by in situ observations of this plot agree well with similar features revealed by the satellite  $\Delta T$  maps (Fig. 1a, b).

We also report here observations of the inversion features available from the  $\Delta T$  maps during the weak and the revival phases of the monsoonal activity. No observations in situ or otherwise have previously been reported of the inversion features during these periods of the monsoon. Our analysis shows that during times of weak monsoon activity the inversion regions intrude east of 65° E (Fig. 1c) and even encroach the west coast of India. The revival of monsoon after 29 July is revealed by the  $\Delta T$  map (Fig. 1d), with a shifting to the west of  $\Delta T$  values, and these being 3 °C or more east of 65° E.

Figure 1b-d also shows the 10-mm total water vapour content contour corresponding to the 700-500 mbar level drawn from the data of the TIROS-N observations. East of this contour the values are higher and to the west lower than 10 mm. Figure 1b-d reveals a clear oscillation from west to east and then back to west longitudes of this contour between the active, weak and revival phases of the monsoon.

We have not observed such clear oscillations of the lower level (1,000-700 mbar) water vapour content contours. The observation of the middle level moisture content and its change during the different phases of the monsoon (illustrating the convective activity) are consistent with our observations of the east-west shifts of the low level inversions, and show the close link of these two phenomena with the general monsoon circulation.

We thank Dr T. A. Hariharan, Head, Meteorology Division, for encouragement and guidance; also Professor J. N. Desai, Drs P. S. Sehra and P. S. Desai for useful discussions.

### Steady-state magma discharge at Etna 1971–81

#### G. Wadge

Throughout the past decade Mount Etna has been in almost continuous activity and even during periods of repose incandescent lava has often been visible in at least one of the summit vents. Using observations by Italian, British and French volcanological teams we have estimated the volumes of lava produced by each eruption from 1971 to July 1981. The computed output of magma for this period approximates to a rate of 0.7 m<sup>3</sup> s<sup>-1</sup>. We now compare this with our output rate estimates for Etna's historic past. The steady-state nature of the output during the past decade has implications for the interpretation of the volcano's internal plumbing and the petrology of its lavas, and the assumption that this state will be maintained allows us to discuss the timing and magnitude of future erup-

In 1975 we presented evidence<sup>1</sup> for the rate at which magma appears at the summit and at the flank vents of Etna during the period 1966-74 and for the rate at which it erupted solely on the flanks of the volcano over a longer period (1535-1974). We now extend this record of volumetric discharge of magma to July 1981 (Table 1).

During the period 1971-July 1981 there were six eruptions involving flank vents (1971, 1974, August 1978, November 1978, 1979 and 1981). The rest of the activity was at the summit vents (mainly north-east and south-east craters) and at secondary vents lower down the volcano (mainly to the north), some of which were fed by lava tubes from the summit vents. Many of the eruptions were short, explosive, high effusion rate events such as those in the latter half of 1977. Other eruptive episodes involved continuous effusion for months at a time<sup>2</sup> such as those typifying the period September 1974 to June 1976. Our volume data (Table 1) come from various sources and are not corrected for vesicularity. The most accurate of these data are the result of theodolite surveying of the summit region<sup>3-5</sup>. Most lava flow volumes lower on the flanks have been estimated from their areas and average thicknesses. The accuracy of these less precise estimates is probably better than  $\pm 50\%$ .

The cumulative volume plot for January 1971-July 1981 (Fig. 1) has a linear trend which gives an output rate<sup>6</sup> of 0.7 m<sup>3</sup> s (0.67 m<sup>3</sup> s<sup>-1</sup>). For the period September 1974-June 1976 when effusion was almost continuous, though variable over short periods of time, the rate was indistinguishable (0.67 m<sup>3</sup> s<sup>-1</sup>) from the overall 1971-July 1981 rate. After a period of repose during 1972-73 following the 1971 flank eruption the cumulative volume curve has kept within the limits shown in Fig. 1, which represents a range of volume of about 25×106m3. There is a tendency for a change in style of eruption during the second half of this steady-state period (July 1977-July 1981), coupled with a slightly increased gradient of the curve, but this appears to be of secondary importance.

We interpret these features of Fig. 1 as follows. From 1971 to July 1981 magma has been entering and leaving Etna at a rate of 0.7 m<sup>3</sup> s<sup>-1</sup>. At times this steady state has been achieved exactly (within the precision of our data) as in 1975 and is equivalent to the behaviour of Kilauea in 1952, 1967-68 and 1969-71 (see ref. 7). At other times magma is either stored in the volcano before release or the magma arrives in discrete batches which

All volumes estimated to the nearest  $1 \times 10^6 \,\mathrm{m}^3$  except eruptions from 16 July 1977 to 7 January 1978 which are estimated to the nearest  $0.5 \times 10^6 \,\mathrm{m}^3$ .

results in a punctuated pattern of magma release. The maximum capacity of either of these processes (or a combination of them) is  $\sim 25 \times 10^6$  m<sup>3</sup>.

Recognition of this rate of magma discharge and the capacity of the episodic process(es) since 1974 (Fig. 1) allows us to suggest how Etna will behave in the immediate future. If the cumulative volume curve is to remain within the empirically defined limits Etna must erupt again before about May 1982. At that time up to  $25 \times 10^6$  m³ of magma could be expected, but an eruption volume of less than about  $17 \times 10^6$  m³ could be expected from an eruption in January 1982 (Fig. 1). These are not predictions of specific events but general forecasts of the timing and magnitude of future eruptions based on the behaviour of

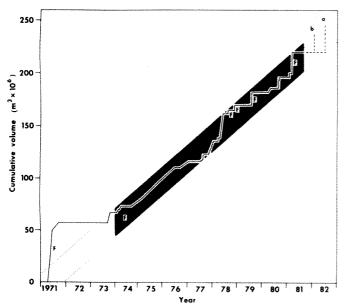

Fig. 1 Plot of the cumulative volume of magma erupted at Etna from 1971 to July 1981 listed in Table 1. F indicates eruptions involving flank vents. From January 1974 to July 1981 the cumulative volume curve has remained within the limits shown by the shaded area which corresponds to the average discharge rate calculated for the entire period 1971–July 1981  $(0.7 \text{ m}^3 \text{ s}^{-1})$ . If the volcano continues to behave in this way an eruption is expected to occur before approximately May  $1982 \pm 3$  months. An eruption at that time should not exceed a volume of about  $25 \pm 6 \times 10^6 \text{ m}^3$  (a). The maximum volume of an eruption in, say, January 1982 would be about  $17 \times 10^6 \text{ m}^3$  (b). If instead there is a larger volume eruption (as in 1971) a correspondingly long period of repose is expected to follow.

the volcano during the past seven years. The accuracy of such forecasts depends on the error involved in the volume estimates used in constructing the curve. Random errors in individual estimates (probably a few 10%) will tend to cancel in the cumulative volume curve and reduce the uncertainty in the limits of the shaded envelope of Fig. 1. Unknown systematic errors will affect the gradient of the curve. The above forecast depends in particular on the accuracy of the last eruption volume of the curve (March 1981), which is about  $\pm 10\%$  ( $20\pm 2\times 10^6\,\mathrm{m}^3$ ). Combined with an assumed uncertainty of the steady-state limits (shaded envelope) of  $\pm 20\%$  this produces an uncertainty of about  $\pm 3$  months and about  $\pm 6\times 10^6\,\mathrm{m}^3$  in the maximum repose period and volume of the next eruption.

The 1971 eruption does not fit the above pattern. From January 1966 until April 1971 summit effusion was very similar in style and magnitude to the 1975 activity8,9 and the rate of 0.7 m<sup>3</sup> s<sup>-1</sup> is also probably applicable to the 1966-71 period. If this is true then the 1971 eruption represents an event which involved an unusually large volume of magma and after which there was an unusually long repose period. The proposed steady-state rate of discharge from 1966 to 1981 of 0.7 m<sup>3</sup> s<sup>-1</sup> is equated with the rate of supply of magma from the lower crust and the 1971 eruption volume is part of that supply rather than originating in some additional reservoir or source region. The large volume implies that either a high-level reservoir was drained or that an unusually large batch of magma rose into the volcano, but that both were part of a steady supply system which required a subsequent period of recharge during 1972-73. If our assumption about the steady-state output rate from 1966 to April 1971 is incorrect then this weakens, but does not invalidate, the case for the 1971 eruption magma being part of the steady-state supply.

These conclusions reinforce the previously noted discrepancy between the modern discharge rate and the rate calculated from the flank eruptions of the past 200 yr (0.17 m³ s<sup>-1</sup>). We suggested that summit eruptions, whose volumes cannot be estimated for this period, might increase this latter value to 0.26 m³ s<sup>-1</sup>. However, the modern (1971–81) ratio of summit to flank magma volume of 56:44, if applied to the record of the past 200 yr, gives a combined summit and flank output rate of 0.39 m³s<sup>-1</sup>. There has been one historic period (1610–69) during which magma erupted at a rate (0.83 m³s<sup>-1</sup>) comparable with the 1971–81 rate¹. Between 1610 and 1669 there was no recorded summit effusion and the lavas of the very long-lasting flank eruptions were characterized by particularly large plagioclase phenocrysts 10. The large phenocrysts may imply longer residence times for magma at high levels than at present. Normal access to the summit vents may have been

blocked at this time and all the magma from depth may have found its way to the surface through flank vents.

The steady-state discharge of magma at Etna provides a framework within which some of the findings of recent research on the volcano can be correlated. The major element geochemistry of historical Etna lavas has shown little variation with time 10,11. A steady-state discharge rate must be an important factor in determining the chemical homogeneity of these hawaiite lavas. Small variations in residence time at high levels in the feeding fissures are probably capable of producing the observed limited variations in chemistry. Direct monitoring of SO<sub>2</sub> by correlation spectrometry in the plume of Etna during June 1975<sup>12</sup>, August 1977<sup>13</sup> and July 1978<sup>14</sup> has revealed a characteristic discharge rate for this species varying between 1.000 and 5.000 tonnes per day depending on the level of activity. A value within this range may represent the steady rate of release of SO<sub>2</sub> from a hawaiite magma flux of 0.7 m<sup>3</sup> s<sup>-1</sup> which is  $\sim 0.6-3$  wt.% of the mass of erupted magma (assuming the specific gravity of the magma is 2,650 kg m<sup>-3</sup>). However, this range is much higher than the sulphur contents of most sulphidesaturated basaltic liquids (<0.25 wt% S)<sup>15</sup>. If the spectrometer values are accurate then the Etna magmas are either exceptionally rich in sulphur or a larger volume of magma may be degassing than appears at the surface at the steady-state rate.

Various techniques for monitoring the surface deformation of Etna have been since 1971, including precise levelling, electronic distance measurements and several types of tiltmeters<sup>16-19</sup>. The most substantial deformations were measured from 1971 to 1974 during the period of recovery from the 1971 eruption<sup>16</sup>. Subsequent measured deformation has been relatively minor<sup>10</sup>. This suggests that there is no elastic reservoir system within the volcano that is sensitive to the discharge of up to  $25 \times 10^6$  m<sup>3</sup> of magma within the steady-state limits of Fig. 1.

We thank the many scientists whose observations on Etna over the past decade made this work possible. J.E.G. acknowledges financial support from NERC. G.W. is a visiting scientist at the Lunar and Planetary Institute which is operated by the Universities Space Research Association under contract NASW-3389 with NASA.

### Charnockite and granite formation and influx of CO<sub>2</sub> at Kabbaldurga

C. R. L. Friend

Department of Geology and Physical Sciences, Oxford Polytechnic, Oxford OX3 0BP, UK

The discovery, at Kabbaldurga quarry, Karnataka, south India 1-3, of patches of charnockite apparently in an arrested state of development has refocused attention on the mechanism of charnockite formation. In particular, the relative roles of CO2 and H<sub>2</sub>O during high grade metamorphism and charnockite development can be studied in such an area. During an influx of a CO2-rich volatile phase, H2O may be liberated as a result of the reduction in the state of hydration by the breakdown of hydrous minerals<sup>4</sup>. The P-T conditions in which this occurs are important because, with an increase in XH2O, conditions which may allow anatexis could be initiated in advance of such a CO2-rich phase. Indeed, Weaver<sup>5</sup> has suggested that the K-rich acid charnockites found at Pallavaram, Madras<sup>6</sup>, developed due to changes in volatile composition before the onset of charnockite conditions. The exposure at Kabbaldurga quarry is interpreted here as displaying evidence that such a process has taken place.

During recent field work in the Archaean (~2,700 Myr) gneiss terrain between Mysore and Bangalore, Karnataka, south India, the southern end of the Closepet Granite including the area of Kabbaldurga was examined. This granite is a substantial body with a linear extension northwards for some 200 km to just south of Bellary. The country rocks into which the granite has been emplaced are dominantly polyphase, grey Archaean gneisses-the Peninsular Gneiss complex. In this area the gneissic complex has been subjected to upper amphibolite and granulite facies conditions of metamorphism. The age of the Peninsular Gneiss complex precursors is not well known, but is at least 2,600 Myr (ref. 8), an age which reflects a metamorphic event. More recently, an Rb-Sr whole rock isochron age of 3,358 Myr has been obtained for part of the complex to the west of Bangalore9. Two homogeneous foliated granitoid masses, which also form a portion of the Peninsular Gneiss, at Chickmagalur and at Chitradurga, have given Rb-Sr ages around 3,080 Myr and 2,790 Myr respectively (S. Moorbath and P. N. Taylor, personal communication). These ages for components of the gneiss complex are consistent with that of 2,670 Myr (ref. 10), interpreted as a metamorphic age, which has been obtained from the charnockite and the gneisses at Kabbaldurga and 2,615 Myr for the general granulite facies event<sup>8</sup> of the area.

Among the studies of the Closepet Granite 7,11,12 the observations that most closely approach those made during the present investigation are those of Radhakrishna7, who differentiated the granite into four main varieties. Briefly, the present investigation suggests that the granite is itself a polyphase body and comprises several pinkish and/or greyish, coarse-grained, porphyrytic and non-porphyrytic granites (using the nomenclature of Streckeisen<sup>13</sup>) and various pegmatitic and aplitic phases. In some portions of the granite enclaves of the country rocks are present. In these areas it is evident that pink alkalifeldspar megacrysts present in the porphyrytic granites are not phenocrysts but are of replacive origin because the megacrysts are developed in and across the margins of some of the enclaves. Additionally in some areas, white alkali-feldspar megacrysts have been partially replaced by veins and patches of pink alkali-feldspar. This accords with the observations of Radhakrishna<sup>7</sup> and with the hypothesis<sup>11</sup> that metasomatism is involved in the production of the granite. There is frequently a distinct orientation of both types of megacrysts which is parallel to a variably developed foliation picked out by an alignment of biotite and to the northerly trend of the granite body. This feature suggests that the megacrysts have developed in response to late-stage K-rich fluids in a still active stress zone. This fluid could also be the source of the enrichment in Th, Rb and Pb as

London, 1980).

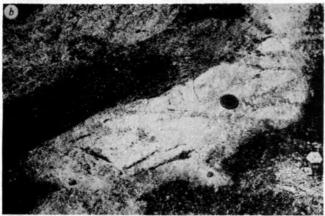

Fig. 1 The penecontemporaneous relationships of granite and charnockite. a, The nebulitic development of charnockite after the formation of granite. In the foreground and left-hand side grey migmatitic gneiss is cut by a sheet of granite. The right-hand contact of this sheet is gradational into the gneiss. Both of these lithologies have been overprinted by the nebulitic development of charnockite (see ref. 1) which forms the black areas. Running diagonally across the top right-hand corner of the photograph is an area of charnockite which occurs as anastamosing veins overprinting an area dominantly of granite. b, A thin sheet of granite ( $\sim$ 28 cm) without charnockite development, cutting and containing two schlieren of charnockite developed from grey gneiss. Above the granite sheet is a nebulitic contact between an area of charnockite and gneiss in which charnockite has begun to develop.

well as K reported from the northern portion of the granite body<sup>12</sup>. Additionally, the granite has a broad overall zonation<sup>7</sup> which is parallel to the northerly trend of the body.

On the southeastern side the rocks comprising the marginal contact zone of the granite are of particular interest. This contact zone consists of a series of intermixed, polyphase granitic sheets and veins (together with pegmatitic and aplitic rocks) enclosing and cutting enclaves of Peninsular Gneiss. In this area the Peninsular Gneiss consists of typical grey, banded gneisses with a few horizons of more basic material and some bodies of essentially unfoliated, more homogeneous gneiss. In the contact zone the enclaves display a range of textural and structural modification from relatively angular, unmodified gneisses into highly banded rocks passing into nebulitic and inhomogeneous, coarse-grained material which lacks a gneissic fabric and may be differentiated into neosome and palaeosome. Such material exhibits the structures and textures of migmatites 14,15. The transitions from these migmatitic rocks into more homogeneous granitic rocks are attributed to the process of anatexis and may be described as homogeneous and inhomogeneous diatexites (see ref. 15). From the field evidence in these areas I conclude that the origin of the Closepet Granite is due to partical melting in the Peninsular Gneisses. Crawford8 has determined the initial<sup>67</sup>Sr/<sup>86</sup>Sr ratio of the granite to be 0.705 ± 0.0014 which,

for  $\sim 2,400$  Myr, suggests a derivation by remobilization of pre-existing sialic material. The importance of this observation becomes apparent in the Kabbaldurga quarries where the relationships of the Closepet Granite to the formation of charnockitic rocks may be observed. The association of charnockitic rocks and migmatites is a feature which has long been known from other regions <sup>16</sup>. Kabbaldurga quarry is an area where data regarding this interesting relationship may be collected.

On close investigation the patchy development of charnockite can be seen to have occurred not only in the Peninsular Gneisses as has previously been described 1-3 but also in some of the rocks which form a part of the Closepet Granite. From field evidence the development of the charnockitic patches seems to be penecontemporaneous with the development of the granite. Veins and sheets of granite, without charnockitic assemblages, cut charnockitic patches in the gneisses yet are themselves cut by other granitic veins with charnockite development in them (Fig. 1). Note that the areas of gneiss in which chanockite has developed have not undergone partial melting3. However, in some of the grey, biotite gneisses around the patches of charnockite partial melting to produce granitic material has taken place. These rocks contain the structures and textures which closely resemble those found elesewhere along the southeastern marginal zone of the granite and which are interpreted as migmatitic and anatectic features. The onset of charnockite formation at Kabbaldurga is though to have taken place at between 3 and 5 kbar at 600-700 °C (ref. 3), (though this is a low estimate compared with the values suggested for the surrounding charnockite formation<sup>17</sup>, the mineral assemblages present do not allow a more accurate estimate to be made) and to have been initiated by an influx of a mantle-derived volatile phase rich in CO<sub>2</sub>. Such a mechanism has now been more widely applied to granulite facies rocks<sup>5,18</sup> to explain in particular the formation of hypersthene-bearing assemblages without a change in the existing P-T conditions. Whilst Janardhan et al. argue that a large rise of temperature is not required for the formation of charnockite at Kabbaldurga, the invading volatile phase may have brought a source of heat with it particularly as the volatile phase is considered to be mantle-derived3. Schuiling and Kreulen<sup>19</sup> attribute considerable potential to an invading volatile phase with respect to the release of heat and the initiation of anatexis. Although data enabling the application of their model calculations are not obtainable, any influx of heat will assist the breakdown of the hydrates present and the production of the observed migmatitic features. At Kabbaldurga, therefore, during such an advance of CO2, the hydrous minerals-in this case biotite and amphiblole-have broken down, without partial melting, to give hypersthene-bearing, non-foliated, charnockitic rocks. The H2O released by this breakdown would have immediately joined the volatile phase which would continue its upwards migration. Therefore, at any point with the continued breakdown of hydrous phases more H<sub>2</sub>O would be added to the volatile phase, eventually diluting the composition of the volatiles until such a time as the CO2 front advanced through that point. Although the invading volatile phase is K-rich3 there is no unequivocal evidence that this is a different volatile phase from that which gives rise to the growth of alkali feldspar megacrysts in the granite. I believe, however, that this latter phenomenon is a late-stage crystallization effect-in common with many other granites-and that the two volatile phases are not directly related.

The exposure at Kabbaldurga seems to have been in a rather special position, at the very front of the CO<sub>2</sub> advance, where the introduced volatile phases are subject to dilution by the released H<sub>2</sub>O. The H<sub>2</sub>O released by the breakdown of the hydrous phases has had serious consequences. In some areas of the grey gneisses not affected by charnockite formation, the granite solidus was reached and partial melting took place. Then, after the formation of the granite, the CO<sub>2</sub> front advanced into some of the areas where partial melt had accumulated and has formed K-rich charnockite. That there are areas of Closepet Granite in which charnockite has developed demonstrates that the two

events were penecontemporaneous. Weaver<sup>5</sup>, in discussing the generation of the K-rich charnockites at Pallavaram, considered that they represent an unusual component of an otherwise fairly typical Archaean grey gneiss-granulite terrain. He suggested that these K-rich rocks had developed due to a change of the fluid composition which allowed metasomatism and partial fusion to occur before the formation of charnockite by the advance of a CO<sub>2</sub> front. At the present level of erosion, the exposure is interpreted as having been well below the former position of the CO<sub>2</sub> front and all the rocks have been completley converted to charnockite.

At Kabbaldurga it appears that there is evidence not only of the arrested process of charnockite formation, but also of the process of crustal fusion induced by an accumulation of  $H_{2\mathrm{O}}$  in advance of an ascending CO2-rich volatile phase. Thus, this area of the Peninsular Gneiss complex and the Closepet Granite is fundamental to the understanding of the processes of both charnockite formation and granite formation deep in the crust.

A British Council ALIS award is acknowledged enabling the continuation of work begun ealier under a YSES fellowship. I also thank Professor C. Naganna and Dr B. Mahabaleswar, of Bangalore University, for financial assistance and for help in the field respectively and Drs B. P. Radhakrishna and A. S. Janardhan for discussions on the Closepet Granite and the Kabbaldurga area and M. Brown, V. R. McGregor and C. G. Topley for helpful comments.

# Limitations on the scale of mantle heterogeneities under oceanic ridges

#### Bernard Dupré, Bernard Lambret, Dominique Rousseau & Claude J. Allègre

Laboratoire de Géochimie et Cosmochimie, Institut de Physique du Globe et Département des Sciences de la Terre, Universités Paris VI et VII, 4 place Jussieu, 75230 Paris Cédex 5, France

The scale of mantle heterogeneities has been debated ever since the first observations of isotopic variations along mid-oceanic ridges<sup>1,2</sup>. Subsequent studies on lead and strontium isotopic variations along the Mid-Atlantic Ridge3-5 have shown that these isotopic compositions may vary with a major wavelength of  $\sim$ 100-1,000 km. The immediate question is that of the scale (if any?) at which one may consider a piece of suboceanic mantle under a ridge to be homogeneous. We have studied two segments of oceanic ridges at the scale of a few kilometres. One of these portions of oceanic ridge, the CYAMEX zone in East Pacific Rise is typical, with a strongly 'depleted' chemistry. The other one, with an 'intermediate' chemistry, is the FAMOUS zone of the Mid-Atlantic Ridge. Our results show isotopic homogeneity for both zones even though small Pb variations persist on a small scale.

The general geology of the FAMOUS area has been described elsewhere<sup>6,7</sup>. In the central valley of this slow spreading ridge (2 cm yr<sup>-1</sup>), we can distinguish two types of structures, real volcanoes such as Mount Venus, and lava flows, probably of fissural type. Several samples were collected from each structure. Figure 1 shows the location of the 16 samples analysed; the area covered was a few square kilometres.

The CYAMEX zone is located on the East Pacific Rise at a latitude close to 21° N. The mean spreading rate of this ridge is  $\sim$ 6 cm yr<sup>-1</sup>. In contrast with the FAMOUS area, the CYAMEX zone presents no clearly defined central valley. Detailed tectonic8, petrographic9 and geochemical10 studies are available. The area is characterized by more abundant fluid lavas than in FAMOUS, some in the form of the peculiar 'lava lakes'8. Hydrothermal circulation has been discovered in this area where the massive sulphide or manganese deposits originate11

Measurements and normalization of lead and strontium isotope ratios were completed using techniques described in refs 12, 13: the results are presented in Table 1.

In the FAMOUS area the strontium isotope values for whole rocks vary from 0.70287 to 0.70347. Such variations may a priori be ascribed to several causes. After leaching, using O'Nions and Pankhurst's<sup>14</sup> differential solution technique, samples yield values which are very close to 0.70287, in agreement with analyses by White 15,16 and O'Nions and Pankhurst14 for neighbouring areas. Therefore, the variation mentioned above can be attributed to seawater alteration and within the experimental error, the isotopic composition of Sr seems to be very constant.

The lead isotope values are rather uniform and close to ean values of  $^{206}\text{Pb}/^{204}\text{Pb} = 18.7$ ,  $^{207}\text{Pb}/^{204}\text{Pb} = 15.53$ ,  $^{208}\text{Pb}/^{204}\text{Pb} = 38.20$  with a maximum variation of 0.2 for <sup>206</sup>Pb/<sup>204</sup>Pb. Such a variation is quite small, compared with those observed for the North Atlantic as a whole<sup>17</sup> (1.9 for <sup>206</sup>Pb/<sup>204</sup>Pb). No marked difference can be observed between different types of lavas from volcanoes and fissural lava flows.

In the CYAMEX area the strontium isotope values on whole rocks and glasses are uniform and average about 0.7025 which is

We have divided the samples from the FAMOUS zone into two groups: IG, international ground; FZ fracture zone. The total blank for  $\sim$ 1 g of sample has been maintained below 1 ng for Pb and below 200 pg for Sr. WR, whole rock.

typical of the depleted mid-oceanic ridge basalts (MORB). The lead isotope values are also rather uniform but yield a less radiogenic character than for FAMOUS:  $^{206}\text{Pb}/^{204}\text{Pb} = 18.35$ ,  $^{207}\text{Pb}/^{204}\text{Pb} = 15.48$ ,  $^{208}\text{Pb}/^{204}\text{Pb} = 37.85$ .

The (Sr, Pb) or (Pb, Pb, Pb) isotope correlation diagrams (Fig. 2) show that both CYAMEX and FAMOUS data plot on the main trend defined for MORB<sup>17-19</sup>. Therefore, both zones have quite 'normal' chemical characteristics of an oceanic ridge. The uniformity of their isotopic compositions which contrasts with the variations observed in the North Atlantic<sup>16,17</sup> and with the local heterogeneities observed in peridotite xenoliths and 'high temperature' peridotites<sup>20,21</sup> has important implications. In this case, the source of basalts at the scale of 10 km is statistically homogeneous, the formation of a basaltic liquid compensates for any local minor heterogeneity in the mantle source.

Although the Pb values are roughly homogeneous, some small variations in the Pb isotope ratios remain and cannot be ascribed to secondary processes such as seawater alteration. These variations are about one-tenth of the global variation for the North Atlantic (when using the Sr-Pb correlation diagram, we may estimate the corresponding variation for the values obtained close to 0.0001, which for 87Sr/86Sr is virtually the same as those expected from the analytical error). Thus, the small variations in Pb isotopic ratios are not inconsistent with the uniformity of the Sr isotope ratios. Improvements in measuring the Sr isotopic ratio are necessary before we can study Pb-Sr correlation on such a small scale. However, on this scale these Pb isotope variations are not correlated with variations in ratios of incompatible elements like Hf/Th, Ta/Th, La/Th or La/Sm. Therefore, such small heterogeneity is not an argument against the trace element discussion made by Langmuir et al.<sup>22</sup> who

**Fig. 2** Results for CYAMEX and FAMOUS areas: a,  $(^{87}\text{Sr}/^{86}\text{Sr})$  vs  $(^{206}\text{Pb}/^{204}\text{Pb})$ ; b,  $(^{208}\text{Pb}/^{204}\text{Pb})$  vs  $(^{206}\text{Pb}/^{204}\text{Pb})$ ); c,  $(^{207}\text{Pb}/^{204}\text{Pb})$  vs  $(^{206}\text{Pb}/^{204}\text{Pb})$ .

reject the equilibrium partial melting model and propose a new model for partial melting called dynamic-melting.

We now compare the homogeneity observed on a small scale

(10 km) with that observed on a larger scale (100-1,000 km). Results from the North Atlantic<sup>3,5,17</sup>, and those on the oceanic crust of the Indian Ocean<sup>23</sup> indicate that the cause of isotopic variations obtained along the Atlantic Ridge is linked to mixing between the lower and upper mantle by injection of blobs (or hot spots). Our results show that, on a small scale, the mixing does not generate large isotopic heterogeneities but this conclusion should be evaluated in the light of the type of models discussed in ref. 18. Note that the Pb heterogeneity is larger in the case of FAMOUS than for CYAMEX. Considering that FAMOUS is on a ridge with some blobs mixing while CYAMEX is on a quite 'normal' ridge, such a difference is probably significant. With improvement of the accuracy, it will be quite interesting to study the small variations of Sr isotope ratios in these areas to decipher more precisely the processes of blob mixing and basalt genesis.

### Palaeooceanographic significance of bottom-current fluctuations in the Southern Ocean

### Michael T. Ledbetter

Department of Geology, University of Georgia, Athens, Georgia 30602, USA

Hiatuses in the sedimentary record of the Southern Ocean are usually attributed to erosion by high-velocity bottom 3. To test for palaeoclimatic mechanisms which currents 1-3 intensified bottom circulation, however, the timing of increases in bottom-current velocity must be known. As the sedimentary record of the period of initial erosion is lost within the hiatus, the timing of increased velocity must be determined in cores which are adjacent to the axis of highest velocity4.5. In those cores the accumulation rates are reduced due to the current but a record of the period of initiation of scour is preserved as a zone of particle-size winnowing of the fine-fraction3-4. The timing of major episodes of bottom-current intensification in the South Australian Basin for the past 4.5 Myr are reported here for the first time and may be used to examine the role of palaeoclimatic fluctuations on bottom-current intensity.

A series of piston cores across the axis of a high-velocity current (near a modern contour current<sup>6</sup>) which has produced hiatuses in the sedimentary record<sup>2</sup> in the South Australian Basin (Fig. 1) are used to demonstrate a method of dating erosional pulses of bottom water. These disconformities are of varying length depending on width, intensity and duration of the high-velocity bottom current responsible for scouring the sea floor. Two of the cores (E48-5 and E45-86) near the axis of flow during an expansion of the contour current have a hiatus which extends from the Miocene to latest Pleistocene while hiatuses in two adjacent cores (E49-53 and E50-2) are shorter (Fig. 2). One core (E45-21) in the area has not recorded a hiatus due to its position at the margin of the bottom water even at its greatest extent during the past 3 Myr. Because three of the cores were the site of deposition during the time span lost due to erosion in the axial-cores (Fig. 2), the particle-size distribution in those cores may be examined for evidence of winnowing which is associated with the erosion.

The mean particle-size of the non-carbonate silt fraction  $(4-62 \mu m, 8-4 \phi)$  was analysed using an electronic particle counter7 (Elzone, Particle Data). The carbonate fraction was not analysed as variations in carbonate grain-size may be affected by dissolution of carbonate rather than bottom-current velocity8. The silt fraction was analysed because the fine fraction is more sensitive to the magnitude of bottom-current velocity observed in the deep sea<sup>9,10</sup>. As the cores studied are too far from Antarctica to have a significant ice-rafted debris component the grain size of the non-carbonate silt-sized component chiefly reflects bottom-current transport. The mean silt particle size in three cores was plotted against age (Fig. 3) determined from magnetostratigraphy<sup>1,3</sup>. The mean value of the data in each core is used as an arbitrary reference level to separate periods of relatively high and low inferred bottom-water velocity (Fig. 3).

The period of erosion (or non-deposition) in core E50-2 is characterized by coarse particle sizes in the two cores (E49-53 and E45-21) marginal to the high-velocity zone (Fig. 2). Therefore, the erosional event(s) in E50-2 is 'felt' in the more distant cores by winnowing of the fine fraction. When the period of erosion or non-deposition ceased in core E50-2 the mean particle size deposited was still coarse under the waning current. In the adjacent cores, the mean particle size decreased at the same time that sedimentation resumed above the disconformity. Therefore, the marginal cores have recorded the cessation of high-velocity bottom current at ~2.6 Myr.

The initiation of the high-velocity episode may be dated at the beginning of the winnowing of particles in the marginal cores. While sediment is missing for the period 5.5-4.6 Myr, it is possible to examine the record of bottom-current velocity for the past 4.5 Myr and for a short period at ~5.5-5.6 Myr (Fig. 3). The first episode of high-velocity is marked by a coarsening of the mean particle size at ~4.3 Myr which persisted until ~3.8 Myr. Several shorter pulses with lower magnitude followed the initial coarsening of mean particle size and may record periods of current intensification which either eroded or inhibited deposition at the site of core E50-2. The episodic nature of the inferred bottom-water velocity fluctuations imply that sediment was deposited and subsequently eroded in the scour zone so that the hiatus is a result of multiple high-velocity events.

Unfortunately, the bottom-current velocity record of the lower Gilbert Chron cannot be examined due to the lack of recovery of sediment of that age in the South Australian Basin<sup>2</sup>. If, however, the initial increase in bottom-current velocity occurred at 3.8-4.3 Myr, then ~1 Myr of sediments were eroded at the site of core E50-2 (Fig. 3). Based on average sedimentation rates after the disconformity of 0.35 cm kyrcores E50-2 and E45-21, the episodes of increased velocity eroded ~3.5 m of sediment deposited before 4.3 Myr and 5 m was eroded and/or not deposited from 4.3 to 2.6 Myr. The total erosional effect of the bottom currents in this area, therefore, is nearly 10 m of sediment. Areas of more intense erosion have occurred in the southeastern Indian Ocean as much older sediment is exposed by other disconformities1.2 which must have been nearer the axis of flow.

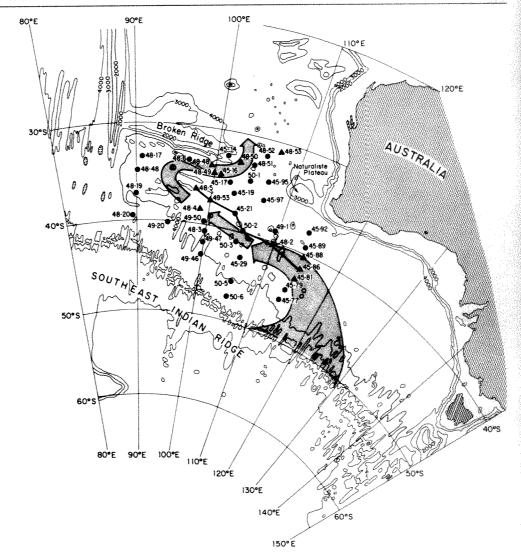

Fig. 1 Map of South Australian Basin showing major physiographic features, bathymetry and Eltanin core locations<sup>3</sup>. Arrows indicate an inferred bottom-water path based on the presence of cores with hiatuses (△)<sup>2</sup>. ♠, Cores without hiatuses<sup>2</sup>. The pathway is near a modern contour-current identified from benthic foraminiferal assemblages<sup>6</sup>. Profile refers to cores in Fig. 2.

A second unconformity in the area is recorded in core E49-53 (ref. 2). The base of the hiatus is at  $\sim 1.35$  Myr (Fig. 2) and the overlying sediment is known to be < 0.72 Myr because it is all within the normal polarity Brunhes Chron (Fig. 2). Much of the period represented by the hiatus in E49-53 is characterized by high inferred bottom-current velocity in cores E45-21 and E50-2 (Fig. 3). An episode of high velocity is recorded from 1.4 to 0.75 Myr. As the high velocity event began near the time of the base of the hiatus, there may have been no erosion but just winnowing and non-deposition of sediment. Sediment above the disconformity may fall anywhere within the period of low-velocity which encompasses the Brunhes Chron and no attempt was made to determine palaeovelocity fluctuations as no age could be assigned.

The history of AABW velocity may be examined in detail for the first time. The period of increased velocity 3.8-4.3 Myr in the South Australian Basin corresponds to an increased hiatus frequency throughout the south-east Indian Ocean (Fig. 4). The increase in bottom-water velocity in the late Gilbert Chron occurred at the same time as a major cooling in the Antarctic region 12-14. Fluctuations observed in the temperature of the sub-Antarctic and Antarctic region 12 closely match the pulses in bottom-water velocity with cold climatic conditions corresponding to increased velocity. When climatic conditions in the sub-Antarctic and Antarctic warmed in the Gauss Chron 13, the bottom-current velocity waned. The increased benthic circulation with Antarctic region refrigeration occurred due to either increased thermohaline circulation or increased wind stress on the Antarctic circumpolar current; either mechanism could result from steepened Equator to poleward temperature gradients. The Northern Hemisphere refrigeration which resul-

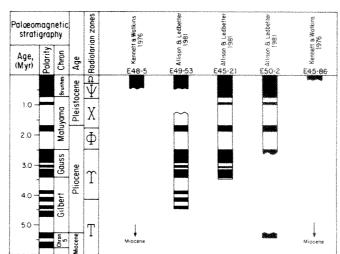

Fig. 2 Magnetostratigraphy of five cores on a profile across the path of a bottom-current in the Australian Basin (see Fig. 1). The disconformities in these cores may be traced into cores E49-53, E45-21 and E50-2 where winnowing of the grain-size population may be used to date the initiation of high velocity events which created a scour zone.

ted in the ice ages, however, occurred at 3.2 Myr (ref. 15) at a time when Antarctic bottom-current circulation waned in the southeastern Indian Ocean (Figs 3, 4), the South Atlantic Ocean<sup>4</sup> and South Pacific Ocean<sup>16</sup>.

The decreased Antarctic-source bottom circulation at the time of the initiation of the Quaternary glaciations may have

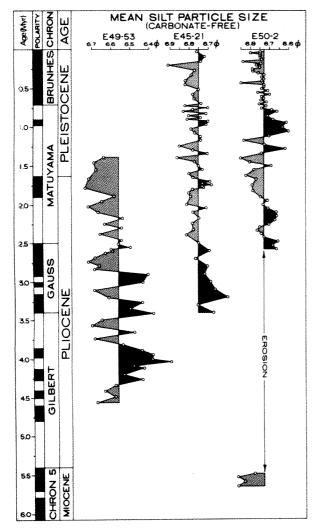

Fig. 3 The mean particle size of the carbonate-free silt fraction in cores E49-53, E45-21 and E50-2 is plotted against age. Blackened areas represent highest relative inferred bottom-water velocity. The disconformity in E50-2 is synchronous with a winnowing zone in E49-53 and E45-21 which is characterized by coarser particle sizes. Highest inferred bottom-water velocity occurred in the late Gilbert and Gauss Chrons. The initiation of winnowing in core E49-53 at 4.3 Myr marks the beginning of the erosion in core

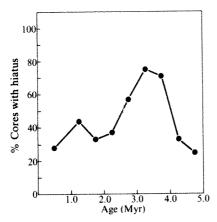

Fig. 4 The percentage of all cores >4440 m in the south-east Indian Ocean 1.2.18 is  $\ge 2.5-4$  Myr BP. The increase in hiatus frequency at ~4 Myr is nearly synchronous with an inferred increase in bottom-current velocity in core E49-53 and the decrease at ~2.5 Myr is nearly synchronous with a decrease in bottom-current velocity inferred in three cores (see Fig. 3).

important palaeooceanographic implications. In the modern ocean, North Atlantic deep water (NADW) provides the salinity component of AABW which increases the density of the cold current to the point where it is the densest water-mass in the ocean. If the production of NADW is affected by the ice ages, then a direct effect may occur in AABW production rates. Two effects may be postulated, however. Cooler Northern Hemisphere climates might increase NADW production through increased sea-ice production in the Norwegian Sea. The cooler climates, however, may result in long periods of thickened sea-ice which halt NADW production by limiting the reservoir for cold saline water within the Norwegian Sea. The latter method has been postulated for Pleistocene glaciations<sup>17</sup> and may be responsible for the decrease of AABW at the onset of the ice ages.

### C<sub>27</sub>-C<sub>29</sub> ring A monoaromatic steroids in Cretaceous black shales

#### G. Hussler, B. Chappe, P. Wehrung & P. Albrecht\*

Laboratoire de Chimie Organique des Substances Naturelles, associé au CNRS, Institut de Chimie, Université Louis Pasteur, 1 rue Blaise Pascal, 67008 Strasbourg, France

The structural elucidation of aromatic steroid hydrocarbons, which are widespread constituents of sediments and petroleums, has been attempted<sup>1</sup>; several series of triaromatic steroids have been identified<sup>2,3</sup> and a structural hypothesis for the major series of the ubiquitous ring C monoaromatic steroids has been proposed<sup>2,4</sup>. Although many of these monoaromatic compounds are already present in ancient shales of a low degree of maturity, the stage at which they form and the mechanism of their aromatization are still unclear. Early aromatization of ring A of steroids has been suspected<sup>5.6</sup>, but never confirmed. Here we report the elucidation of the structures of two series of ring A monoaromatic steroids, 1 and 2, which occur in immature Cretaceous black shales from the Southern and Eastern North Atlantic, collected during the Deep Sea Drilling Project (DSDP). Compounds 1 and 2 were identified as major constituents of the aromatic fractions of these samples by comparison with authentic standards.

Steroid derivatives have been widely used as geochemical markers to study chemical transformations at various stages of diagenesis or maturation in the subsurface. There is good evidence for early alterations of the steroid skeleton in recent or immature ancient sediments: microbial reduction of the  $\Delta^5$ double bond, dehydration of stanols leading to  $\Delta^2$ -sterenes and the subsequent formation of steranes or isomerization of

<sup>\*</sup> To whom correspondence should be addressed

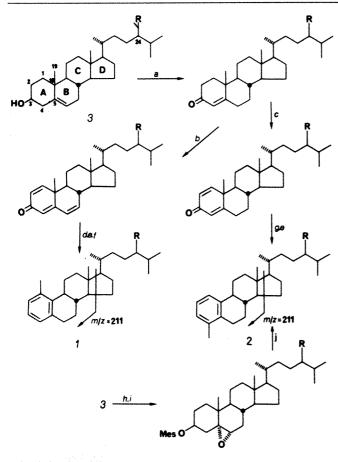

Fig. 1 Scheme of synthesis of ring A monoaromatic steroids, after refs 15-17. a, Cyclohexanone, Al(O-iPr)<sub>3</sub>; b, chloranil, pentanol; c, DDQ, dioxane; d, iPr-OH, Al(O-iPr)<sub>3</sub>; e, H<sup>+</sup>; f, H<sub>2</sub>, Pd/C; g, LiAlH<sub>4</sub>; h, CH<sub>3</sub>SO<sub>2</sub>Cl; i, m-ClC<sub>6</sub>H<sub>4</sub>CO<sub>3</sub>H; j, CH<sub>3</sub>CO<sub>2</sub>H, HBr 48%.

sterenes<sup>7-11</sup>. However, the aromatization reactions of this class of molecules, which is widespread in living organisms, in particular in phytoplankton, have been little studied<sup>1</sup>, despite the fact that the distributions of aromatic steroids are being increasingly used, as a fingerprint, in problems of maturation of geological organic matter<sup>3</sup>, as well as for correlating crude oils and their source rocks<sup>12</sup>.

The black shale samples (10-20 g) were obtained from DSDP Legs 40 (sites 364 and 365) and 41 (site 367) in the Angola and Cape Verde basins. These shales have been deposited in anoxic environments; their organic carbon content is high, ranging from 16 to 5% (refs 13, 14). The samples were extracted with chloroform and total extracts were separated by column and TLC over silica gel. The content of total aromatic hydrocarbons ranged between 17 and 5% of the extract. The mono+ diaromatic hydrocarbons were further purified by HPLC (SiO<sub>2</sub>, 10 µm; heptane) as described previously<sup>2</sup> and analysed by computerized gas chromatography-mass spectrometry (GC-MS; LKB 9000 S). Steroid hydrocarbons bearing on aromatic A or B ring display a major fragmentation at m/z = 211, which can be used for the study of their distribution by mass fragmentography of this specific ion (Fig. 1). The mass fragmentograms of the molecular ions at m/z = 366, 380 and 394 show a very similar distribution in which at least four major series are apparent (Fig. 2).

Compounds 1 (R = H) and 2 (R = H; R =  $C_2H_5$ ) were prepared from cholest-5-en-3 $\beta$ -ol (cholesterol; 3, R = H) and 24(R) -ethylcholest-5-en-3 $\beta$ -ol (sitosterol; 3, R =  $C_2H_5$ ) as a starting material (Fig. 1)<sup>15-17</sup>. Their structural data agree with those of the literature<sup>15,16,18</sup> and were confirmed by proton magnetic resonance and mass spectrometry.

1 R = H 1-methyl-19-nor-cholesta-1,3,5(10)-triene NMR (250 MHz; CDCl<sub>3</sub>;  $\delta$  p.p.m. JHz): 0.75 (3H,s); 0.87 (6H,d,J = 6.4); 0.93 (3H,d,J = 6.4); 2.29 (3H,s);6.69-6.85 (3H,m). MS (70 eV): m/z = 366 (M<sup>+</sup>, 95%); 351 (18%); 253 (M<sup>+</sup> - C<sub>8</sub>H<sub>17</sub>; 4%); 226 (17%); 211 (100%); 197 (12%); 183 (12%); 170 (34%); 158 (42%); 157 (64%); 143 (35%); 131 (55%).

2 R = H 4-Methyl-19-nor-cholesta-1,3,5(10)-triene NMR (250 MHz; CDCl<sub>3</sub>;  $\delta$  p.p.m., JHz): 0.71 (3H,s); 0.88 (6H,d,J = 6.4) 0.95 (3H,d,J = 6.4); 2.17 (3H,s); 6.83-7.04 (3H,m). MS (70 eV): m/z = 366 (M<sup>+</sup>, 85%); 351 (2.5%); 253 (M<sup>+</sup> - C<sub>8</sub>H<sub>17</sub>; 2%); 226 (15%); 211 (100%); 197 (8%); 183 (6%); 170 (10%); 158 (65%); 157 (32%); 143 (20%); 131 (36%).

R = C<sub>2</sub>H<sub>5</sub> 4-Methyl-24-ethyl-19-nor-cholesta-1,3,5(10)-triene NMR (250 MHz; CDCl<sub>3</sub>; δ p.p.m., JHz); 0.71 (3H,s); 0.83 (3H,d,J = 6.8), 0.85(3H,d,J = 6.8), 0.86(3H,t,J = 6.8); 0.95(3H,d,J = 6.4); 2.16 (3H,s); 6.83-7.04 (3H,m). MS (70 eV): m/z = 394 (M<sup>+</sup>, 85%); 379 (2.5%); 253 (M<sup>+</sup>-C<sub>10</sub>H<sub>21</sub>; 5%); 226 (13%); 211 (100%); 197 (8%); 183 (6%); 170 (10%); 158 (66%); 157 (32%); 143 (16%); 131 (34%).

These compounds were identified with those occurring in the geological samples by comparison of the mass spectra and coelution in single ion mass fragmentography GC-MS on two glass capillary columns (SE 30; SP 2250, Supelco, 25 m× 0.25 mm). Compounds 1 (R = CH<sub>3</sub>; C<sub>2</sub>H<sub>5</sub>) and 2 (R = CH<sub>3</sub>) were tentatively identified on the basis of their mass spectra and retention times.

The immature character of these Cretaceous black shales  $^{13.14}$  is confirmed by the presence of the less stable  $\beta\beta$ -hopane series as major constituents of the alkane and acid fractions, as well as an important fraction of unsaturated hydrocarbons in which monosterenes and hopenes are largely predominant (B.C. and P.A., unpublished data). The identification of monoaromatic steroids 1 and 2 shows that the aromatization of ring A of the precursor sterols begins at a very early stage of diagenesis. These results also demonstrate a novel pathway of aromatization of sterols in the subsurface, starting in ring A rather than in ring C

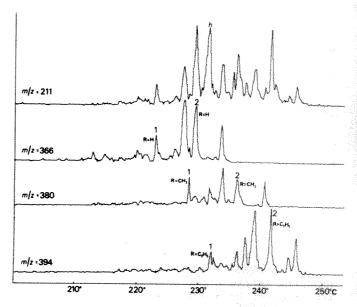

Fig. 2 Mass fragmentograms of ions 211, 366, 380 and 394 showing the distribution of ring A monoaromatic steroid hydrocarbons in a Cretaceous black shale from the DSDP (Leg 40, site 364). Numbers refer to structures in Fig. 1. h, Monoaromatic C<sub>27</sub> hopanoid. Conditions: SP 2250, 25 m × 0.25 mm, 0.08 μm, 140–250 °C, 2 °C min<sup>-1</sup>. Computerized GC-MS, LKB 9000 S.

as previously described<sup>1,2,4</sup>. Note that only traces of ring C monoaromatic steroids have been detected in our samples which mostly correspond to confined reducing environments. Ring C aromatization obviously needs further isomerization of the precursor sterenes, which seem to be favoured by a more open and oxidizing environment (B.C. and P.A. unpublished data).

The geochemical aromatization reaction proceeds with a shift of the C-19 methyl group of the precursor sterols from position 10 to position 1 or a preferred rearrangement to position 4, both reaction pathways being similar to the action of acids on various unsaturated steroid derivatives in the laboratory 15,19. Loss of the angular methyl group seems to be negligible in our case, as indicated by a weak m/z = 197 mass fragmentogram. The aromatization process of ring A of sterols could well be due, in its final steps, to an acid catalysis of minerals, clays in particular, acting in the sediments at an early stage of diagenesis. The cholestatrienes leading to the aromatic hydrocarbons 1 and 2 could have been formed by microbial and chemical transformations of the parent sterols<sup>8,20</sup>. As ring A monoaromatic steroids have not yet been observed in significant amounts in more mature sediments, they are probably intermediates of degradation of steroids restricted to early diagenesis, leading later to triaromatic steroids.

Work is in progress on the identification of the other series of monoaromatic or triunsaturated steroid hydrocarbons occurring in geological samples.

We thank the Institut Français du Pétrole for financial support and supply of samples, also Professor G. Ourisson for his interest and helpful discussions.

### $N\alpha$ -acetylation is linked to $\alpha$ -MSH release from pars intermedia of the amphibian pituitary gland

Gerard J. M. Martens, Bruce G. Jenks & A. P. van Overbeeke

Department of Zoology, Faculty of Science, Catholic University, Toernooiveld, 6525 ED Nijmegen, The Netherlands

Most amphibians can adapt their colour to that of their background by a mechanism which is controlled by melanophore stimulating hormone (MSH), a product of the pars intermedia of the pituitary gland1. Although the melanotropic peptides of amphibians have never been sequenced, immunological evidence indicates that at least some of them are structurally related to  $\alpha$ -MSH<sup>2-4</sup>. In our studies of the biosynthesis and structure of melanotropic peptides in the pars intermedia of Xenopus laevis, we have found evidence, reported here, for des-N $\alpha$ -acetyl- $\alpha$ -MSH as the immediate precursor of  $\alpha$ -MSH, with the acetylation taking place just before or during release from the pituitary.

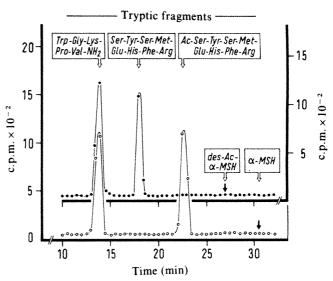

Fig. 1 Tryptic peptide mapping by HPLC of newly synthesized des- $N\alpha$ acetyl- $\alpha$ -MSH ( $\odot$ ) and  $\alpha$ -MSH ( $\odot$ ). Neurointermediate lobes of black-adapted X. laevis were incubated for 4.5 h at 22 °C in 50  $\mu$ l incubation medium (for composition see ref. 5) containing 20 µCi each of <sup>3</sup>H-lysine, <sup>3</sup>H-tyrosine, <sup>3</sup>H-phenylalanine and <sup>3</sup>H-tryptophan (specific activities 90, 50, 80 and 26 Ci mmol<sup>-1</sup>, respectively; Amersham). Lobes were extracted with 500 µl 0.1 M HCl, the extract was analysed with HPLC, and the newly synthesized product co-eluting with synthetic des- $N\alpha$ -acetyl- $\alpha$ -MSH was isolated from the lobes. To the incubation medium 500  $\mu$ l 0.1 M HCl were added, the acidified medium was analysed with HPLC and the newly synthesized product co-eluting with synthetic α-MSH was isolated from the incubation medium. Tryptic digestion of the isolated peptides (to which 20  $\mu$ g bovine serum albumin were added) was performed at 37 °C for 2 h with 10  $\mu$ g trypsin (DPCC-treated; Sigma) in 10  $\mu$ l 55 mM HEPES buffer (pH 8.0); the digest was analysed with HPLC. Digestion of the radioactive tryptic fragments to free amino acids revealed that the 14-min fragments contained radioactive tryptophan and lysine, and both the 18- and 22.5-min fragments contained radioactive tyrosine and phenylalanine. Black arrows indicate the elution positions of the undigested radioactive peptides. For comparison, 50 µg synthetic des- $N\alpha$ -acetyl- $\alpha$ -MSH (a gift from Dr G. I. Tesser, Department of Organic Chemistry, Nijmegen) and 50 µg α-MSH (Peninsula) were digested with 10 µg trypsin in the same conditions as described for digestion of the radioactive peptides, except no bovine serum albumin was added. The tryptic fragments of the synthetic peptides (shown in upper boxes) were detected with a post-column derivatization system, using o-phthaldialdehyde (Sigma) as a fluorogenic reagent, and they were further identified with specific staining techniques for the amino acids histidine and tryptophan according to ref. 20. The elution positions of the undigested synthetic peptides are also indicated (lower boxes). HPLC separation was on Spherisorb 10 ODS (Chrompack, 250×4.6 mm i.d.) using a stepwise gradient with a flow rate of 2 ml min<sup>-1</sup>, and 0.5-min fractions were collected. The gradient was established with 0.5 M formic acid, 0.14 M pyridine (pH 3.0) as the primary solvent and 1-propanol as the secondary solvent

We have previously shown by in vitro pulse-chase techniques coupled to HPLC analysis that the biosynthesis of peptides in the pars intermedia of X. laevis begins by the production of a large protein which is subsequently processed to a number of peptides5, three of which possess melanotropic activity. One of them has since been shown to co-migrate with synthetic des- $N\alpha$ acetyl- $\alpha$ -MSH on acid-urea gels and to have identical retention times to the synthetic peptide during HPLC analysis with several different elution gradients (unpublished observations). Tryptic digestion of this newly synthesized peptide yielded two fragments (Fig. 1) with elution times identical to those of the two fragments obtained from the tryptic digest of synthetic des- $N\alpha$ acetyl- $\alpha$ -MSH. Moreover, the radioactive amino acid content of the tryptic fragments was in agreement with that expected on the basis of the amino acid content of the comparable fragments of the synthetic peptide. Therefore, this newly synthesized melanotropic product is des- $N\alpha$ -acetyl- $\alpha$ -MSH. Another melanotropic peptide co-eluted from the HPLC column with synthetic  $\alpha$ -MSH and co-migrated with this peptide during acid-urea gel electrophoresis. The elution times of the two radioactive tryptic fragments of this newly synthesized product (Fig. 1) corresponded exactly with those of the two tryptic fragments of synthetic  $\alpha$ -MSH. Furthermore, the radioactive amino acid content of each tryptic fragment of this product was in full agreement with its identity as  $\alpha$ -MSH. The designation of the two newly synthesized products is supported by the observation that the only structural difference between them is located on the N-terminus.

Pulse-chase analysis of the biosynthesis of des- $N\alpha$ -acetylα-MSH and α-MSH revealed a likely precursor-product relationship for these peptides. During the first 2 h des- $N\alpha$ acetyl- $\alpha$ -MSH accumulated rapidly, then gradually decreased. α-MSH was barely demonstrable in the first 2 h and gradually increased thereafter, concomitant with the decrease of des-Naacetyl- $\alpha$ -MSH (Fig. 2). A further observation was that des- $N\alpha$ acetyl-\alpha-MSH was almost completely restricted to the tissue while  $\alpha$ -MSH was exclusively found in the medium. Additional experiments were performed to establish that the absence of des-Nα-acetyl-α-MSH in the medium was not the consequence of extracellular acetylation or rapid degradation of this peptide. Isolated radioactive des-Na-acetyl-a-MSH, incubated with neurointermediate lobes, remained in the non-acetylated form and was stable for at least 8 h. Moreover, superfusion of neurointermediate lobes, whereby any possible modification or proteolysis of secreted peptides was prevented by collecting the perfusate in solutions containing acid or enzyme inhibitors, demonstrated that over 95% of the newly synthesized MSH released was in the acetylated form.

In amphibians, the physiological factor inhibiting MSH release is thought to be dopamine<sup>6,7</sup>. In Xenopus, this cate-cholamine inhibits the in vitro release of all newly synthesized peptides<sup>8–10</sup>. To investigate the effects of inhibition of release on the acetylation process we conducted pulse-chase experiments with dopamine present during the chase. In the control experiment, ~40% of the newly synthesized MSH was in the  $\alpha$ -MSH form and, as expected, this acetylated product was found exclusively in the medium (Fig. 3a). The des-N $\alpha$ -acetyl- $\alpha$ -MSH was found almost exclusively in the tissue. In the dopamine-treated group, release of newly synthesized peptides was completely inhibited and all MSH in the tissue was des-N $\alpha$ -acetyl- $\alpha$ -MSH (Fig. 3b). Thus, inhibition of release was accompanied by inhibition of acetylation.

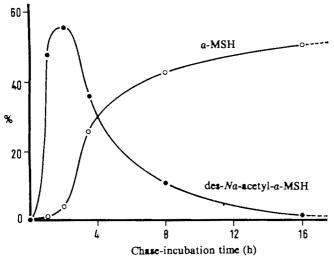

Fig. 2 Levels of newly synthesized des- $N\alpha$ -acetyl- $\alpha$ -MSH and  $\alpha$ -MSH as a function of chase-incubation time. *Xenopus* neurointermediate lobes were presentated for 1 h before a 30-min pulse incubation in <sup>3</sup>H-tryptophan, followed by chase incubations in normal incubation medium for 1, 2, 3 5, 8 or 16 h After the pulse-chase incubations, lobe extracts and incubation media were analysed with HPLC. With the gradient used, newly synthesized des- $N\alpha$ -acetyl- $\alpha$ -MSH and  $\alpha$ -MSH eluted at 22.5 mm and 28 mm, respectively. To quantify the relative amounts of these peptides, the chromatographic profile between 20 and 30 min elution time was used. For each chase group, the total level of radioactivity (lobe plus medium) was determined by adding the c p m. values of the HPLC fractions. The radioactivity of each HPLC fraction was then expressed as a percentage of this total level. In the figure, the percentages represent the sum of the percentage found in the lobe and that in the medium for des- $N\alpha$ -acetyl- $\alpha$ -MSH ( $\Theta$ ) or  $\alpha$ -MSH (O) at each chase-incubation time.

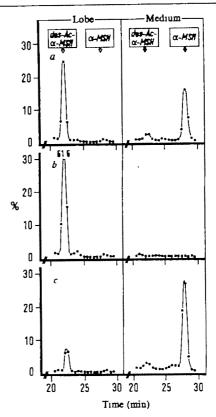

Fig. 3 Effect of dopamine and cyclic AMP on the release of newly synthesized des-N $\alpha$ -acetyl- $\alpha$ -MSH and  $\alpha$ -MSH. Lobes were premcubated for 1 h before a 30-min pulse with <sup>3</sup>H-tryptophan, followed by chase incubations of 3.5 h m control incubation medium (a), medium containing  $10^{-5}$  M dopamine (3-hydroxytyramine HCl; Sigma) (b), or medium containing 6 mM cyclic AMP (8-bromo cyclic AMP, Sigma) (c). The HPLC fractions are expressed in percentages using the method described in Fig. 2 legend.

Cyclic AMP stimulates release of newly synthesized peptides from the pars intermedia of  $Xenopus^{10}$ . The present study shows that cyclic AMP treatment enhanced the amount of  $\alpha$ -MSH (Fig. 3c). Approximately 75% of the newly synthesized MSH was present in the  $\alpha$ -MSH form and, again, this form was found exclusively in the medium. Thus, stimulation of release was accompanied by stimulation of the acetylation process. Altogether, our results indicate that the acetylation of des- $N\alpha$ -acetyl- $\alpha$ -MSH occurs immediately before or during release.

The above results, dealing with newly synthesized peptides, suggest that  $\text{des-}N\alpha\text{-acetyl-}\alpha\text{-MSH}$  could constitute a 'storage-form' of the hormone. This contention is supported by observations we made concerning stored peptides (unpublished data). Using bioassays, we demonstrated that the pars intermedia of white-adapted *Xenopus*, which is known to store melanotropic peptides<sup>3</sup>, contains ~10 times more des- $N\alpha$ -acetyl- $\alpha$ -MSH than  $\alpha$ -MSH. Further, infusing animals adapting to a white background with <sup>3</sup>H-lysine resulted in a preferential accumulation of radioactive des- $N\alpha$ -acetyl- $\alpha$ -MSH such that after 10 days >90% of the radioactive MSH in the pars intermedia was in the non-acetylated form.

Des- $N\alpha$ -acetyl- $\alpha$ -MSH shows considerably less melanotropic activity than  $\alpha$ -MSH<sup>11</sup>. That acetylation of peptide hormones need not always be accompanied by an increase in activity is, however, illustrated by the fact that  $\beta$ -endorphin is not biologically active in its acetylated form<sup>12</sup>. It is interesting that  $\alpha$ -MSH and  $\beta$ -endorphin are derived from the same prohormone<sup>13,14</sup>. Whether acetylation constitutes a control point in regulating the biological potency of pars intermedia peptides, as suggested earlier<sup>12</sup>, remains to be established.

In the rat pituitary gland, Woodford and Dixon<sup>15</sup> demonstrated the presence of  $N\alpha$ -acetyltransferase, which can acetylate the  $\alpha$ -amino group of synthetic des- $N\alpha$ -acetyl- $\alpha$ -MSH to form  $\alpha$ -MSH. The acetylation reaction reported in the present investigation is probably catalysed by such an enzyme. As this

acetylation is closely related to the release process, the enzyme is probably associated with the secretory granules or with the cell membrane. This situation would be unique, as most acetylations of polypeptides take place before or during packaging in the secretory granules 12,16; a pertinent example is the  $N\alpha$ -acetylation of  $\beta$ -endorphin in the rat pars intermedia<sup>17</sup>

The process of exocytosis implies the fusion of the membrane of the secretion granule with the plasma membrane1 Membrane fusion, in general, may be accompanied by physical and chemical changes in the membranes involved<sup>19</sup>. An intriguing possibility for the acetylation of des- $N\alpha$ -acetyl- $\alpha$ -MSH in the amphibian pars intermedia is that during the secretory process physicochemical changes in the microenvironment near the cell membrane lead to activation of a specific  $N\alpha$ -acetyltransferase, thus linking acetylation of the hormone to its release.

#### The regulatory subunit of adenylate cyclase interacts with cytoskeletal components

#### Mark M. Rasenick\*, Peter J. Stein & Mark W. Bitensky

Department of Pathology, Yale University School of Medicine, New Haven, Connecticut 06510, USA

The adenylate cyclase system, which mediates cellular responses to a variety of hormones and neurotransmitters, contains at least three plasma membrane-associated proteins: the hormone receptor, the regulatory or guanyl nucleotide-binding unit (G unit) and the catalytic moiety. Activation of the enzyme after binding of hormone to the receptor involves binding of GTP to the G unit1. Activation can be enhanced by increasing the fluidity of the membrane with unsaturated fatty acids2 with the local anaesthetic prilocaine3, and perhaps, in vivo, by phospholipid methylation<sup>4</sup>. Disruption of microtubules increases localized mobility of membrane proteins in a manner similar to that of unsaturated fatty acids<sup>5</sup> and can enhance cyclic AMP accumulation in intact leukocytes<sup>6-9</sup>. We therefore decided to investigate whether there is a direct interaction between microtubules and adenylate cyclase. We show here that colchicine, vinblastine and cis-unsaturated fatty acids enhance G unitmediated activation of adenylate cyclase, implying that microtubules or tubulin are involved in the attachment of the G unit to the membrane.

Incubated (before assay) with:

Fig. 1 Adenylate cyclase activity in synaptic membranes preincubated with fatty acids or microtubule-disrupting agents. Enriched synaptic membrane fractions (ESMF) were prepared from 21-day old male Sprague-Dawley rats by a modification  $^{25}$  of the method of Gray and Whittaker  $^{26}$ . After washing the 10,000~gpellet three times in a 0.32 M sucrose, 20 mM Tris-maleate pH 7.8, 5 mM MgSO<sub>4</sub>, 2 mM EGTA, 1 mM dithiothreitol (DTT) buffer, the membranes (about 80-85% synaptosomes by electron microscopy) were stored under liquid nitrogen. After thawing, synaptosomes were lysed in 20 mM Tris-maleate pH 7.8, 5 mM MgSO<sub>4</sub>, 1 mM DDT (1.2 mg protein per ml) and treated at 30 °C, 20 min with compounds a-h as indicated. 40 µl of the membrane suspension were then incubated (30 °C, 20 min) with 10 µl of Gpp(NH)p, NaF, Mn<sup>2+</sup> or H<sub>2</sub>O. Adenylate cyclase assays<sup>25</sup> are started by the addition of ATP and a regenerating system (100  $\mu l$ total volume), carried out for 10 min at 30 °C and stopped by boiling. Cyclic AMP produced is assayed by protein binding<sup>27</sup> using a rabbit skeletal muscle-binding protein<sup>28</sup>. Values are the means of triplicate determinations in one of four similar experiments. a,  $H_2O$ ; b, colchicine  $10^{-6}$  M; c, vinblastine  $10^{-6}$  M; d, lumicolchicine  $10^{-5}$  M; e, cis-vaccenic acid  $10 \,\mu g \, \text{ml}^{-1}$ ; f, linoleic acid  $10 \,\mu g \, \text{ml}^{-1}$ ; g, stearic acid  $10 \,\mu g \, \text{ml}^{-1}$ ; h, linoleic acid + colchicine.

In enriched synaptic membrane fractions (ESMF) from rat cerebral cortex, the G unit (with GTP) can interact directly with the catalytic moiety to activate adenylate cyclase. In this case, the hormone receptor is functionally bypassed 10,11 and the interaction of two, rather than three, subunits can be examined while the regulatory role of the G unit is maintained. Thus when fluoride or guanylylimidodiphosphate (Gpp(NH)p-a hydrolysis-resistant GTP analogue) is present, adenylate cyclase is stably activated by the G unit-catalytic moiety complex. Manganese, however, can bypass the G unit to activate the catalytic moiety directly12.

In an attempt to increase the G unit-catalytic moiety interaction by increasing the mobility of the proteins, ESMF were incubated with colchicine ( $K_a 5 \times 10^{-7} \text{ M}$ ) or vinblastine and the effects of these agents on Gpp(NH)p or fluoride activation of adenylate cyclase was examined. In these conditions, adenylate cyclase activity is significantly increased (Fig. 1). Lumicolchicine, which does not bind to tubulin<sup>13</sup>, does not have this effect at any concentration. Incubation with membrane fluidizers such as cis-vaccenic or linoleic acid is approximately as effective as colchicine or vinblastine in elevating Gpp(NH)p or NaF activation of adenylate cyclase. The effects of fatty acids and colchicine are not additive. When fatty acids, colchicine or vinblastine were added, they did not alter the catalytic activity as determined by activity in the presence of manganese.

Membranes that have been incubated with colchicine or vinblastine, and subsequently washed, show a loss of Gpp(NH)p or NaF-mediated adenylate cyclase activity. Treatment of ESMF with cis-vaccenic acid, however, continues to enhance adenylate cyclase activity even after the membranes have been washed. Again the intrinsic catalytic activity, as measured with manganese, was not altered by these treatments (Fig. 2).

To test whether any material that may have been stripped from the membrane during colchicine preincubation would restore or enhance Gpp(NH)p and fluoride sensitivity, we added back concentrated, dialysed supernatants from the washes following preincubation with colchicine. We found that both the control supernatant (data not shown) and, to a greater extent, the colchicine preincubation supernatant (dialysed free of colchicine and guanyl nucleotide) augmented adenylate cyclase activity (both basal and in the presence of Gpp(NH)p or fluoride: Flg. 3). These data suggest that the G unit may be liberated from the synaptic membrane.

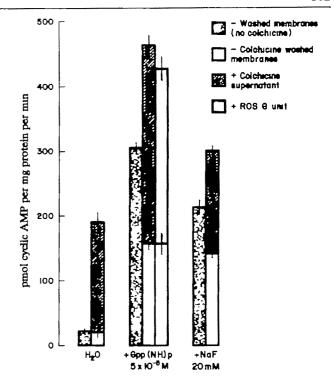

Previous experiments in this laboratory have indicated that the GTPase complex (G unit) from amphibian or bovine photoreceptor rod outer segment cyclic GMP phosphodiesterase (ROS-PDE) is similar to the G unit of adenylate cyclase <sup>14</sup>, and that ESMF adenylate cyclase can be activated by photoreceptor components<sup>15</sup>. The ROS G unit becomes a stable activator of ROS-PDE or adenylate cyclase when Gpp(NH)p is bound in place of GTP<sup>16,17</sup>. Thus, when purified preparations of ROS G unit are added to ESMF which have been depleted of guanyl nucleotide or fluoride responsiveness by colchicine, Gpp(NH)p and NaF responsiveness is restored. The degree of restoration is comparable with that observed when concentrated supernatants from membranes preincubated with colchicine and subsequently washed (colchicine/wash supernatant) are added to ESMF (Fig. 3).

While the ability to add back Gpp(NH)p and fluoride responsiveness to colchicine-treated ESMF gives a qualitative indica-

Adenylate cyclase assayed in the presence of.

Fig. 2 Preincubation of synaptic membranes with microtubule-disrupting agents or fatty acids followed by washing effects on adenylate cyclase. ESMF were treated (as in Fig. 1) with the indicated compounds and then washed twice with 10 volumes of 10 mM Tris-maleate pH 7.8, 2 mM EDTA, 1 mM DTT followed by centrifugation at 10,000g for 15 min (4 °C). Membranes were resuspended and assayed for adenylate cyclase in the presence of H<sub>2</sub>O, Gpp(NH)p, NaF or MnSO<sub>4</sub> as noted for 10 min at 30 °C. Values are means of triplicate determinations for one of three similar experiments. Fluoride activation is lower than that shown in Fig. 1, as NaF is present only during the assay step<sup>25</sup>. a, No addition; b, colchicine 5×10<sup>-6</sup> M; c, vinblastine 5×10<sup>-6</sup> M; d, humicolchine 10<sup>-5</sup> M; e, cts-vaccenic acid 10 μg ml<sup>-1</sup>.

Adenylate cyclase assayed in the presence of:

Fig. 3 Reconstitution of adenylate cyclase activity with soluble components. Supernatants were prepared by incubating ESMF from 12 cerebral cortices with  $10^{-5}\,\mathrm{M}$  Gpp(NH)p ( $\pm5\times10^{-6}\,\mathrm{M}$ colchicine) for 20 min at 30 °C and washing with 10 mM Trus-maleate pH 7.8, 2 mM EDTA, 1 mM DTT. The process was repeated twice and the three 10,000g supernatants pooled and centrifuged for 1 h at 105,000g. The resulting supernatant was concentrated and dialysed free of Gpp(NH)p or colchicine in an Amicon Cf 25 cone (molecular weight cut-off ~25,000) in 20 mM Tris-maleate pH 7.8, 5 mM MgSO<sub>4</sub>, 1 mM DTT. 10 µl of a 0.74 mg protein per mi solution were added where indicated. ROS G unit was prepared (as described elsewhere  $^{29}$ ) by exposing toad (Bufo marinus) ROS to light and  $2 \times 10^{-6}$  M Gpp(NH)p. The ROS G unit consists of three polypeptides with apparent molecular weights of 39,000, 37,000 and 10,000, and these three species comprise >99% of the material added. The supernatant was concentrated (as above for ESMF) and 10 µl of a 0.12 mg protein per ml solution were added where indicated. Both the ROS G unit and the ESMF supernatants are devoid of adenylate cyclase and PDE activity, and do not alter the PDE activity of the ESMF.

tion that G unit activity can be lost and replaced, it is necessary to quantify the replacement. Towards this end, endogenous G unit activity was depleted with differential heat inactivation<sup>18</sup>. When ESMF are heated at 42 °C for 30 min, about 15% of Gpp(NH)p or NaF-mediated adenylate cyclase activity is retained compared with about 54% of catalytic activity (as monitored with Mn<sup>2+</sup>). Colchicine/wash supernatant or ROS G unit are capable of restoring the Gpp(NH)p and NaF response of heated membranes to a level concomitant with that of remaining catalytic activity (Fig. 4).

Activation of adenylate cyclase by ROS G unit and colchicine/wash supernatant saturates at 0.012 and 0.074 mg protein per ml respectively. Note that higher amounts of purified ROS G than endogenous G unit are required to reconstitute adenylate cyclase activity within the ESMF. This may be because ROS G is less able to insert successfully into the adenylate cyclase syncitium than is the native G unit. Nonetheless, it appears that the maximal Gpp(NH)p or NaF responsiveness conferred by added ROS G unit or colchicine/wash supernatant is limited by the Mn<sup>2+</sup>-determined catalytic activity (data not shown).

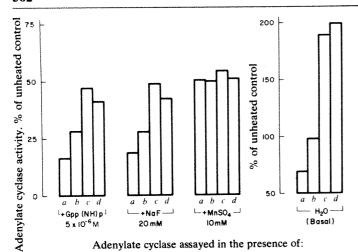

Fig. 4 Restoration of partially heat-inactivated adenylate cyclase activity with soluble synaptic membrane and rod outer segment components. ESMF were incubated at 42 °C for 30 min before assay for adenylate cyclase activity. Synaptic membrane supernatant (±colchicine) or ROS G unit (prepared as described in Fig. 3 legend) were added to the ESMF. The membranes were then assayed for adenylate cyclase (as described in Fig. 3 legend). Values are means of triplicate determinations from one of four similar experiments and are expressed as % of unheated controls. Unheated control values are: H<sub>2</sub>O, 43 pmol cyclic AMP per mg protein per min; Gpp(NH)p (5×10<sup>-6</sup> M), 290; NaF (20 mM), 231;

MgSO<sub>4</sub> (10 mM), 547. Supernatant additions: a, none; b, +control (no colchicine); c, +colchicine; d, +ROS G unit.

Figure 4 shows that Gpp(NH)p cannot reconstitute G unitmediated adenylate cyclase activation without added ROS G unit or synaptic membrane supernatant; increasing Gpp(NH)p (beyond  $5 \times 10^{-6}$  M) has no effect on adenylate cyclase activity. The supernatants, however, are capable of conferring additional guanyl nucleotide stimulation. ROS G unit or colchicine/wash supernatant charged with GDP do not increase basal adenylate cyclase activity in the differentially heat inactivated membranes (data not shown). When colchicine/wash supernatant or ROS G unit are heated (90 °C, 5 min) and added back to differentially heat-inactivated synaptic membranes, adenylate cyclase activities do not differ significantly from control (no supernatant added) values. Thus, these data indicate not only that free nucleotide is not responsible for restoration of adenylate cyclase activity, but that a heat-labile macromolecule with bound Gpp(NH)p is required.

The data presented here demonstrate that both free fatty acids and microtubule-disrupting agents enhance activation of rat synaptic membrane adenylate cyclase. Membrane-fluidizing lipids<sup>2,19</sup> or the local anaesthetic prilocaine<sup>3</sup>, and colchicine or are reported to activate adenylate cyclase in a vinblastine<sup>6-9</sup> number of cellular systems, and this activation seems to be distal to the hormone receptors<sup>2,3,8</sup>. The interaction of vinblastine at the G unit has been suggested to explain the biphasic effects of that compound in rat liver plasma membranes<sup>20</sup>. Our data suggest that the locus of the fatty acid and microtubule disruptor stimulation of synaptic membrane cyclase is at the G unit, as manganese response is not affected by these agents.

It is possible that the colchicine-mediated loss of Gpp(NH)p or fluoride responsiveness is due to a release of the G unit from the membrane. The ability to add back the same amount of G unit activity with colchicine/wash supernatant as with photoreceptor G unit supports this idea.

Most attempts to isolate the G unit have used detergents<sup>12</sup>. However, low salt washes can dislodge some G unit from the pigeon erythrocyte membrane<sup>21</sup>, there may be a soluble or a loosely attached G unit in liver cells<sup>22</sup> and previous experiments have observed a soluble factor which augments GTP or hormone sensitivity in liver plasma membranes23. The data presented here indicate that a subset of (though not necessarily all) G units may have a colchicine sensitive attachment to the synaptic plasma membrane.

The facilitation of G unit-mediated adenylate cyclase activity with either free fatty acids or microtubule-disrupting agents (without washing) suggests that the ability of the G unit to diffuse laterally in the membrane is a limiting factor in cyclase activation; that is, agents known to increase freedom of protein mobility in the membrane consequently increase cyclase activation. This effect may occur as a result of an increase in whole membrane fluidity or as a local effect at the site of G unit anchoring. Linoleic and cis-vaccenic (but not stearic) acids increased adenylate cyclase activity in these studies. The two former compounds (but not the latter) have recently been demonstrated to block lymphocyte capping in a manner similar to colchicine. In this sense, the fatty acids and microtubule disruptors might release constraints and enhance membrane protein mobility within localized domains5. A localized increase in membrane fluidity has similarly been proposed to explain the prilocaine augmentation of fluoride activated hepatic adenylate cyclase3

Loss of G unit activity mediated by colchicine or vinblastine but not fatty acids may be explained if one hypothesizes a microtubule (or membrane tubulin<sup>24</sup>) attachment site. We propose that fatty acids and microtubule-disrupting agents activate adenylate cyclase by different mechanisms. cis-Unsaturated fatty acids may increase membrane protein mobility, increasing the probability of effective G unit interaction with a catalytic moiety. Colchicine or vinblastine, however, may free the G unit from an attachment site, thus facilitating G unit-catalytic moiety interaction (and loss of G unit after washing). As not all the G unit activity can be eluted by colchicine, even after repetitive washing, it is likely that not all G units have a microtubule or tubulin attachment site. These data support a possible cytoskeletal-adenylate cyclase interaction and suggest additional possibilities for the control of adenylate cyclase activity.

We thank Drs H. Malech, J. Morrow and D. U'Prichard for critical reading of this manuscript and Dr R. Sorbi for helpful discussions. This work is supported by NIH grant AM 20179. M.M.R. is the recipient of a NIH postdoctoral Fellowship AM

### A single amino acid change in IFN- $\beta_1$ abolishes its antiviral activity

#### H. Michael Shepard\*, David Leung\*, Nowell Stebbing† & David V. Goeddel\*

Departments of \*Molecular Biology and †Biology, Genentech Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA

The cloning and expression of human fibroblast interferon (IFN- $\beta_1$ ) cDNA sequences in Escherichia coli have been reported by several groups 1-3; this will allow extensive study of its biological and physical properties. Aside from the cloning and expression of interesting and useful cDNA sequences, recombinant DNA techniques make possible the in vitro construction of gene sequences encoding novel polypeptides which do not occur naturally 4,8, which is difficult to achieve by direct chemical modification of proteins. We describe here the isolation of an IFN- $\beta_1$  cDNA sequence encoding the 117 Cterminal amino acids of a variant IFN- $\beta_1$  (Cys  $\rightarrow$  Tyr at amino acid position 141) and in vitro recombination with sequences coding for the N-terminal amino acids of IFN- $\beta_1$  to form a DNA sequence encoding a mature variant IFN- $\beta_1$  polypeptide, and its expression in E. coli. We show that the replacement of Cys at position 141 with Tyr inactivates antiviral activity in a cytopathic effect (CPE) inhibition assay and that the variant protein does not compete with normal fibroblast interferon for reaction with heterospecific antibodies to IFN- $\beta_1$ . These effects are attributed to an alteration in protein structure of IFN- $\beta_1^{Cyn-Tyn}$  which result from its inability to form an essential disulphide bond.

In our efforts to isolate a recombinant plasmid containing the cDNA sequences encoding human fibroblast interferon (IFN- $\beta_1$ ), several partial-length cDNA clones were obtained<sup>3</sup>. Among these is pF526, which is ~640 base pairs (bp) long and contains the poly(A) sequence, the 3'-untranslated region and about two-thirds of the coding region for the mature IFN- $\beta_1$  protein. DNA sequence analysis showed two changes from the published sequence of IFN- $\beta_1$  (Fig. 1; refs 1-3). The first involves the deletion of nucleotides 762-764 (GTC) immediately preceding the poly(A) in the 3'-noncoding region and may be due to normal variation in processing/polyadenylation of the primary transcript. The second change is a  $G \rightarrow A$  transition at position 485 of the published sequence, which lies within the coding region for the mature polypeptide and results in the replacement of a cysteine (TGT) codon with a tyrosine (TAT) codon. Because all the leukocyte interferons (IFN- $\alpha$ ) described to date<sup>6</sup> have a cysteine residue which can be aligned with the cysteine at position 141 of IFN- $\beta_1$  and as this cysteine is involved in disulphide bond formation in the IFN- $\alpha$  family<sup>7</sup>, it seemed likely that IFN- $\beta_1^{C_{T}\to T_{T}}$  might be a useful variant for investigating the structure of the IFN- $\beta_1$  molecule in relation to its antiviral activity.

As the cDNA insert of pF526 comprises only a partial copy of the IFN- $\beta_1$  mRNA and encodes only the 117 C-terminal amino acids of the mature polypeptide (Fig. 1), it was necessary to prepare a hybrid gene containing DNA sequences for the N-terminal 56 amino acids of the mature polypeptide and pF526 sequences encoding the remaining 110 acids. As shown in Fig. 2, pFIF  $tp^3$  69 (ref. 3) is a pBR322 derivative which carries three tp promoter fragments all oriented so that transcription occurs towards the cDNA insert encoding mature IFN- $\beta_1$ . The IFN- $\beta_1$  cDNA expression insert is bounded by XbaI (5') and BgIII (3') restriction endonuclease sites<sup>3</sup>. We removed the XbaI-BgIII insert from pFIF  $tp^3$  69, discarded the 3' HgaI-BgIII gene fragment and replaced it with the corresponding sequences from the variant. The recombined sequences were inserted into the original expression vehicle containing three promoters to

Fig. 1 The normal and variant IFN- $\beta_1$  cDNA sequences. Numbers above each line refer to nucleotide position, and numbers below refer to amino acid residue (S, signal peptide). The variant cDNA clone is underlined. The G $\rightarrow$ A transition is indicated by an arrow at position 485. The three nucleotides deleted in pF526 are indicated by asterisks above the normal sequence at positions 762–764. These cDNAs were cloned and isolated as described elsewhere<sup>3</sup>.

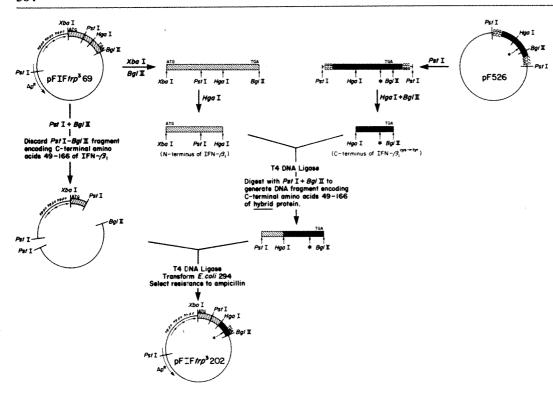

achieve maximal expression (Fig. 2). Restriction endonuclease and DNA sequence analysis of the new expression plasmid, pFIF  $trp^3$  202, showed that the promoters, the ribosome binding site and the entire hybrid coding region gene were arranged correctly (results not shown).

The interferon activity present in lysates of E. coli 294 containing the wild-type (pFIF trp<sup>3</sup> 69) and variant (pFIF trp<sup>3</sup> 202) expression plasmids as measured in a CPE inhibition assay<sup>3</sup>, was  $1.6 \times 10^4$  U ml<sup>-1</sup> for  $294/pFIF trp^3$  69 extracts but <21 U ml<sup>-1</sup> for extracts prepared from 294/pFIF trp<sup>3</sup> 202 (Table 1). Because the Cys → Tyr alteration may have affected the folding of the polypeptide, rendering it more labile to E. coll proteases, it was necessary to show that a stable protein with some of the properties of IFN- $\beta_1$  was detectable in extracts prepared from E. coll. As biosynthetic fibroblast interferon comprises <0.1% of E. coli protein it was not possible to show that equivalent amounts of both proteins were present in the extracts used for the initial assays shown in Table 1. To confirm that IFN- $\beta_1^{\text{Cyp-Tyr}}$  was inactive we synthesized both proteins in a coupled in vitro transcription-translation system derived from E. coli PR13 (ref. 8). Both pFIF trp<sup>3</sup> 69 and pFIF trp<sup>3</sup> 202 were used to programme the in vitro system and the products were analysed by SDS-polyacrylamide gel electrophoresis (Fig. 3) and tested for antiviral activity. Equivalent amounts of both wild-type and variant proteins were synthesized in vitro (Fig. 3).

Table 1 Antiviral activities of wild-type and variant IFN- $\beta_1$ 

Sample	Dilution of lysate	Interferon activity (U ml <sup>-1</sup> )
FIFN trp <sup>3</sup> 69 FIFN trp <sup>3</sup> 69 FIFN trp <sup>3</sup> 202 FIFN trp <sup>3</sup> 202 FIFN trp <sup>3</sup> 202 FIFN trp <sup>3</sup> 202	10 <sup>-1</sup> 10 <sup>-2</sup> - 10 <sup>-1</sup> 10 <sup>-2</sup>	1.6×10 <sup>4</sup> 1.3×10 <sup>3</sup> 1.7×10 <sup>2</sup> <21 <21 <21

Lysates were prepared and assayed by CPE inhibition<sup>3</sup>. Different dilutions are shown to indicate the range of variability in the assay.

2 Construction of IFN- $\beta_1$ expression plasmid. The starting materials were constructed as described elsewhere<sup>3</sup>. All enzymes were from New England Biolabs and digestions were done in 60 mM Tris pH 7.5. 6 mM MgCl<sub>2</sub>, 60 mM NaCl and 6 mM 2mercaptoethanol at 37 °C. Ligations were done overnight at 12°C in 60 mM Tris pH 7.5, 3 mM MgCl<sub>2</sub> and 10 mM dithiothreitol. Transformations done as described pre-viously<sup>3</sup>. Transformed Transformed cells were selected on LBagar plates containing 20 µg ml<sup>-1</sup> ampicillin to ensure that only clones containing plasmids with the correct structure were recovered. Arrows within plasmids represent trp promoter fragments and their direction of transcription. Cross-hatched blocks represent wildtype coding sequences and shaded blocks variant coding sequences.

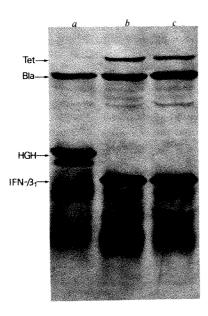

Fig. 3 In vitro synthesis of normal and variant IFN- $\beta_1$ . Plasmids encoding human growth hormone (a), IFN- $\beta_1^{\text{Cys-Tyr}}$  (b) and wild-type IFN- $\beta_1$  (c) were used to programme a coupled in vitro transcription-translation system. The top two bands in each case are the plasmid-encoded protein for tetracycline resistance (Tet; molecular weight  $(M_r)$  36,000) and  $\beta$ -lactamase (Bla; $M_r$  32,000). The lower band in a is human growth hormone (HGH;  $M_r$  22,000) encoded by a plasmid similar in structure to the expression plasmids encoding the variant and wild-type IFN- $\beta_1$  ( $M_r$  20,000). The in vitro system used was that described in ref. 8. Plasmid DNA (5  $\mu$ g) was added to a total reaction volume of 25  $\mu$ l. 5  $\mu$ l of each reaction mixture was analysed by electrophoresis through a 15% SDS-polyacrylamide gel<sup>12</sup> and subsequently fluorographed as described by Bonner and Laskey<sup>13</sup>. 10  $\mu$ l of each reaction mixture was used to determine antiviral activity in a CPE inhibition assay<sup>3</sup>.

When aliquots of the *in vitro* reactions were used in a CPE inhibition assay, extract programmed by pFIF  $trp^3$  69 yielded  $3 \times 10^3$  U ml<sup>-1</sup> IFN- $\beta_1$  antiviral activity, whereas pFIF  $trp^3$  202 extracts had no detectable activity.

Although the variant fibroblast interferon, IFN- $\beta_1^{\text{Cys} \rightarrow \text{Tyr}}$  shows no antiviral activity it might still compete with the other form of IFN- $\beta_1$  in binding antibodies against fibroblast interferon. Incubation of IFN- $\beta_1$  with up to a 1,000-fold excess of IFN- $\beta_1^{\text{Cys} \rightarrow \text{Tyr}}$  and sufficient heterospecific rabbit anti-fibroblast interferon antibodies (obtained from the Antiviral Substances Program of the National Institutes of Allergy and Infectious Diseases) to neutralize the wild-type IFN- $\beta_1$  only, no antiviral activity was observed (data not shown). These results indicate that the amino acid change in IFN- $\beta_1^{\text{Cys} \rightarrow \text{Tyr}}$  disrupts the structure of the molecule sufficiently to prevent it from binding antibody specific for that part of the protein essential for induction of antiviral activity in target cells.

The Cys  $\rightarrow$  Tyr change introduced in the fibroblast interferon variant described here could disrupt the function of the molecule in a number of ways, for example, by altering the strength of intramolecular hydrogen bonding or hydrophobic interactions. However, because preincubation of IFN- $\beta_1$  extracts with dithiothreitol completely abolishes antiviral activity in a CPE inhibition assay (H.M.S., unpublished observations), it is likely that the disulphide bond between Cys 31 and Cys 141 is essential to maintain the structure of IFN- $\beta_1$  required for antiviral activity. Our data therefore suggest that the altered structure of IFN- $\beta_1$  revents it from binding to cell membrane receptors, an interaction which mediates the antiviral activity of interferon.

Variant interferons have been found in the leukocyte interferon family, notably two forms of LeIFN H, which could represent allelic forms<sup>6</sup>. Between the IFN- $\alpha$  species A and D there are a total of 29 amino acid differences<sup>6</sup>. Of these, three occur within the region which is most conserved among the IFN- $\alpha$  species (between amino acids 115 and 151; refs 6, 10). Therefore, some amino acid sequence changes within this conserved region are tolerated, although the cysteine at position 139 (141 of IFN- $\beta_1$ ) may be essential for antiviral activity

(R. Wetzel, personal communication). Because the 5'-terminal sequences of IFN-β<sub>1</sub><sup>Cys - Tyr</sup> are unknown it is uncertain whether it is analogous to the variants of the leukocyte interferon family. It is possible that the  $G \rightarrow A$  transition at nucleotide 486 (Fig. 1) is the result of a reverse transcription error and does not occur naturally. Of four partial-length cDNA clones that were obtained from the human fibroblast cell line GM-2504A (ref. 3), only pF526 had the Cys → Tyr change at amino acid 141 and the deletion of nucleotides 762-764 immediately preceding the polyadenylation site. In any case it is possible that the variant IFN- $\beta_1$  mRNA identified by cDNA cloning is not normally translated, or if it is, it could be biologically active by virtue of some compensating changes in the unknown segment of the gene. The variant IFN- $\beta_1$  gene cannot correspond to the proposed second fibroblast interferon gene (IFN- $\beta_2$ ) because IFN- $\beta_2$  sequences show little or no cross-hybridization with IFN- $\beta_1$ (ref. 11). Cell membrane binding studies are in progress to determined directly whether IFN- $\beta_1^{\text{Cys} \rightarrow \text{Tyr}}$  is unable to bind cell receptors.

#### Non-muscle $\alpha$ -actinins are calcium-sensitive actin-binding proteins

Keith Burridge\* & James R. Feramisco

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA

Many actin-binding proteins have been purified from different cell types, and a number of them share certain features: they are affected by calcium in their interaction with actin and have similar subunit molecular weights (~100,000) on SDS-polyacrylamide gels. These proteins have been given various names, including gelsolin<sup>1-3</sup>, villin<sup>4,5</sup>, actinogelin<sup>6,7</sup>, *Dictyostelium* 95K protein<sup>8,9</sup>, platelet 95K protein<sup>10</sup> and *Acanthamoeba* 85K protein<sup>11</sup>. The actin-binding protein α-actinin has received little attention in this analysis, even though it has a subunit molecular weight in this range ( $\sim 100,000$ ) and has been shown immunologically to exist in non-muscle cells<sup>12,13</sup>. Here we report that  $\alpha$ -actinin purified from HeLa cells is inhibited from crosslinking actin filaments by micromolar free calcium. In many properties it closely resembles actinogelin, Dictyostelium 95K protein and Acanthamoeba 85K protein, but it appears distinct from proteins such as gelsolin and villin which, in the presence of calcium, fragment actin filaments into short oligomers<sup>3</sup> conclude that in this molecular weight range there are at least two classes of non-muscle actin-binding protein: one corresponding to non-muscle  $\alpha$ -actinins and the other to proteins such as gelsolin and villin.

α-Actinin has been purified from cultured HeLa cells using a modification of the procedure we developed for the purification of  $\alpha$ -actinin from smooth muscle<sup>14</sup>. Chromatography of this  $\alpha$ -actinin on hydroxyapatite resulted in the separation of two

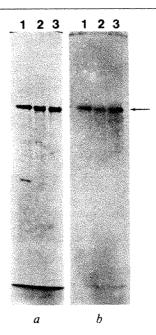

Fig. 1 SDS gel analysis of HeLa cell  $\alpha$ -actinins and  $\alpha$ -actinins from chicken gizzard smooth muscle. a, A 10% polyacrylamide SDS gel stained with Coomassie blue on which were electrophoresed 4µg of the following proteins: track 1, smooth muscle α-actinin; track 2, HeLa α-actinin I; track 3, HeLa α-actinin II. The slight difference in molecular weight between the two forms of HeLa cell α-actinin is not detectable at this level of protein loading on the gel. b, An autoradiograph of the same gel slice after staining the gel with antibodies against beef cardiac  $\alpha$ -actinin followed by a second radio-iodinated antibody directed against the first antibody. Note that the antibody against  $\alpha$ -actinin labels all three proteins. This antibody has been characterized previously<sup>18</sup> and only a tight doublet of bands corresponding to the two  $\alpha$ -actinins is labelled when a gel of total HeLa cell proteins is stained with this antibody <sup>18</sup>. The gel staining with antibody was performed as described elsewhere <sup>19</sup>. SDS-gel electrophoresis was performed using Laemmli's buffer conditions <sup>20</sup>.

forms with slightly different subunit molecular weights on SDS gels (~102,000 and 100,000). The detailed description of the purification and characterization of these two forms of HeLa α-actinin will be described elsewhere (J.R.F. and K.B., in preparation). Figure 1 shows SDS-polyacrylamide electrophoretic gels of the two forms (referred to here as HeLa  $\alpha$ -actinin I and HeLa  $\alpha$ -actinin II) next to a sample of smooth muscle  $\alpha$ -actinin (Fig. 1a). An autoradiograph of the same gel is also shown (Fig. 1b) after incubation with antibody against muscle α-actinin followed by incubation with a second radioiodinated antibody directed against the first antibody. This indicates that both HeLa proteins cross-react immunologically with muscle  $\alpha$ -actinin. In addition to their similar purification properties, subunit molecular weights on SDS gels and crossreaction with antibodies to muscle  $\alpha$ -actinin, these two HeLa proteins have been identified as  $\alpha$ -actinin by several criteria that will be described in detail elsewhere (J.R.F. and K.B., in preparation). Briefly, both native proteins are dimers, with Stokes' radii and s values close to those of muscle  $\alpha$ -actinin. Their native peptide maps and amino acid composition are similar to but distinct from those of muscle  $\alpha$ -actinin. Both proteins bind to F-actin and this binding is diminished by tropomyosin at 37 °C. as is found with muscle  $\alpha$ -actinin. Unlike muscle  $\alpha$ -actinin, however, the binding to F-actin is markedly inhibited by low free calcium concentrations (Figs 2, 3). In low free calcium ( $<10^{-7}$  M), the two non-muscle  $\alpha$ -actinins

are potent actin gelation factors. The concentration of the  $\alpha$ -actinins that will cause gelation of F-actin (as determined by the failure of a stainless-steel ball to fall in the failing ball viscometer) varies between experiments and is dependent on conditions such as actin concentration, temperature and age of  $\alpha$ -actinin preparations. Typically, with F-actin at

<sup>\*</sup> Present address: Laboratories for Cell Biology, Department of Anatomy, University of North Carolina, Chapel Hill, North Carolina 27514, USA

Table 1	Classification of calcium-sensitive actin-binding proteins				
I	Non-muscle α-actinin class				
	HeLa α-actinins				
	Platelet 105K protein				
	Actinogelin				
	Dictyostelium 95K protein				
	Acanthamoeba 85K protein				
II	Gelsolin/villin class				
	Gelsolin				
	Villin				

The class I proteins cross-link F-actin at low calcium concentrations but are inhibited from cross-linking at high calcium concentrations. They appear to be rod-shaped proteins, and in some cases have been shown to be dimeric. The class II proteins are globular, monomeric proteins that in the presence of calcium fragment actin filaments into short oligomers.

Platelet 95K protein

 $0.2~{\rm mg~ml}^{-1}$  gelation is seen at an  $\alpha$ -actinin: actin molar ratio of 1:100-1:200, but at  $0.4~{\rm mg~ml}^{-1}$  F-actin gelation has been seen at a molar ratio of about 1:400 and this ratio will decrease still further as the actin concentration is increased.

The effect of different free calcium concentrations on the viscosity of mixtures of actin and  $\alpha$ -actinin is shown in Fig. 3. Smooth muscle  $\alpha$ -actinin is essentially unaffected by calcium concentrations in the range examined here. With the two forms of HeLa  $\alpha$ -actinin a sharp fall in the viscosity occurs when the free calcium concentration exceeds  $10^{-7}$  M. Note, however, that the viscosity only falls to the background level of the F-actin on its own, indicating that the cross-linking by  $\alpha$ -actinin has been inhibited. On the other hand, with a protein such as gelsolin in the presence of micromolar calcium and F-actin, the viscosity of the mixture decreases below the level of the F-actin control due

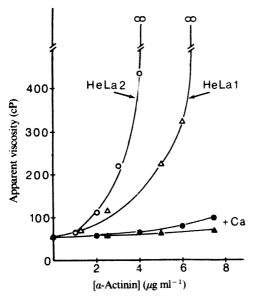

Fig. 2 Effect of varying concentration of HeLa  $\alpha$ -actinin on the viscosity of F-actin. The two forms of HeLa  $\alpha$ -actinin were added to preformed F-actin  $(0.2 \text{ mg mi}^{-1})$  at low  $(10^{-7} \text{ M})$  and high  $(10^{-4} \text{ M})$  free calcium.  $\triangle$ , HeLa  $\alpha$ -actinin I at low free calcium;  $\triangle$ , HeLa  $\alpha$ -actinin II at low free calcium;  $\bigcirc$ , HeLa  $\alpha$ -actinin II at high free calcium;  $\bigcirc$ , HeLa  $\alpha$ -actinin II at high free calcium. The final ionic conditions were 40 mM KCl, 1 mM MgCl<sub>2</sub>, 0.1 mM ATP, 0.275 mM EGTA, 0.1%  $\beta$ -mercaptoethanol, 10 mM PIPES,  $\beta$ H 7.0, for those measurements at  $<10^{-7}$  M free calcium, or for those measurements at  $10^{-4}$  M free calcium the same ionic conditions were used except that the EGTA was replaced by 0.1 mM CaCl<sub>2</sub>. Apparent viscosity was measured using the low-shear, falling ball viscometer  $^{21}$  at 21 °C, 2 h after mixing the samples. Note that in the presence of  $10^{-4}$  M calcium the viscosity remained essentially at the background level generated by F-actin alone (apparent viscosity = 56 cP), whereas below  $10^{-7}$  M calcium gelation was induced by  $\sim 5 \text{ μg ml}^{-1}$  of HeLa  $\alpha$ -actinin II or  $\sim 1.5 \text{ μg ml}^{-1}$  of HeLa  $\alpha$ -actinin II.

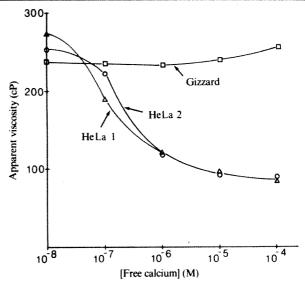

Fig. 3 Effect of varying free calcium concentration on the viscosity generated by mixing purified HeLa cell or chicken gizzard smooth muscle  $\alpha$ -actinins with F-actin. HeLa  $\alpha$ -actinin I  $(\triangle)$  was used at a final concentration of 5  $\mu$ g ml<sup>-1</sup>, HeLa  $\alpha$ -actinin II  $(\bigcirc)$ was used at 3.5  $\mu$ g ml<sup>-1</sup>, chicken gizzard smooth muscle  $\alpha$ -actinin ( $\square$ ) was used at  $\sim 10 \ \mu$ g ml<sup>-1</sup>. The  $\alpha$ -actinins were added to preformed F-actin, used at a final concentration of 0.2 mg ml The final ionic conditions were identical to those in Fig. 2 except the free calcium concentrations were generated using a Ca-EGTA buffer in which the EGTA concentration was maintained at 0.275 mM, apart from measurements of the values at 10 calcium, from which EGTA was omitted and replaced by 0.1 mM CaCl<sub>2</sub>. Free calcium concentrations were calculated using an apparent association constant for EGTA and calcium of log 6.68 (ref. 22). Any effect of 0.1 mM ATP was ignored in this calculation. Viscosity was measured using a falling ball viscometer at 23 °C 3 h after mixing the samples. The apparent viscosity of the F-actin without α-actinin was 78 cP and was unaffected by the different calcium concentrations. Note that in the higher free calcium concentrations the viscosity of the samples with either of the two HeLa  $\alpha$  -actinins fell to a level approaching that of the F-actin alone but did not fall below this value.

to the severing of the actin filaments to short oligomers by this protein<sup>3</sup>.

The two forms of  $\alpha$ -actinin from HeLa cells are very similar to the muscle  $\alpha$ -actining by all criteria so far examined, with the exception of this calcium-inhibited interaction with actin. In collaboration with Rosenberg and Stracher, we have recently demonstrated that a platelet protein of molecular weight 105,000 (105K protein) that is calcium sensitive in its binding to actin is the platelet  $\alpha$ -actinin<sup>15</sup>. The calcium sensitivity of both HeLa and platelet  $\alpha$ -actinins suggests that this is a general property of non-muscle  $\alpha$ -actinins. On examining the other actin-binding proteins in this molecular weight range, we note that several closely resemble the HeLa  $\alpha$ -actinins in response to calcium and in many of their other properties. Actinogelin closely resembles muscle  $\alpha$ -actinin in all physical properties examined so far (A. Asano, personal communication). Acanthamoeba 85K protein resembles a-actinin in being a rodshaped protein with a Stokes' radius of about 85 Å (ref. 11). Dictyostelium 95K protein is also rod-shaped and preliminary data indicate that, like a-actinin, it is dimeric (D. L. Taylor, personal communication). All these proteins cross-link F-actin in a manner that is inhibited by calcium<sup>7,8,11</sup>. On the other hand, proteins such as gelsolin and villin seem to be quite different, being globular, monomeric proteins that also bind to actin but, in the presence of calcium, fragment actin filaments to shorter oligomers<sup>2,3,5</sup>. We have, therefore, grouped these actin-binding proteins in Table 1 into two distinct classes: an  $\alpha$ -actinin class which would include the HeLa a-actinins of the present study, the platelet 105K protein, actinogelin, Dictyostelium 95K protein and Acanthamoeba 85K protein; and a second class that would include gelsolin and villin. As T. P. Stossel and his

colleagues have identified gelsolin-like proteins immunologically in a wide variety of different vertebrate cell types (personal communication), it may be that most higher eukaryotic cells contain representatives of both classes of protein. So far, a protein similar to gelsolin has not been identified in this molecular weight range in lower eukaryotes, and the equivalent function may be served by a protein of lower molecular weight. Such a protein, called fragmin, with an apparent molecular weight of 45,000, has been purified from Physarum 16,17, and a low molecular weight protein with similar properties has also been identified in Dictyostelium (J. Spudich, personal communication).

The difference between non-muscle  $\alpha$ -actinins and muscle α-actinins in their calcium-sensitive interaction with actin may reflect the different requirements of the muscle and non-muscle contractile systems. With muscle, a comparatively stable actin

lattice is required for efficient repeated contraction, but with most non-muscle cells movement is generally accompanied by a change of shape. It seems necessary that the cell's forcegenerating apparatus should be able to be disassembled and reorganized rapidly for movement to continue. Given this requirement, it may well be an advantage for a non-muscle cell to have an  $\alpha$ -actinin that will respond to a calcium flux. In the absence of calcium, non-muscle α-actinin would cross-link actin filaments to form a stable network, but in the presence of calcium it would release the actin filaments and so permit their rapid reorganization.

#### Myosin filaments have non-phosphorylated light chains in relaxed smooth muscle

A. V. Somlyo, T. M. Butler\*, M. Bond & A. P. Somlyo

Pennsylvania Muscle Institute, University of Pennsylvania, School of Medicine, B42 Anatomy-Chemistry Building/G3, Philadelphia, Pennsylvania 19104, USA Thomas Jefferson University, Department of Physiology, 1020 Locust Street, Philadelphia, Pennsylvania 19107, USA

The provocative hypothesis that myosin in resting smooth muscle is in a soluble form and assembles into filaments only at the time of contraction1,2 has been disproved with the demonstration of regular arrays of myosin filaments in a variety of smooth muscles, including those shown to have been relaxed before and during fixation3-7. Nevertheless, following the observations of Suzuki et al.8 on the effect of light-chain phosphorylation on smooth muscle myosin assembly in vitro, this hypothesis has been revived with the speculation that relaxed smooth muscle contains non-phosphorylated, non-filamentous myosin that assembles into filaments only after the muscles are stimulated and myosin is phosphorylated9. Here we have used rapid freezing techniques to avoid concerns about the possible effects of fixation on the in vivo form of myosin10 and demonstrate the existence of a myosin filament lattice in relaxed vascular smooth muscles in which we also show myosin light chain phosphorylation to be minimal (<5%).

Longitudinal strips of rabbit portal anterior mesenteric vein were attached to force transducers, stretched to physiological (1.75× slack) length, mounted in muscle baths at 37 °C in oxygenated Krebs solution and equilibrated for ~1 h. Some muscles were exposed for 1.5 min to 0.2 µg ml<sup>-1</sup> isoprenaline which is known to hyperpolarize and relax smooth muscle 11. The muscle bath was quickly lowered and a beaker of supercooled Freon 22 (ref. 12) was shot up to the muscle. The moment of impact was seen on the tension record that showed that the

Osmium crystals were added on warming and en bloc staining was done with uranyl acetate in methanol, which resulted in a negative staining effect in some of the outer cells. Arrows indicate myosin filaments surrounded by actin (thin) filaments. ×138,000.

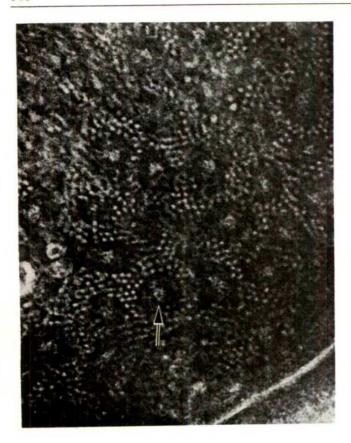

Fig. 2 Transverse cryosection of a rapidly frozen, briefly (15 min) glutaraldehyde-fixed muscle. The section was picked up on a drop of frozen sucrose in the cryo chamber, melted in a dry atmosphere and negatively stained with 1% ammonium molybdate. Myosin filaments (arrow) are surrounded by rosettes of actin filaments. ×200,000.

muscle remained relaxed. The strips were processed by freeze substitution  $^{13.14}$  for ultrastructural studies or analysed for the degree of myosin light chain phosphorylation. The phosphorylated and unphosphorylated forms of the 20,000 molecular weight chain (LC<sub>20</sub>) were separated by isoelectric focusing  $^{15}$  in urea–polyacrylamide gels followed by electrophoresis in SDS-containing slab gels in the second dimension  $^{16-18}$ .

In relaxed, freeze-substituted muscles (Fig. 1), myosin filaments were consistently observed in the well frozen surface cells (nine muscles). The number and distribution of myosin filaments were similar in rapidly frozen and chemically fixed muscles<sup>3,19</sup> (Figs 2, 3). The demonstration of thick filaments in the rapidly frozen freeze-substituted muscles renders highly unlikely the implication<sup>10</sup> that the use of glutaraldehyde fixation before freezing (Fig. 2) induces the formation of an array of myosin filaments.

Regular arrays of actin filaments were more difficult to maintain in the rapidly frozen muscles, due to disorder caused by minute ice crystals. Therefore, three muscles were preincubated in a cryoprotectant—10% bovine serum albumin, 10% ethylene glycol or 10% dimethyl sulphoxide in Krebs solution—for 5 min before the addition of isoprenaline. Ethylene glycol and dimethyl sulphoxide abolished the spontaneous contractions. Ethylene glycol provided the greatest depth of cryoprotection and preserved the order of the actin filaments (Fig. 4). In these preparations, the ratio of actin to myosin filaments was 12:1, similar to the ratios found in conventionally fixed muscles<sup>3,19</sup>.

The average  $LC_{20}$  phosphorylation in portal veins relaxed with isoprenaline (six animals) was less than 5% (Fig. 5a). An

additional three relaxed portal veins which were cryoprotected before freezing (Fig. 4) showed similarly low levels of LC20 phosphorylation as untreated resting muscles. In contrast to the relaxed muscles, significant levels of LC20 phosphorylation, ranging over 23-73%, were measured in muscles frozen 2-15 s after stimulation with a high K+ depolarizing solution (Fig. 5b, c), with an average time-to-peak tension after activation of 12 s. The absence of any significant phosphatase activity during extraction of contractile proteins was demonstrated in control experiments using purified gizzard actomyosin in which LC20 was ~80% phosphorylated (as shown by 32P incorporation): phosphorylated actomyosin was (1) ground up with frozen taenia coli before extraction, (2) extracted separately or (3) ground up with frozen taenia coli and incubated at room temperature for 20 min before extraction. In (1) and (2) at most 4% of the 32P label was released during the normal extraction procedure, while in case (3) almost all the labelled phosphate was released, as also demonstrated by the absence of phosphorylated LC20 in the two-dimensional gels. Other control experiments showed that there was no change in LC20 phosphorylation when the frozen homogenates were incubated for up to 4 h at room temperature in the solution (9.0 M urea, 5% mercaptoethanol) used for isoelectric focusing. These controls and the clear demonstration of phosphorylation of light chains in contracted muscle indicate that the extraction procedure and isoelectric focusing followed by SDS-gel electrophoresis provide an accurate estimate of the degree of LC20 phosphorylation.

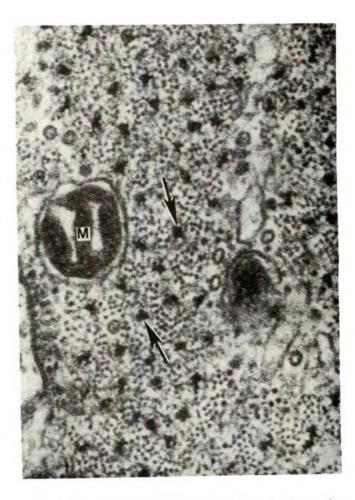

Fig. 3 Transverse section of an isoprenaline-relaxed smooth muscle, fixed in 2% glutaraldehyde followed by 2% tannic acid before post-fixation in osmium and *en bloc* staining with uranyl acetate. Arrows indicate myosin filaments; M, mitochondrion. ×148,000.

That most of the myosin in mature smooth muscle is in filamentous form is also supported by the close agreement between estimates of myosin content obtained by SDS gels<sup>7,20-22</sup> and by quantitative electron microscopy3,19. The same actin: myosin ratios in rabbit portal anterior mesenteric vein were obtained when measured by either SDS-gel electrophoresis or quantitative electron microscopy (P. F. Berner, A.V.S., A.P.S. and H. Holtzer, unpublished observations). We also note that short filaments ( $\sim 0.5 \mu m$ ) are produced by phosphorylation of myosin in vitro, unlike the 2.2-µm long filaments found in smooth muscle in situ 19

Thus, there is compelling evidence that myosin in resting smooth muscle is predominantly filamentous, even when the light chains are unphosphorylated, although we do not wish to extrapolate our findings to non-muscle cells. The rapid freezing techniques (refs 12, 23-25 and present study) that circumvent the objections that chemical fixation and associated changes in ionic strength, cation and nucleotide concentrations may induce the formation of myosin filaments also seem to be the most direct method of exploring the in situ state of myosin in nonmuscle cells.

We thank Dr S. Chacko for providing 32P-labelled turkey gizzard actomyosin. This work was supported by NIH grant HL15835 to the Pennsylvania Muscle Institute.

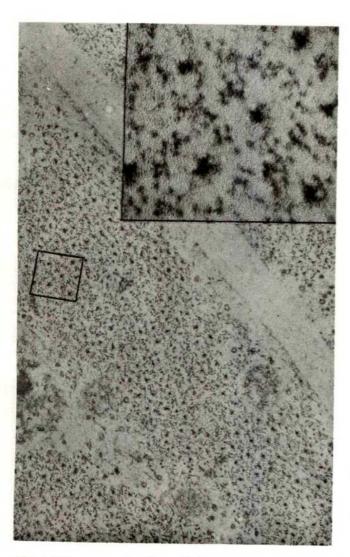

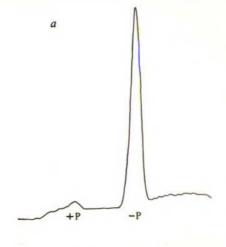

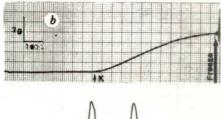

Fig. 4 Transverse section of a rapidly frozen isprenaline-relaxed smooth muscle which has been cryoprotected with 10% ethylene glycol. ×60,000. Inset: regular arrays of thick filaments occur which are surrounded by actin filaments shown at higher magnification (×330,000). LC20 phosphorylation in this muscle

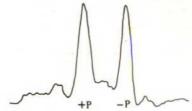

Fig. 5 a, Densitometer trace of a gel of an isoprenaline-relaxed muscle showing less than 5% phosphorylation of the LC20. b, Tension trace of a portal vein exposed to a high K+ depolarizing solution. The muscle was rapidly frozen at 6 s (arrow) by shooting a beaker of supercooled Freon 22 up to the muscle. c, Densitometer trace of the LC20 myosin light chains in an aliquot of the same, contracted muscle, showing that 50% of the LC20s are in the phosphorylated form. For the phosphorylation studies, the frozen muscles were pulverized with 0.5 M HClO4 at liquid N2 temperature. After thawing, the protein precipitate was dissolved in 9 M urea and 5% mercaptoethanol.

# Stress does not alter the conformation of a domain of the myosin cross-bridge in rigor muscle fibres

#### Roger Cooke

Department of Biochemistry and Biophysics and the Cardiovascular Research Institute, University of California, San Francisco, California 94143, USA

The force of muscle contraction is thought to be generated by a change in the effective angle of a myosin cross-bridge while it is attached to an actin filament. Thus studies of the relationship between this conformation and force provide insight into the mechanism of contraction. Recently it has been shown¹ that paramagnetic probes can be attached selectively and rigidly to a reactive sulphydryl on the myosin cross-bridge and that their angular distribution can be measured with great accuracy. In rigor skeletal fibres the probes are highly ordered relative to the fibre axis. Here I show that forces of up to 0.2 N mm⁻² cause no change in the angular distribution of the probes. Thus there is a domain of the cross-bridge whose conformation is not influenced by stress, and this result places restrictions on the location of elastic and force-generating elements within the cross-bridge.

The heads of the myosin molecule form bridges between the myosin and actin filaments. During contraction several changes in the conformation of these cross-bridges are thought to occur, including the stretching of an elastic element and a change in the configuration of some force-generating element resulting in a large (~45°) change in the effective angle of the cross-bridge<sup>2.3</sup>. The location of these elements within the cross-bridge is unknown; one possibility is that one or both may reside in the actin-myosin bond. By measuring the angle of one portion of myosin in a rigor fibre, that is, a fibre in the absence of ATP, we provide information on the location of these elements.

Various methods have been used to monitor the angle of the myosin heads in muscle fibres, including electron microscopy4, X-ray diffraction<sup>5</sup> and fluorescence spectroscopy<sup>6</sup>. Only two of these have been used to explore the relationship between force and cross-bridge orientation in rigor fibres. Naylor and Podolsky have shown that the intensity ratio of two equatorial reflections in the X-ray diffraction pattern did not change on application of a static strain, and dos Remedios et al. showed that the polarization of tryptophan fluorescence did not change when the rigor fibre was subjected to a periodic strain. For both these methods, the parameters observed reflected the conformation of the entire fibre, the X-ray being sensitive to the distribution of mass in the filament array and the fluorescence being derived from all tryptophans in the fibre. Thus, paramagnetic probes, which allow accurate and direct measurement of the angular conformation of one portion of the myosin molecule, provide quite different information from that obtained using these other methods.

Two probes were used having reactive groups that resembled iodoacetamide (IASL) and melaimide (MSL). Both labels have been shown to react selectively with a sulphydryl on the myosin head, designated  $SH_1$  (refs 2, 9). The hyperfine interaction between the unpaired electron and the nitrogen nucleus splits the spectrum of a nitroxide radical into three lines. Both the splitting between these lines and the g value depend on the angles between spin probe axes and the magnetic field of the spectrometer<sup>2,10</sup>. When the magnetic field is aligned along the fibre axis this effect allows measurement of the angle between this axis and the principle axis of the spin probe.

Figure 1 shows the spectra of fibres labelled with IASL. The fibres are in rigor at a sarcomere length of 2.2-2.4 µm where all the myosin heads are overlapped by thin filaments. These spectra are seen to consist essentially of three lines, indicating that most of the probes have the same approximate angle with respect to the fibre axis. It was shown previously<sup>2</sup> that such spectra are well described by assuming that the angular distribution of probes is gaussian, centred at 68° with a full width at half height of 15°. As shown in Fig. 1, a static stress applied to the fibres caused little alteration in their spectra. It was expected that stress would result in: (1) a shift in the average angle of the gaussian distribution: (2) a broader distribution and/or (3) that the cross-bridges would assume some new and radically different distribution. Any shift in the mean angle of the gaussian distribution would result in a shift in the splitting between the peaks. This splitting, indicated by arrows in Fig. 1, is shown in Fig. 2 for both labels as a function of the stress on the fibre. There was no change in the mean angle of either probe within

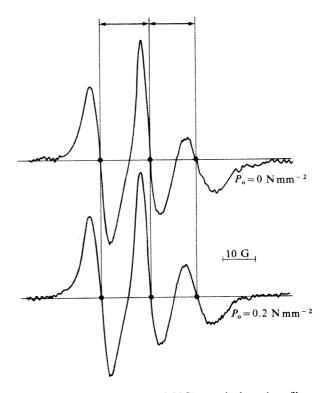

Fig. 1 Paramagnetic spectra of IASL attached to rigor fibres shown for two cases: above, tension = 0; below, tension =  $0.2 \text{ N mm}^{-2}$ . The fibres were labelled with 0.5 mM IASL for 1 h following procedures described elsewhere1. Several methods, including quantitation of peak heights in the spectrum and the decrease in the EDTA-ATPase of myosin extracted from the fibres, indicated that 70-100% of the myosin heads were labelled specifically on the reactive SH by this procedure. The rigor stiffness and the ability to generate isometric tension were both unchanged by labelling of the myosin heads. Spectra were obtained using a Varian E-3 spectrometer with a cavity modified to permit simultaneous recording of tension and spectra. This was accomplished by drilling holes (2 mm diameter) in the side faces of the cavity. A fibre bundle (6-10 fibres) was mounted in a capillary that was inserted through the cavity, so that the long axis of the bundle was aligned along the magnetic field of the spectrometer. One end of the fibre was secured by surgical silk to a solid-state tension transducer mounted on one side of the cavity. A force was exerted on the other end of the fibre using weights that were attached by a length of surgical silk. Each spectrum was acquired in 4 min, and during this time the fibre did not lengthen appreciably. The derivative of the absorption is plotted as a function of the magnetic field strength, thus the splitting between the three peaks is given by the distance between points where the spectrum crosses the base line, indicated by arrows above the spectra.

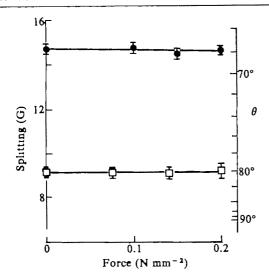

Fig. 2 The splitting between the lines in the electron paramagnetic resonance spectra, indicated by arrows in Fig. 1, is plotted as a function of the stress applied to the fibre. This splitting is a function of  $\theta$ , the mean angle of the angular distribution of the probes, shown on the right. •, Data from fibres labelled with IASL; , data from fibres labelled with MSL. Fibres were labelled with MSL using procedures outlined previously except that the concentration of K<sub>3</sub>Fe(CN)<sub>6</sub>, used to reduce nonspecific labels, was reduced to 25 mM. Each data point represents the mean of at least two separate measurements for each of two to four different fibres. Because of errors in the measurement of the cross-section of the fibre bundles, there is a 20% error in the tension measurements.

the experimental accuracy of the method (±1°) (Fig. 2). The width of the lines in Fig. 1 is related to the spread of the angular distribution. The experimental apparatus used here gave a sharp angular distribution with a full width at half height of  $\sim 12^{\circ}$ . The application of a stress to the fibres resulted in a slight sharpening of the lines, equivalent to further reducing the width of the gaussian distribution by  $\sim 2^{\circ}$ . This effect was found after a small stress was applied, and thus is probably due to better alignment of the fibres than in previous studies<sup>2</sup>. If some of the probes had changed to a new angle, additional intensity would be generated at new positions in the spectrum. No new intensity was seen and a careful comparison of spectra indicated that <10% of the probes changed angles from the gaussian distribution characteristic of rigor muscle.

Although the paramagnetic spectra allow the accurate measurement of the angle of the probe relative to the fibre axis, the relative orientation of the probe and the myosin head is not known with certainty. This uncertainty prompts the question, could the head rotate without probe rotation? Some information on the orientation of the probe relative to the head can be obtained from the measurement of the rotational relaxation time of probes bound to myosin subfragment 1 free in solution. These probes have a long relaxation time of ~200 ns, indicating that their axis lies along some long axis of subfragment 1 (ref. 11). As the myosin head is thought to be an elongated structure with an actin binding site at one end and the attachment to the thick filament at the other, any probe whose axis lies along the long axis of the head should be sensitive to rotations of the head induced by stress. In addition, two paramagnetic probes, linked to the SH<sub>1</sub> through structurally different groups and having axes at least 12° apart, gave the same result. Thus we conclude that the region of myosin surrounding the SH1 does not change orientation when a stress is applied to a rigor fibre. These results agree with those of others 7.8 who also concluded that the myosin head did not rotate on application of stress.

When a step change in length is applied to an isometrically contracting fibre, there is a complex transient in tension of the fibre<sup>3,12</sup>. The first portion of this transient, a sudden change in tension, is interpreted as arising from an elastic element that is in series with the element which generates force. Recent measurements of these transients at different sarcomere lengths have shown that this elasticity resides in the cross-bridge structure and thus may constitute an important part of the contractile apparatus<sup>12</sup>. Some theorists have placed this elastic element in the bond between actin and myosin11, in which case the application of a static stress would change the angle of the crossbridge. Thus our results show that this element cannot reside in the acto-myosin bond and it must lie somewhere between the SH, probe site and the thick filament. As the elastic element is a part of the cross-bridge it may be located in the S2 region which connects the head to the filament backbone, or it may result from some flexibility in the head.

٠,٠٠٠,٠

Present models of the contractile interaction envisage that force is produced by a myosin head attached to actin when the head rotates through an axial gradient of free energy. Whether the contractile element will shift its configuration on application of stress to rigor muscle depends on the shape of the free energy curve for the state in which no nucleotides are bound to myosin. If the configuration of the contractile element is confined in a deep well of free energy in this state then no change is expected. However, if it is confined by a shallower well, such as proposed by some theorists for other states<sup>13</sup>, it should change configuration. Therefore my results require that, unless the contractile element is very stiff in the rigor state, it must also lie between the probe site and the thick filament. This suggests that the actin-myosin bond is stiff and that it is not involved directly in the changes in cross-bridge conformation discussed above.

I conclude that there is a domain of the myosin head whose conformation is not influenced by force on the rigor fibre. As the SH<sub>1</sub> is in this domain, its position provides some estimate of the size of the domain. Although the exact location of the SH<sub>1</sub> is unknown, fluorescent energy transfer has provided some information on its relation to the actin binding site. The distance from SH<sub>1</sub> to Cys 373 of actin has been found to be  $\sim$ 6 nm (ref. 14). The cys 373 is 3.5 nm from the centre of the actin filament whose diameter is estimated to be 7-8 nm (ref. 15), and thus it cannot be very far from the actin-myosin binding site, also shown to be on the outer portion of the actin filament. If these distances are laid out on a three-dimensional model of the structure of the acto-S1 complex16, it appears unlikely that the SH<sub>1</sub> could be directly adjacent to the actin binding site, and thus the domain discussed above probably comprises a significant portion of the myosin head.

I thank Aron Yoffe and Laurence McCabe for assistance in completing the experiments, and Drs David Thomas, Michael Wilson, Robert Mendelson and Manuel Morales for their helpful discussions. This work was supported in part by grants from the USPHS, HL16683 and Research Career Development Award AM00479.

## Synthesis of an unspliced cytoplasmic message by an adenovirus 5 deletion mutant

Leon Carlock & Nicholas C. Jones\*

Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907, USA

Most genes in eukaryotic cells and their viruses contain non-coding intervening sequences (introns)<sup>1-5</sup>. These sequences are excised from each transcript during maturation of mRNA by a process known as RNA splicing. Although very little is known about the mechanism by which splicing occurs or its biological significance, several studies have suggested that the removal of introns is a necessary prerequisite to the accumulation of stable, cytoplasmic mRNA<sup>6-10</sup>. Here we describe a mutant of adenovirus 5 (Ad5) containing a deletion within early region Ela; the deletion prevents splicing of the normal Ela transcripts. The unspliced transcript is found in the cytoplasm of infected cells, showing that for this gene, splicing is not necessary for the biosynthesis of cytoplasmic message.

Region Ela is located at the extreme left-hand end of the adenovirus genome (1.5-4.5 map units). At early times of infection two overlapping mRNAs (a 12S and a 13S species) are produced by differential splicing of a common precursor 11.12. The two messages share 5' and 3' sequences but differ in the extent to which internal sequences are removed by RNA splicing (Fig. 1). The structure of the dl502 genome is also shown in Fig. 1. DNA sequence analysis identified a deletion of 330 base pairs fusing nucleotide 1,009 to nucleotide 1,340. The deletion thus removes the acceptor and one of the donor (D2) splice junctions together with flanking coding sequences.

Because the common acceptor splice junction is absent in dl502, it was anticipated that the primary transcript from this region would fail to undergo splicing. This was found to be the case. Cytoplasmic RNA isolated from wild-type and dl502infected HeLa cells was analysed by the S1 mapping procedure of Berk and Sharp<sup>13</sup> and as the results described in Fig. 2 clearly show, an unspliced Ela message is synthesized and accumulates in the cytoplasm of dl502-infected cells. As the hybridizations are performed with an excess of DNA probe, the intensity of autoradiograph bands is proportional to the abundance of the corresponding mRNA. Comparison of the Ela-generated bands from wild-type and dl502 RNA preparations indicates that the unspliced Ela product from dl502 accumulates in the cytoplasm to 25-50% of the levels of wild-type Ela products. The lower levels are probably due to a defective Ela gene product in dl502. Other mutants with altered Ela products show a similar decrease in the levels of Ela messages, possibly indicating that an Ela product regulates its own synthesis 14,15

We consider it very unlikely that the unspliced message detected could have resulted from nuclear leakage during fractionation of the RNA. The RNA was isolated using isotonic

RNA extraction conditions, where nuclear leakage is reported to be low 16,17. Furthermore, two phenotypic properties of dl 502 that we have studied indicated that a defective Ela gene product is being synthesized and is partially functional. The first property is the host-range phenotype of Dl502. Not unexpectedly, dl502 is defective for growth on HeLa cells. Region Ela encodes a product required for productive growth 18,19; mutants with alterations in this region, including dl502, are grown on 293 cells. These are Ad5-transformed human embryonic kidney cells<sup>20</sup>; they contain and express the left-hand end 11% of the Ad5 genome and consequently will complement mutants which have alterations in this region. Dl502 has a plaquing ratio on HeLa versus 293 cells of  $\sim 10^{-4}$ ; this is  $10^2 - 10^3$ -fold higher than the ratio obtained with another mutant, dl312, which contains a deletion removing almost the entire Ela region (data not shown and ref. 18). We attribute this difference to the synthesis of a partially functional Ela gene product by dl502, supporting our conclusion that a message from this region does accumulate in the cytoplasm of dl502-infected cells.

The second phenotypic property suggesting that a partially functional Ela product is being synthesized by dl502, is that transcripts from other regions of the genome are detected, although at reduced levels. A region Ela gene product is known to regulate the expression of other early regions of the genome, regions E1b, E2, E3 and E4<sup>21,22</sup>. Transcripts from these regions are not detected in dl312-infected cells unless very high MOIs are used<sup>15</sup>. However, as shown in Figs 2 (for region E1b) and 3 (for regions E2, E3 and E4), transcripts from all four of these regions are detected in the cytoplasm of HeLa cells infected with dl502 at relatively low MOIs ( $\sim$ 20 plaque-forming units (PFU) per cell). We again attribute this difference between dl502 and dl312 to the synthesis of a partially functional Ela gene product by dl502.

The major finding of the present study is that an unspliced region Ela transcript accumulates in the cytoplasm of dl502infected cells, showing that splicing and the removal of intron sequences are not necessary prerequisites to the production of stable, cytoplasmic RNA from this particular gene. The characterization of SV40 mutants containing deletions in both early and late genes has led to the conclusion that splicing is required not only for the removal of noncoding intron sequences but also in some unknown way for the stabilization and/or transport of message<sup>6-8</sup>. However, it is now known that several genes, including the gene for adenovirus protein IX<sup>23</sup> and a human interferon<sup>24</sup>, do not contain introns; the synthesis of message from these genes does not therefore require splicing. In addition, two other cases recently have been described where RNA splicing, although normally occurring during the synthesis of message from the genes examined, was found not to be obligatory to the synthesis of message from those genes<sup>25,26</sup>. A viable mutant of SV40, containing a small deletion in the leader region of the late genes, accumulated an unspliced 19S mRNA in the cytoplasm of infected cells25. Interestingly, other mutants containing alterations in different locations and which also prevented splicing of the 19S precursor RNA did not accumulate 19S message<sup>6</sup>, suggesting that the location of the deletion was critical in determining whether splicing was obligatory for

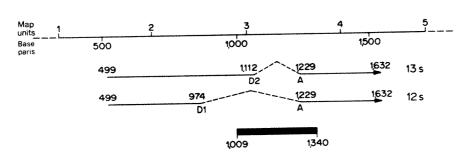

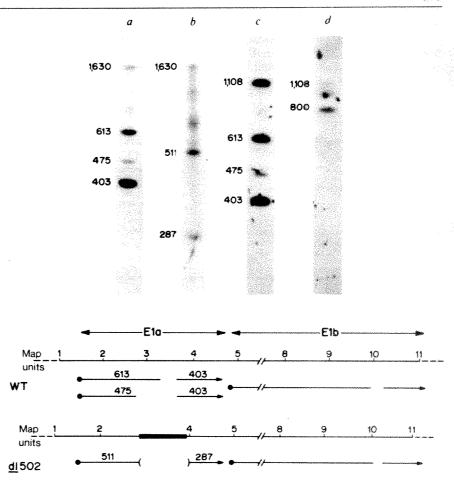

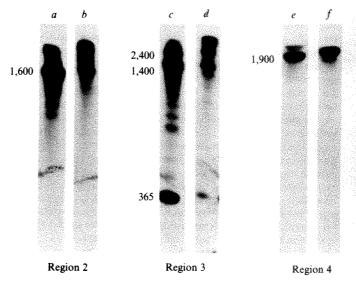

Fig. 1 Structure of the dl502 genome. The position of the deletion in dl502 is shown with respect to the two mRNA species produced from this region early after infection with Ad5<sup>11,12</sup>. The solid line indicates sequences present in the mRNA, caret symbols represent intervening sequences removed by RNA splicing and the arrows mark the position of the 3' end of the RNAs. The nucleotide positions of the splice junctions and 5' and 3' termini are from Perricaudet et al.<sup>27</sup>. D1 and D2 are the terms given to the two donor splice junctions and A is the acceptor junction. The deletion in dl502 as determined by DNA sequence analysis is indicated by the solid bar.

Fig. 2 S<sub>1</sub> analysis of cytoplasmic RNA from wild-type and dl502-infected cells. HeLa cells were infected with purified virions at a MOI of ~20 PFU per cell. Cytosine arabinoside was added 1 h later and the cells were collected 8 h post-infection. Cytoplasmic RNA was isolated from the infected cells by the isotonic extraction procedure described previously RNAs were analysed by the S1 mapping procedure essentially as described by Berk and Sharp<sup>13</sup>. <sup>32</sup>P-labelled DNA fragments (5 µg full genome equivalents per ml; specific activity  $2-4\times10^6$  c.p.m. per µg) were hybridized to total cytoplasmic RNA (5 mg ml<sup>-1</sup>) in 80% formamide, 0.4 M NaCl, 0.04 M PIPES pH 6.4, 0.001 M EDTA at 59 °C for 3 h. The hybridization mixture was then digested with S<sub>1</sub> endonuclease (40 units) in 200  $\mu$ l, 0.03 M NaOAc, 0.25 M NaCl, 0.001 M ZnCl<sub>2</sub>, 5% glycerol at 37 °C for 30 min. The digestion products were ethanol precipitated and electrophoresed on 3.8% polyacrylamide gels containing 8 M urea. a, RNA from wild-type infected cells hybridized to the BglII-D fragment (0-9 map units) isolated from wildtype DNA. Four major S<sub>1</sub>-resistant bands are detected. The band 1,630 nucleotides in length results from hybridization of region E1b mRNA (a region extending over 4.6-11.2 map units<sup>12</sup>) to the probe; the other three bands result from hybridization of E1a mRNA. b, RNA from dl502-infected cells hybridized to the same probe as that used in lane a. A 1,630nucleotide E1b band is seen together with two additional bands, 511 and 387 nucleotides long. These are the expected products if an unspliced RNA from region E1a was synthesized and hybridized to the probe; a deletion loop extending over 2.8-3.8 map units

would be present in the hybrid and be digested with the  $S_1$  endonuclease to give the two fragments seen. c, RNA from wild-type-infected cells hybridized to wild-type HindIII-G fragment (0-7.8 map units). The band resulting from the hybridization of E1b mRNA is smaller with this probe than the one used in lane a (1,108 nucleotides). d, RNA from dl502-infected cells hybridized to the dl502 HindIII-G fragment. As well as the band derived from E1b mRNA, a single additional band of  $\sim$ 800 nucleotides in length was detected which again is the size of the probe sequence that would be protected by an unspliced E1a mRNA. A diagram of region E1 and the mRNAs synthesized from this region by wild-type virus and dl502 is shown. The wild-type RNAs are described in detail in Fig. 1 legend.

Fig. 3 S<sub>1</sub> analysis of cytoplasmic RNA from wild-type and dl502 infected cells using probes specific for early regions 2, 3 and 4. The isolation of RNA and the S<sub>1</sub> mapping procedure are described in Fig. 2 legend. Lanes a, b, hybridization of RNA from wild-type (a) and dl502 (b) infected cells to the HindIII-A fragment (50.1-72.8 map uinits). A major product 1,600 nucleotides long is normally found. Lanes c, d, hybridization of wild-type (c) and dl502 (d) RNA to the HindIII-B fragment (72.8-89.1 map units). Three major products 2,400, 1,400 and 365 nucleotides in length are normally found. lanes e, f, hybridization of wild-type (e) and dl502 (f) RNA to the HindIII-F fragment (89.1-97.1 map units). A 1,900-nucleotide band is the major product. The largest bands detected in all the hybridizations are due to renaturation of the DNA probe; the renaturation is particularly evident in the hybridizations involving dl502 RNA.

message production. It is therefore possible that it is not splicing per se that is the critical factor in producing stable message but the presence or absence of certain important sequences in the precursor.

One possible model to explain all the results would be that a sequence(s) in the precursor RNA is necessary for the synthesis of mature cytoplasmic message (for example by mediating an interaction between the RNA and the nuclear membrane where the transport apparatus and possibly the splicing apparatus resides); if this sequence is missing maturation of the message

from the precursor could not occur. In genes that do not contain introns such a sequence would be located within coding regions. In genes that do contain introns the sequence could be in the intron, the exons or partially in both (perhaps spanning a splice junction). In examples where deletions prevented the accumulation of messages, the model would predict that the necessary sequences had been altered or removed. In examples such as d1502, however, where unspliced messages are found, the prediction would be that the sequence remained and was located within the coding sequences or the remaining portion of the

intron sequences. Implicit in the model is that splicing per se is not necessarily linked to the synthesis of cytoplasmic RNA. Nevertheless, in the normal situation unspliced precursors are confined to the nucleus. This would be the case if the rate of splicing far exceeded that of transport. This model would also be feasible if a particular feature of the secondary structure of the

The most common naturally occurring cancer of chickens associated with retrovirus infection is lymphoid leukosis (LL), a bursa (B) cell lymphoma. The primary causative agents are avian lymphoid leukosis viruses (LLVs), which do not necessarily have an oncogene. Recent evidence of Hayward et al. suggests that LLV infection promotes the expression of a cellular gene, c-myc (homologous to the oncogene of acute leukaemia virus, MC-29) thereby triggering the transformation process. In the majority of the tumours induced by LLV, the provirus is integrated next to the c-myc gene (refs 1, 3, 18, 19). To examine further the specific involvement of c-myc in lymphocytic transformation, we exploited our previous findings that replication-competent or non-defective reticuloendotheliosis virus (nd REV), genetically unrelated to LLV, are also capable of inducing lymphoma in chickens, with similar latent period and pathology to LL5. We have characterized the structure of the nd REV proviruses in the induced tumours and report here that proviral DNA is integrated next to c-myc in over 90% of the tumours analysed. This finding strengthens the hypothesis that the c-myc and its adjacent sequences are important in B-lymphocyte transformation. We also obtained evidence that amplification and structural alteration of the chromosomal region encompassing the REV provirus and cmyc gene have occurred during tumorigenesis in some of the tumours.

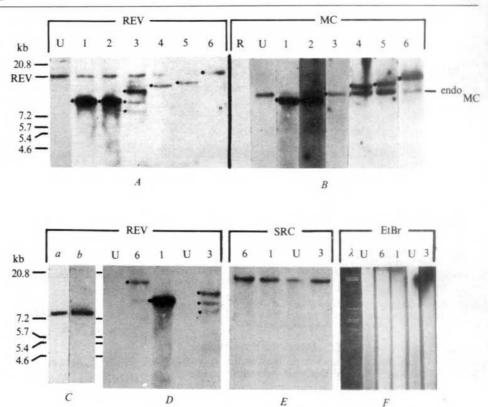

The DNAs extracted from bursal tumours induced by chick syncytial virus (CSV) strain of nd REV were digested with restriction endonucleases, electrophoresed in agarose gels and hybridized to probes specific for the nd REV genome (REVprobe) and the oncogene of MC-29 virus (MC-probe), respectively. The principal enzyme used in this study is EcoRI, which does not cleave the CSV DNA. As shown in Fig. 1C, lanes a and b, the unintegrated linear CSV DNA isolated from the acutely infected cells displays the same migration pattern before and after EcoRI digestion. Similarly, the unintegrated circular DNA can also be shown to lack EcoRI sites (data not shown). When EcoRI was used to cleave the high molecular weight DNA from the tissues (Fig. 1A), in all samples including the uninfected control (lane U), a band of about 18 kilobases (kb) is detected which presumably represents the endogenous REV sequence (endo<sub>REV</sub>). In the tumour sample (lanes 1-6), additional bands (indicated by dots) of differing sizes appear; these are referred to as tumour-specific (TS) bands. The TS band in lane 6, which has a mobility similar to that of endo<sub>REV</sub>, is difficult to discern in this experiment. The endogenous sequence, however, is only weakly hybridizable to the REV-probe (presumably due to the divergence of these two sequences) and it is possible to differentiate the endogenous and exogenous REV sequences by conducting the probe hybridization in more stringent conditions. As illustrated in Fig. 1D, in the more stringent conditions (45 °C) the hybridization to endo<sub>REV</sub> is reduced to the background level (see especially the uninfected control in lane U), whereas the intensity of the TS bands, inducing the 18-kb band of lane 6, are not affected. This analysis confirms the exogenous origin of all the TS bands.

To assess the linkage between REV proviruses and the c-myc gene, the EcoRI cleaved bursal DNAs were hybridized with the MC probe. As shown in Fig. 1B, the TS bands (indicated by dots) detected by the MC probe match the corresponding fragments identified by the REV probe in Fig. 1A. (The band, marked as endo<sub>MC</sub>, corresponds to the endogenous c-myc gene, which is present in both the normal and the tumour tissue<sup>3,6</sup>). Each tumour seems to have one TS band co-hybridizing to both probes. (In tumour no. 3, the TS band which joins the REV provirus and the c-myc gene co-migrates with the c-myc band. The linkage between REV provirus and c-myc gene are confirmed by digestion with other restriction enzymes.) Such cross-hybridizations are not due to homology between REV and MC sequences, as the unintegrated CSV DNA (lane R) is not detected by the MC probe. These results suggest that in each tumour, at least one REV provirus is integrated next to the c-myc gene (on one of the two homologous chromosomes) and strongly implicate the latter gene in lymphomagenesis.

The REV proviruses in 22 of the 25 tumours characterized are found to be linked to c-myc (Fig. 1 and unpublished data). The sizes of the EcoRI linkage fragments vary from 11 to 22 kb. The different sizes of TS bands suggest that integrations of the viral DNAs at several sites near the c-myc gene are conducive to transformation, a conclusion consistent with previous studies of the LLV-induced tumours<sup>1-4,18</sup>. A close examination of the TS band patterns, however, reveals that the size variation of some of these bands may also be caused by deletion or structural alteration of the cellular or viral sequences. If the TS bands result from a simple integrative recombination involving the

Fig. 1 The structure of REV proviruses and the c-myc gene in lymphoma as analysed using EcoRI digestion. Avian bursal lymphomas were induced by injections of end-point purified, helperindependent chicken cyncytial viruses (CSV; a member of the REV family) intra-abdominally into 1-day-old chicks of line 151, ×71. After a latent period of ~20 weeks, birds which developed lymphomas were killed and the tumour tissues collected<sup>5</sup>. Both the virus stock and the tumour samples were shown serologically and biochemically to be free of avian leukosis viruses. The DNAs were extracted from the tissues, digested with EcoRI, analysed by 0.8% agarose gel electrophoresis and transferred onto nitrocellulose filters, all as previously described15. Filter hybridizations were carried out in 50% formamide and 3× SSC (1×SSC = 0.15 M sodium chloride/0.015 M sodium citrate) at either 35 °C (panels A-C, E) or 45 °C (panel D). The radiolabelled hybridization probes were prepared by nick-trans-16 of the following three pBR322based DNA clones: a, pSNV-SalI 60B (a gift from H. Temin). This clone, which carries the entire genomic sequence (7.7 kb) of spleen necrosis virus (SNV)21 cloned in the SalI site of the pBR322 vector, was used to detect the REV sequence in tumour DNAs (the REV probe). SNV and CSV are genetically closely related and their genomes share ≥80% sequence homology (ref. 14 and M.R.N-D. and H-J.K., unpublished data).

b, pMC-Pst (a gift from D. Sheiness and J. M. Bishop). This clone, which principally carries the oncogene sequence of MC-29 virus<sup>22</sup>, was used to detect the c-myc gene (the MC probe). c, pSRC-pvuIIE (a gift from W. L. Delorbe and H. E. Varmus). This clone, which carries 0.8 kb of the oncogene sequence of Rous sarcoma virus<sup>23</sup>, was used to detect the cellular src gene in chicken chromosome (the src probe). Panels A, B, D, E, EcoRI-digested bursal DNA samples from an uninfected bird (lane U) or from tumorous birds (lanes 1-6). Panel E, the same filter as panel D, after removing the radioactive REV sequences by heating at 90 °C in TE buffer (5 mM Tris pH 6.5, 1 mM EDTA), were hybridized with the src probe as described above. Panel C, the linear, unintegrated CSV isolated from the cytoplasms of chicken embryo fibroblasts infected with the CSV viruses 48 h earlier by the procedures of Shank et al. 15. Lanes a and b represent DNA samples before or after EcoRI (Miles) digestion. All except panel F are autoradiograms of the filters after hybridization with the REV, MC or SRC probes (as indicated at the top of the gel). Panel F shows the ethidium bromide (Etbr)-stained DNA pattern of the gel used to prepare the filter shown in panels D and E. The molecular size markers (in kilobases, kb) shown on the side of the gels correspond to the migration pattern of the EcoRI-digested phage λ DNA (shown in lane λ of panel F), which was included in each gel run as an internal size standard.

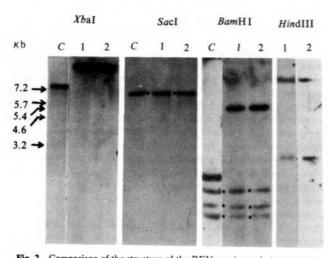

Fig. 2 Comparison of the structure of the REV proviruses in tumours no. 1 and no. 2. Chromosomal DNAs extracted from tumour no. 1 (lane 1), tumour 2 (lane 2) or the cytoplasmic unintegrated CSV DNA (lane C) were digested with restriction endonucleases (Biolabs and Biotech) as indicated at the top of the gels. The samples were analysed in 0.8% agarose gel and the Southern-filter hybridizations with the REV probe were conducted at 45 °C as described for Fig. 1D. Among the enzymes used here, XbaI has no cleavage site, HindIII has one cleavage site and Sac1 and BamHI have multiple cleavage sites in the CSV DNA (ref. 8 and R.A.S. and H-J.K., unpublished data).

REV DNA and the *c-myc* gene without other structural alterations, the *EcoRI-TS* band should have a size equal to the sum of the viral DNA and endo<sub>MC</sub> fragment. We found that this is not the case; especially obvious are samples 1 and 2 where the TS

bands are actually smaller than the c-myc fragment. This result indicates that a deletion or structural alteration (leading to the generation of a new EcoRI cleavage site) must have occurred. Further digestion analyses of the proviruses of samples 1 and 2 using other enzymes, including those which have multiple cleavage sites in viral DNA to generate the internal fragments (for example, SacI and BamHI), are shown in lanes 1 and 2 of Fig. 2. In all cases, identical patterns are displayed by these two proviruses, confirming the identity of the two proviruses. In addition, these proviruses seem to carry the major BamHI and SacI internal fragments (indicated by dots), comigrating with those generated from the cytoplasmic unintegrated viral DNA (Fig. 2, lane C). This indicates that the majority of viral sequences are present in these proviruses. Thus, the structural alterations which gave rise to the 'shortened' 11-kb TS band probably involve the surrounding cellular sequence.

The other interesting feature of the results shown in Fig. 1D is the unusual intensity of the hybridization signal of some of the TS bands, especially the 11-kb band in sample 1. The total amount of the chromosomal DNA loaded on each lane, as judged by the ethidium bromide stains, is comparable (Fig. 1F). Furthermore, when the same samples were hybridized with a cloned DNA carrying a portion of v-src (the transforming gene of Rous sarcoma virus), the intensity of the cellular src genes seem to be similar in all lanes. This confirms that the amount of chromosomal DNA of lane 1 is not appreciably different from that of other lanes. The high intensity of the 11-kb TS band in sample 1 is revealed by both REV and MC probes (Fig. 1A, B). This observation, together with the larger size of this band relative to the unintegrated viral DNA, suggests that amplification of the REV provirus and its surrounding cellular

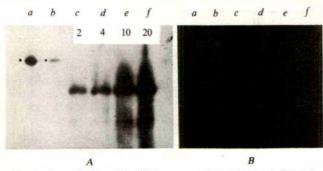

Fig. 3 Quantification of the CSV sequences in tumour no. 1. Panel A, 30 µg each of the EcoRI-digested chromosomal DNA from tumours no. 1 (lane a) and no. 8 (lane b) were analysed on a 0.8% agarose gel, then hybridized with the REV probe. The DNA concentration was determined by diphenylamine assay<sup>17</sup>. The cloned pSNV-Sal-60B DNA (lanes c-f) was used as a quantitation standard. The DNA insert which carries the 7.7-kb viral sequence was purified from the pBR322 vector by SalI cleavage and isolated from a preparative agarose gel. Lanes c, d, e and f contain 0.23, 0.46, 1.15 and 2.30 ng each of the purified SNV DNA insert. Based on a diploid genome size of 2×109 bases for chicken, these amounts of SNV DNA would give a 2, 4, 10 and 20 copies per cell equivalent of CSV sequences in 30 µg of chicken DNA. The weak, lower band in lanes c-f represents the contaminating pBR322 vector DNA. Panel B, the ethidium bromide-stained gel of panel A.

sequences have occurred. To obtain a further estimate of the amount of CSV sequences present in tumour no. 1, a titration experiment using the pSNV DNA (the plasmid clone used to make REV probe; see Fig. 1 legend) as quantitation standards was carried out (Fig. 3A). Thirty microgrammes each of tumours no. 1 (lane a) and no. 8 (lane b) DNA, digested with EcoRI, were loaded on an agorose gel together with varying amounts of the purified 7.7-kb insert of the pSNV DNA (lanes c-f). The quantities of the cloned DNA in lanes c-f were such that they represent, respectively, 2, 4, 10 and 20 copies per cell equivalent of CSV sequence in 30 µg of chicken DNA. We included tumour no. 8 DNA as a control, because it has an EcoRI-TS band similar in size to that of tumour no. 1, but has a usual, non-amplified intensity. (The ethidium bromide-stained gel is shown in Fig. 3B.) When the TS bands in lanes a and b were traced densitometrically and their intensity compared with that of the standards in lanes c-f, it was found that while tumour no. 8 acquired only one copy of the CSV provirus, tumour no. 1 appears to carry approximately eight copies of the proviral sequences.

The observation that the REV provirus and its adjacent cellular sequences may have undergone structural alteration in some of the tumours is intriguing in the light of the recent findings that retroviral DNA has a transposable-element-like structure<sup>8-12</sup> which behaves like prokaryotic transposable-elements in showing, for example, deletion formation and insertional mutagenesis 13,20. It is not clear how such structural alterations contribute to the transformation process, if indeed they do. Detailed structural analysis of the molecularly cloned TS bands should provide insight into the molecular mechanism of the recombination and their possible functions in transformation. Finally, the endogenous REV sequences detected in Fig. 1A merits discussion; such an EcoRI fragment has not previously been reported, although earlier liquid hybridization studies indicated a low level of homology (10-20%) between REV and the normal chicken chromosome<sup>14</sup>. We do not know whether this endogenous REV sequence is specific for the inbred line used here or is ubiquitous in chickens. We are now conducting restriction enzyme digestion analysis of the endo<sub>REV</sub> to determine the structural relationship between the endogenous and exogenous viral genomes.

We thank Drs J. M. Bishop, B. Delorbe, D. Sheiness, H. Temin and H. E. Varmus for providing the cloned DNAs for the syntheses of radioactive probes, Drs H. Temin, H. E. Varmus, M. Fluck, F. Rottman, E. Fritsch and E. J. Smith for critical reviews of the manuscript, and Ms S. Uselton for secretarial assistance. This work was supported in part by USPHS grant CA 2479-01, by NSF grant PCM-8021839 and by a grant from Michigan State University Foundation.

#### An isolated pseudogene related to the 5S RNA genes in Neurospora crassa

DNA segments which do not code for functional products but are similar in sequence to DNA of known function are called 'pseudogenes'. Most pseudogenes discovered so far are related to members of gene families: 5S RNA (5S) genes in Xenopus 1-3 globin genes in various mammals4-6, actin genes in Dictyostelium7 and small nuclear RNA genes in man8. Presumably, in the absence of strong selective forces, redundant genes drift apart and occasionally become nonfunctional. Of course, mechanisms which maintain homogeneity in multigene families should tend to prevent the occurrence of pseudogenes. There is ample evidence for 'horizontal' or 'concerted' evolution in tandemly repeated gene families<sup>9-11</sup>. The 5S pseudogenes of Xenopus laevis, of which there is a copy in every tandemly repeated unit, may be a rare example of a defective gene not eliminated from the family by unequal crossing-over or gene conversion events. We have recently found evidence for limited concerted evolution in a dispersed gene family, the 5S genes of Neurospora crassa 12: both identical and highly divergent 5S coding regions were discovered. We report here that we have found a pseudogene related to the Neurospora 5S genes. This pseudogene, N5SP1, contains a segment of DNA almost identical to the first 50 nucleotides of the major species of Neurospora 5S RNA. The sequences flanking this region are totally different from sequences found within or adjacent to full-length 5S genes. Hybridization experiments suggest that N5SP1 is not transcribed. The existence of this pseudogene is consistent with our transposition model for horizontal evolution in dispersed gene families12.

N5SP1 is contained on a plasmid designated pMF4. It was identified in a collection of Neurospora DNA fragments cloned into pBR322 (ref. 13) by colony hybridization 14 using labelled 5S RNA as probe. The first indication that pMF4 does not contain a complete 5S gene came from Southern 15 hybridization

<sup>‡</sup> Present addresses: Max-Planck-Institut für Zuchtungsforschung, D5000, Köln 30, FRG (E.U.S.); Department of Biological Sciences, State University of New York, Buffalo, New York 14260, USA (S.J.F.).

Hybridization of 5S RNA to restriction endonuclease digests of pMF4 DNA. a, Plasmid DNA (2 µg) was digested with KpnI and HpaI, together with Aval (lane 1). BamHI (lane 2), HaeII (lane 3), HaeIII (lane 4), HhaI (lane 5), HincII (lane 6), HpaII (lane 7), HinfI (lane 8), TaqI (lane 9), Tacl (lane 10), Sau3A (lane 11), or MboII (lane 12). The resulting DNA fragments were resolved on a 1.5% agarose gel in Tris-EDTA-acetate-NaCl buffer<sup>23</sup> and transferred to a nitrocellulose filter according to the method of Southern15. The filter was then hybridized with 32P-labelled 5S RNA $^{12}$  at 65 °C overnight in 5×SSC, 0.1% SDS. It was then washed extensively with 5×SSC, blot-dried and autoradiographed. The positions of size standards (in kilobase pairs, kbp) and of the origin (O) are indicated. HhaI (lane 5) and HincII (lane 6) did not cleave the KnpI-HpaI DNA fragment and the HaeII digestion (lane 3) did not go to completion. The DNA fragments which hybridized to 5S RNA in lanes 3 and 9 were too small to transfer effectively to nitrocellulose and therefore produced weak bands. b, Restriction map of KpnI-HpaI segment of pMF4 (data not shown) and interpretation of hybridization results. Solid horizontal lines indicate DNA fragments which hybridized to 5S RNA and broken lines indicate fragments which failed to hybridize. Fragments smaller than the TaqI-KpnI fragment did not transfer efficiently, and thus cannot be scored. Note that the Hpal-Tacl fragment hybridized well with 5S RNA, whereas the 19-nucleotide shorter HpaI-BamHI (or Sau3A) fragments did not hybridize at all. This is presumably because the BamHI cut is in the middle of the largest uninterrupted stretch of homology to 5S RNA.

experiments. Restriction digests of pMF4 DNA were fractionated by agarose gel electrophoresis, transferred to a nitrocellulose filter and hybridized with 32P-labelled 5S RNA. The results of this experiment showed that 5S RNA hybridizes to pMF4 DNA within a 550-base pair (bp) KpnI-HpaI fragment located near the middle of the 5,400-bp Neurospora DNA insert (data not shown). Surprisingly, digestion of pMF4 DNA with BamHI, which cleaves the KpnI-HpaI fragment, eliminates all subsequent hybridization with 5S RNA. Functional Neurospora 5S genes contain a BamHI site at nucleotide 32 in the coding region, but DNA cleaved at this site still hybridizes to 5S RNA 12. These findings suggest that a Bam HI site in pMF4 is in a region of incomplete 5S homology. The DNA segment homologous to 5S RNA was mapped by Southern hybridizations of pMF4 DNA digested with KpnI and HpaI together with other restriction endonucleases. The results (Fig. 1a) are consistent with the idea that the region of 5S homology is near the BamHI site (Fig. 1b). This region was sequenced as indicated in Fig. 2a and compared with sequences of two Neurospora 5S genes (Fig. 2b). As expected, the BamHI site is in a region homologous to 5S RNA. A ~ 50-nucleotide segment

corresponds to the first  $\sim 40\%$  of 5S RNA. With the exception of a three-nucleotide insertion, a single nucleotide insertion and two single nucleotide substitutions, this region matches the major 5S RNA sequence found in *Neurospora*. Outside this segment, there is no significant homology with DNA in or around the *Neurospora* 5S genes. *Neurospora* mitochondrial DNA does not hybridize to pMF4 (data not shown), ruling out the possibility that the cloned DNA encodes a mitochondrial RNA similar to cytoplasmic 5S RNA.

The Southern hybridization experiments and DNA sequence analysis suggests that pMF4 does not encode full-length 5S RNA. S<sub>1</sub> nuclease mapping <sup>16</sup> was performed to verify this (Fig. 3). pFM4 DNA 3'- or 5'-labelled at the Bam HI site in the region of 5S homology was hybridized with excess 5S RNA in R-looping <sup>17</sup> conditions. The single-stranded regions were digested with S<sub>1</sub> nuclease and the resulting hybrids denatured, fractionated on a denaturing polyacrylamide gel and autoradiographed. DNA fragments protected by RNA were detected on one side of the Bam HI site (corresponding to the 5' portion of 5S RNA) but not on the other, confirming that pMF4 does not encode a 5S RNA. For the authentic 5S clones pKD51 and pKD52, fragments corresponding to both the 5' and 3' portions were evident (Fig. 3).

To determine whether the presumptive pseudogene encodes RNA of a different size from 5S RNA, total *Neurospora* RNA fractioned on native (2.1% polyacrylamide, 0.5% agarose) or denaturing (7 M urea, 10% polyacrylamide) gels was transferred to diazobenzyloxymethyl paper 18,19, and probed with labelled pMF4 DNA. In each case, the only RNA species detected corresponded to 5S RNA, so it seems likely that the 5S-like DNA segment in pMF4 is a 5S pseudogene, which we designate N5SP1.

The sharp break in the sequence homology between N5SP1 and 5S RNA presumably reflects a DNA rearrangement which replaced the 3' portion of the ancestral 5S gene with foreign DNA. This substitution separated the 5' portion of the 5S gene from the central region which, at least in X. laevis 5S RNA genes<sup>20-22</sup>, is necessary for transcription initiation. A gene inactivated by such a rearrangement might be expected to accumulate subsequent mutations. The small insertions and point changes in N5SP1, relative to active 5S genes, presumably are examples of this. Other pseudogenes which have been discovered<sup>1-8</sup> also contain similar mutational changes.

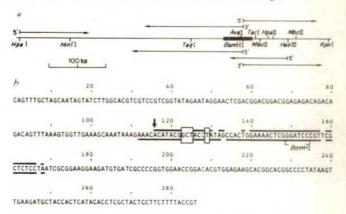

Fig. 2 DNA sequence of Neurospora 5S pseudogene, N5SP1. a, Restriction map with horizontal arrows illustrating sequencing runs on the two strands of DNA (above and below map). The lengths of the arrows indicate the extent to which the sequence could be read with confidence. DNA fragments were labelled at 5' termini by phosphorylation using  $[\gamma^{-32}P]$  ATP and T4 polynucleotide kinase<sup>21</sup> or at 3' termini by 'filling in' using  $[\alpha^{-32}P]$ dGTP and Escherichia coli DNA polymerase  $I^{24,25}$ . They were then sequenced according to the methods of Maxam and Gilbert<sup>26</sup>. Reaction products were resolved on 0.35-mm thick 20% or 8% polyacrylamide gels containing 7 M urea<sup>27</sup>. The heavy line indicates the region of homology to 5S RNA. b, DNA sequence of one strand in the vicinity of the BamH1 site in N5SP1. The horizontal lines above and below the sequence show the extent of homology with Neurospora β and α 5S genes on pKD51 and pKD52, respectively<sup>12</sup>. Boxes enclose two small insertions relative to the 5S genes. The arrow shows the presumed position of transcription initiation in the 5S genes.

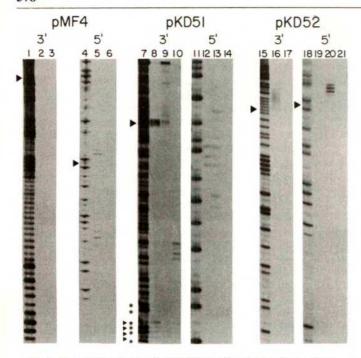

Fig. 3 S<sub>1</sub> nuclease mapping of 5S RNA homology to pseudogene clone pMF4 and authentic 5S clones pKD51 and pKD52. The BamHI ends of DNA fragments Kpnl-BamHI (lanes 1-3) and Pstl-BamHI (lanes 7-10 and 15-17) were labelled at their 3' ends (see Fig. 2). The BamHI ends of the fragments TaqI-BamHI were labelled at their 5' ends (lanes 4-6, 11-14 and 18-21). The labelled DNA was then used for the G>A DNA sequencing reaction 26 (lanes 1, 4, 11, 15, 18) or the A>C reaction (lane 7), or hybridized in R-looping conditions (10 µl containing 0.4 M NaCl, 0.04 M PIPES pH 6.4, 1 mM EDTA and deionized 80% formamide; 55 °C for the 5' fragments and 65 °C for the 3' fragments), with (lanes 2, 5, 8, 9, 12, 13, 16, 19, 20) or without (lanes 3, 6, 10, 14, 17, 21) a  $\sim$ 100-fold excess (0.1  $\mu$ g) of 5S RNA. After 16 h, the samples were chilled, diluted 10-fold in 0.25 M NaCl, 0.03 M sodium acetate pH 4.6 and 100 µg ml-1 denaturated salmon sperm DNA, and treated with  $S_1$  nuclease (Boehringer) at  $1~U~\mu l^{-1}$  (lanes 2, 3, 5, 6, 8, 10, 13, 14, 17, 20, 21) or  $10~U~\mu l^{-1}$  (lanes 9, 12, 16, 19) at  $22~^{\circ}$ C for 20~min. Finally, the nucleic acids were ethanol-precipitated, rinsed with 70% ethanol, dried and resuspended in 5-10 µl deionized 99% formamide containing xylene cyanol and bromophenol blue and fractionated on 8% or 20% polyacrylamide sequencing gels<sup>27</sup> next to the same DNA which had undergone partial cleavage in a DNA sequencing reaction. Large arrowheads indicate the expected migration of the fragments from the BamHI site to 3' or 5' ends of the 5S coding regions of pKD51 and pKD52. Small arrowheads mark the positions of faint bands in lane 8 where bulk 5S RNA fails to protect completely pKD51. This is near a region (\*) of recognized12 non-identity between pKD51 and pKD52.

If a defective 5S gene such as N5SP1 were part of a tandemly repeated multigene family, it could be eliminated by unequal crossing-over. Alternatively, it could be passively amplified as apparently occurred in the case of the Xenopus laevis 5S pseudogene 1,2. In dispersed gene families, defective members cannot be lost by unequal crossing-over. However, there is evidence for limited concerted evolution among the dispersed Neurospora 5S genes<sup>12</sup>. We pointed out that gene conversion or gene transposition, together with normal recombination processes, should have a homogenizing effect in a family of dispersed, repeated genes12. A feature of our model for concerted evolution by conservative transposition is that genes which fail to jump are immune to the homogenizing mechanism. The Neurospora 5S pseudogene may be an example of a defective gene which no longer participates in concerted evolution. Presumably it will continue to drift until it either becomes functional in some new way, or is deleted.

#### Identification of the Escherichia coli recB and recC gene products

#### Ian D. Hickson & Peter T. Emmerson

Department of Biochemistry, The University, Newcastle upon Tyne NE1 7RU, UK

Functional recB and recC genes are required for normal conjugative genetic recombination in Escherichia coli<sup>1-3</sup> mutations in either of these genes lead to deficiency in an ATP-dependent nuclease known as the RecBC DNase or exonuclease V (refs 4-6). Widely different molecular weights have been reported for the putative subunits of this enzyme<sup>7,8</sup> and genetic and biochemical experiments have left some doubt about whether or not recB and recC are different genes. We have now cloned the recB and recC genes separately into the multiple copy number plasmid pAT153 and identified the gene products by transposon inactivation and gel electrophoresis. The products of the recB and recC genes are proteins of molecular weights (MW) 135,000 and 125,000, respectively.

Mutations in either the recB or recC genes lead to apparently identical deficiency in genetic recombination, increased radiation sensitivity and decreased post-irradiation DNA degradation1,2. The recB and recC mutations cannot be distinguished phenotypically but have been assigned to different genes on the basis of genetic complementation tests and co-transduction frequencies with the neighbouring argA and thyA genes3. However, complex complementation behaviour has been observed among several recombination deficient mutations in this region (Hoekstra et al. cited in ref. 9) and the possibility that the observed complementation between recB and recC mutations may be intragenic cannot be discounted. In vitro complementation studies have also been difficult to interpret. The RecBC enzyme has been partially purified and dissociated by high salt concentrations into two subunits of MW 60,000 and 170,000, as determined by sedimentation in glycerol gradients<sup>7</sup>. It was found that the 170,000-MW protein would complement extracts from both recB and recC mutant strains whereas the 60,000-MW protein complemented neither7. These results suggest that the 170,000-MW protein is either a single polypeptide encoded by one gene of which recB and recC are mutations, or that it is made up of two polypeptides encoded by recB and recC which are not dissociated by high salt concentrations. However, in other work8, the enzyme has been purified to about 90% homogeneity and preparations were found, by SDS-polyacrylamide gel electrophoresis, to consist mainly of two protein subunits of 128,000 and 140,000 MW.

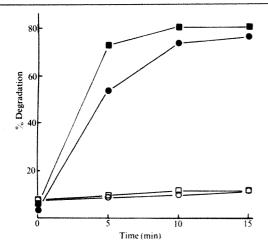

Fig. 1 ATP-dependent DNase activity in cell extracts. ○, AB2470 (recB); ♠, AB2470 (recB) harbouring pPE230 (recB<sup>+</sup>); □, AB3058 (recC); ■, AB3058 (recC) harbouring pPE220 (recC<sup>+</sup>). Cell lysates were assayed<sup>24</sup> for ability to degrade <sup>3</sup>H-labelled phage λ DNA to trichloroacetic acid-soluble material in the presence of ATP. Less than 10% degradation occurred in extracts of all four strains in the absence of ATP. Results with the strain AB1157 (rec<sup>+</sup>) were similar to those with AB2470 (pPE230) (data not shown).

In work to be published elsewhere, we first cloned a BamHI fragment of chromosomal DNA which included recC<sup>+</sup> into a phage λ vector to produce a recombinant phage λdrecC which was then used to derive the phage λdrecBC by secondary site integration at recC followed by aberrant excision (I.D.H., K. E. Atkinson and P.T.E., in preparation). We then subcloned the recB and recC genes from this phage DNA separately into the BamHI site of the plasmid vector pAT153 (Apr, Tcr) and transformed AB2470 (recB21) and AB3058 (recC22). Colonies resistant to both ampicillin and mitomycin C were selected and screened for those that were sensitive to tetracycline and resistant to UV light. The plasmids pPE230 (recB) and pPE220 (recC), obtained in this way, when transformed into AB2470 and AB3058, restored wild-type levels of RecBC

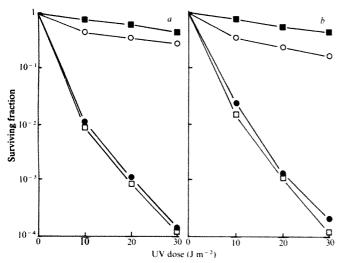

Fig. 2 UV-survival curves showing complementation of the recB mutation by pPE230 (recB<sup>+</sup>) and the recC mutation by pPE220 (recC<sup>+</sup>). a, ○, AB3058 (recC22) harbouring pPE220 (recB<sup>+</sup>); □, AB3058 (recC22) harbouring pPE230 (recB<sup>+</sup>); □, AB3058 (recC22) harbouring pAT153; ■, AB1157 (rec<sup>+</sup>) harbouring pAT153. b, ○, AB2470 (recB21) harbouring pPE230 (recC<sup>+</sup>); □, AB2470 (recB21) harbouring pPE220 (recC<sup>+</sup>); □, AB2470 (recB21) harbouring pAT153; ■, AB1157 (rec<sup>+</sup>) harbouring pAT153. The bacteria were grown to mid-exponential phase, collected, serially diluted in buffer, spread on nutrient agar plates, irradiated with a low-pressure mercury germicidal lamp and incubated overnight at 30 °C.

enzyme activity (Fig. 1) and UV resistance (Fig. 2). Restriction maps of these plasmids are shown in Fig. 3.

To identify the products of the recB and recC genes, we inserted the  $\gamma\delta$  (ref. 10) sequence of the sex factor F from Flac into the genes and examined extracts of 'maxicells' for altered proteins 11,12. The strain NH4104 (F'lac, Str\*) harbouring either pPE220 or pPE230 was mated with AB3058 (recC22) or AB2470 (recB21), respectively, and ampicillin-resistant, streptomycin-resistant exconjugants were selected. This selection is for plasmids (which carry Apr) transferred on conjugation because they have acquired  $\gamma\delta$  insertions from the F DNA. Colonies were then picked and screened for those which were UV-sensitive because the inserted transposable element had inactivated the recB or recC gene on the plasmid, which was therefore no longer able to complement the chromosomal mutation. Plasmid DNA was isolated<sup>13</sup> to confirm that the νδ sequence was inserted into the original plasmid, as manifested by an increase in size.

The proteins encoded by pPE220 and pPE230 were examined by subjecting labelled 'maxicell' extracts to SDS-polyacrylamide gel electrophoresis and fluorography. The results (Fig. 4) show that the plasmid pPE220 (recC) encodes a polypeptide of MW 125,000 (track 6) that is missing in plasmids in which the recC gene is inactivated by  $\gamma\delta$  (tracks 8–10). This polypeptide is present in a plasmid which carries a  $\gamma\delta$  insert in a gene other than recC (track 7). Similarly, the plasmid pPE230

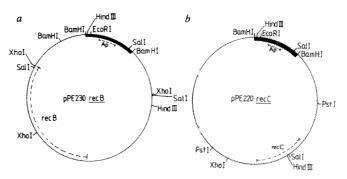

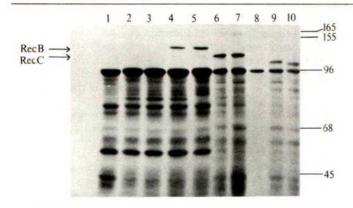

Fig. 3 Restriction maps of the recombinant plasmids. a, pPE230 (recB); b, pPE220 (recC). Vector DNA is drawn with a bold line. The inserts are  $\sim 17.5$  and 21.5 kilobases in pPE230 and pPE220, respectively. Restriction analysis of the plasmids and of their derivatives in which  $\gamma\delta$  is inserted into the recB and recC genes shows that these genes are located within the regions indicated.

(recB) encodes a polypeptide of MW 135,000 (track 5) that is absent in plasmids in which  $\gamma\delta$  is inserted into the recB gene (tracks 1-3), but present in a plasmid in which it is inserted at a site other than the recB gene (track 4). Insertion of  $\gamma\delta$  into a gene results in termination of transcription in five out of the six possible reading frames <sup>12,14</sup>, giving rise to truncated peptides. Truncated peptides can be seen in tracks 9 (115,000 MW) and 10 (108,000 MW). Proteins of MWs 125,000 and 135,000 are also synthesized in heavily UV-irradiated host cells infected with λdrecBC while a protein of MW 125,000 but not one of 135,000 is synthesized in similar experiments with the phage λdrecC which lacks recB (I.D.H., K. E. Atkinson and P.T.E., in preparation).

We conclude that the  $recB^+$  gene product is a protein of MW 135,000, the  $recC^+$  gene product is a protein of 125,000, and that recB and recC are different genes. Further evidence that these are different genes is provided by restriction analysis (Fig. 3), which fails to reveal any similarities between the restriction patterns of the inserts, and the complementation analysis (Fig. 2), which shows that there is a very sharp distinction between the abilities of pPE230 (recB) and pPE220 (recC) to complement recB and recC mutations. Our results do not support the conclusion that the recB and recC genes are both required to produce one of the subunits of the RecBC enzyme, but suggest that the two peptides of MWs 140,000 and 128,000 found in

<sup>35</sup>S-methionine labelled proteins produced in maxicells by the plasmids pPE230 (recB+) and pPE220 (recC+) and their derivatives in which  $\gamma\delta$  is inserted in the recB or recC gene  $(\gamma\delta 1-3)$ or in a gene other than recB or  $recC(\gamma\delta 0)$ , Tracks: 1, pPE230- $\gamma\delta 3$ ; 2, pPE230-γδ2; 3, pPE230-γδ1; 4, pPE230-γδ0 (recB<sup>+</sup>); 5, pPE230 (recB<sup>+</sup>); 6, pPE220 (recC<sup>+</sup>); 7, pPE220-γδ0 (recC<sup>+</sup>); 8, pPE220-γδ1; 9, pPE220-γδ2; 10, pPE220-γδ3. Proteins were separated by electrophoresis on an 8% polyacrylamide gel and visualized by fluorography. Molecular weights, determined by reference to unlabelled protein standards followed by staining, are indicated. The standards were RNA polymerase  $\beta'$  (165,000), RNA polymerase  $\beta$  (155,000), phosphorylase b (96,000), bovine serum albumin (68,000) and ovalbumin (45,000).

preparations of the RecBC enzyme that were 90% pure were the recB and recC products, respectively.

Our cloning of the recB and recC genes individually into a multicopy plasmid may lead to an easier method of isolating the individual subunits of the RecBC enzyme and should permit investigation of their partial properties. Our results do not rule out the possibility that active RecBC DNase includes one or more subunit(s) encoded by a gene or genes other than recB and recC. However, purification of the individual RecB and RecC subunits will permit studies of the reconstituted enzyme to help answer this question. Recent results show that at physiological ATP concentrations and in the presence of Ca<sup>2+</sup> the RecBC DNase uses energy derived from ATP hydrolysis to travel through duplex DNA, unwinding the DNA ahead of itself and rewinding it behind 15-17. In this regard, the RecBC DNase resembles other enzymes such as the helicases, gyrase and RecA protein which use the energy derived from ATP hydrolysis to modify the physical structure of DNA. Cloning of the recA gene 18-20 and the resultant ease with which the RecA protein could be isolated paved the way for the biochemical experiments which have greatly helped to explain the role of the RecA protein in genetic recombination and DNA repair<sup>21-23</sup>. The cloned recB and recC genes may also facilitate the isolation of the RecBC DNase and stimulate further experiments to determine its role in the cell.

#### Sexual activity reduces lifespan of male fruitflies

#### Linda Partridge & Marion Farquhar

Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh EH9 3JT, UK

Many theories on the evolution of life histories have assumed a physiological cost of reproduction in terms of reduced lifespan 1-3. A cost of increased reproduction in terms of reduced longevity has been established experimentally for females, both as an additive genetic<sup>4,5</sup> and as a purely phenotypic<sup>6,7</sup> effect. Such a physiological cost of reproduction has not been demonstrated for males. The cost of sexual activity has been assumed to be relatively small in those species where the only paternal contribution to an offspring is the gamete8.9. Here we show that increasing sexual activity reduces longevity in the male fruitfly (Drosophila melanogaster) and hence that there is a significant physiological cost of male sexual activity in a species where the father contributes only gametes to his progeny.

The flies used were an outbred stock collected in Dahomey in 1970. Sexual activity was manipulated by supplying individual males with receptive virgin females at a rate of one or eight virgins per day. The longevity of these males was recorded and compared with that of two control types. The first control consisted of two sets of individual males kept with newly inseminated females equal in number to the virgin females supplied to the experimental males. Newly inseminated females will not usually re-mate for at least 2 days 10,11 thus they served as a control for any effect of competition with the male for food or space. The second control was a set of individual males kept with no females. There were 25 males in each of the experimental and control groups, and the groups were treated identically in respect of number of anaesthetizations (using CO2) and provision of fresh food medium.

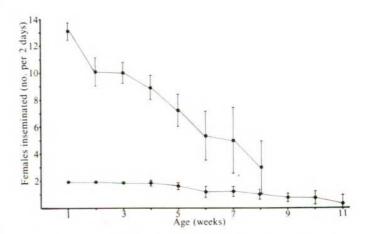

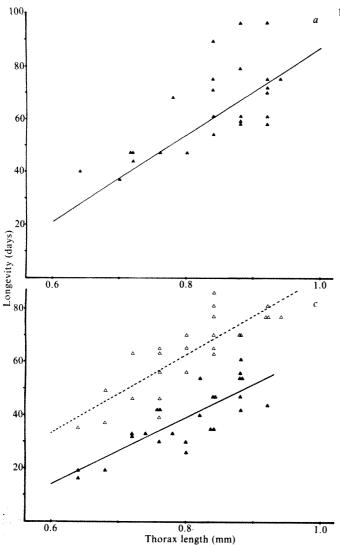

Fig. 1 The relationship between insemination rate (number of females inseminated per 2 days) and age (weeks) for males kept with one virgin female ( ) or eight virgin females ( ) per day. Error bars are 95% confidence limits.

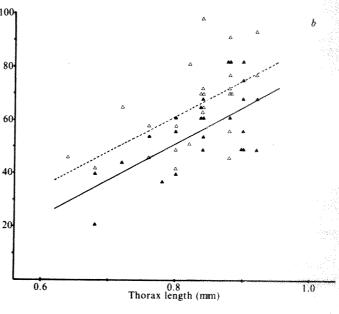

Fig. 2 The relationship between longevity and size for a, males kept with no females; b, males kept with one virgin (A one inseminated (△- $--\triangle$ ) female per day; c, males kept with eight virgin (▲- $-\triangle$ ) or eight inseminated  $(\triangle - - - - \triangle)$  females per day. The lines show the regression of longevity on thorax length, which is statistically significant (P < 0.01) in each case. Analysis of covariance showed that none of the control groups (no females, or one or eight inseminated females per day) differed significantly from one another in longewity. Males kept with one virgin female per day had reduced longevity compared with males kept with no females (P < 0.05) or one inseminated (P < 0.01)female per day; those kept with eight virgin females per day had reduced longevity compared with males kept with no females (P < 0.001), eight inseminated females (P < 0.001) or one virgin female (P < 0.001) per day.

On two days per week throughout the life of each experimental male, the females that had been supplied as virgins to that male were kept and examined for fertile eggs. This gave an estimate of the insemination rate of the two groups of males (Fig. 1). In both groups the insemination rate declined with the age of the male, and the rate was higher for males supplied with eight virgins per day than for those supplied with only one virgin per day. There were no significant differences in insemination rate between the individual males within each experimental group.

In the absence of any sexual activity, the longevity of male fruitflies is associated with their size (Fig. 2a). Size was therefore taken into account when examining the effect of sexual activity on longevity (Fig. 2b, c). Analysis of covariance showed that: (1) there were no significant differences in longevity between the control groups (median longevity 65 days); (2) the males supplied with one virgin female per day had significantly reduced longevity (median 56 days) compared with males in any control group; (3) males kept with eight virgin females per day had significantly reduced longevity (median 40 days) compared with males kept with one virgin female per day, and control males. These results show that male sexual activity reduces longevity, and that this effect is more marked for a higher level of sexual activity.

Physiological costs of particular activities have generally been discussed in terms of the diversion of nutrients into these activities at the expense of others<sup>12</sup>. In our experiment, energetic costs of sexual activity would have included the production of sperm and seminal fluid and the muscular action associated with mating itself. In addition to inseminating females, the

experimental males probably also performed higher levels of courtship than control males. The control males kept without females performed no courtship. When inseminated females are courted they extrude the ovipositor, which terminates the male courtship<sup>13</sup>. In nature, nutritional effects may be increased by food shortage, and there may be costs of sexual activity in addition to those detected here. Searching for mates<sup>14</sup> and fighting with other males<sup>15</sup> may be costly physiologically and these activities, together with courtship and mating, may make males more vulnerable to predation<sup>16</sup>.

Sexual activity could affect longevity in two ways. First, it may have an effect on the probability of death occurring in the next short period of time. Cessation of sexual activity at any age would then leave a fly with a life expectancy comparable with that of controls of the same age. High temperatures can have such an effect on longevity in *Drosophila subobscura* 17. Second, sexual activity may have some cumulative, possibly irreversible, effect. Williams 18 has suggested that senescence may be caused by the deleterious pleiotropic effects later in life of genes which have beneficial effects early in life. A deleterious long-term effect of sexual activity earlier in life could produce such a pleiotropic effect. Phenotypic correlations of the kind found in these experiments need not necessarily mean that a genetically caused change in the level of male sexual activity would alter longevity. A negative additive genetic correlation would be needed to demonstrate this and should be the subject of further experiments.

#### Pulmonary vein as an ectopic focus in digitalis-induced arrhythmia

D. W. Cheung\*

Department of Physiology, Monash University, Clayton, Victoria 3168, Australia

The tunica media of the pulmonary vein (PV) in many mammalian species, including man, is made up of cardiac muscle<sup>1</sup> Brunton and Fayrer first reported that independent pulsation of the PV occurred in cats and rabbits even after activity of the heart had ceased4. Electrophysiological studies have also shown spontaneous electrical activity in isolated PVs of the guinea pig and a pacemaking region has been located at the distal end of the cardiac portion of the vein adjoining the smooth muscle. The intrinsic frequency of the PV was low and activity at the PV was normally coupled to the sinus rhythm<sup>5</sup>. Thus, the PV behaves as a subsidiary pacemaker. In the presence of digitalis-type agents, subsidiary pacemakers such as Purkinje fibres develop oscillatory afterpotentials (OAPs) which may be large enough to reach threshold<sup>6,7</sup>, and it has been suggested that OAPs at Purkinje fibres leading to spontaneous action potentials may provide the underlying mechanism for ventricular arrhythmia during digitalis intoxication<sup>6</sup>. In contrast, atrial and ventricular muscles are not very sensitive to the arrhythmogenic action of digitalis8. I have therefore now investigated whether the PV can develop OAPs and act as an ectopic focus with digitalis intoxication. By recording with intracellular microelectrodes simultaneously at the PV and right atrium, I demonstrate that OAPs and repetitive activity develop at the PV in the presence of ouabain. Propagation of these triggered action potentials at the PV into the atrium results in atrial extrasystoles.

The recording arrangements in these experiments were similar to those reported previously<sup>5</sup>. Using male guinea pigs (300-400 g), intracellular recordings were made with glass micropipettes filled with 3 M KCl. All recordings were made at the distal end of the cardiac PV and the dorsal surface of the intact right atrium close to the vena cava. The experiments were carried out at 32-34 °C, the preparations being superfused continuously with normal or ouabain-containing physiological solutions at a rate of 4 ml min<sup>-1</sup>.

In spontaneously active preparations, the PV was driven by impulses originating from the SA node<sup>5</sup>. In the presence of ouabain (0.5–1.0  $\mu M$ ), the sinus rate decreased and became less regular, and in all seven preparations studied, after 30-40 min OAPs developed at the PV but not in atrial muscle cells (Fig. 1). Diastolic potentials between action potentials remained flat at the atrial recording site.

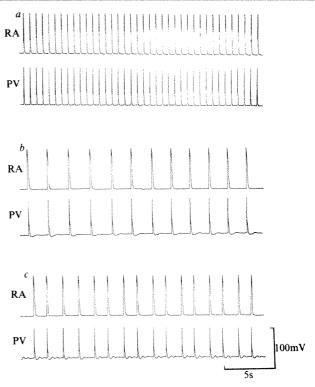

Fig. 1 Effect of ouabain  $(0.5 \mu M)$  on the electrical activity of the pulmonary vein (PV) and the right atrium (RA). As demonstrated previously, action potentials at the PV are closely coupled to those at the RA5. After exposure to ouabain for 40 min, OAPs developed at the PV (b) and became very prominent at 50 min (c). No membrane oscillation was observed at the RA. The spontaneous frequency of the preparation decreased in the presence of ouabain.

When higher ouabain concentrations were used ( $\geq 2 \mu M$ ), high frequency repetitive activity appeared in six out of six preparations. Figure 2 demonstrates the onset of repetitive activity in a preparation after exposure to ouabain (2.5 µM) for 75 min. Initially, two short bursts of extrasystoles were observed (Fig. 2a), soon followed by a period of repetitive activity lasting for about  $2\frac{1}{2}$  min at both the PV and the right atrium. Another train of repetitive activity followed after a brief pause (Fig. 2b).

Closer examination of the record revealed that the extrasystoles were of PV origin triggered by the sinus beats. In normal conditions, action potentials at the right atrium always preceded those at the PV<sup>5</sup>. The first pair of action potentials of each train of repetitive activity was also led by the atrial muscle, indicating the sinus origin of these action potentials. However, the lead was shifted to the PV in all subsequent action potentials of the train, suggesting the diversion of the pacemaking site to a region close to the PV (Fig. 2c). These action potentials at the PV were characterized by large diastolic depolarizations. In contrast, action potentials at the right atrium arose abruptly from the baseline membrane potential. Subthreshold OAPs were observed at the PV but not at atrial sites after termination of each train. Figure 2d also demonstrates the initiation of a second train of repetitive activity triggered by the sinus beat and the subsequent shift of pacemaking site to the PV.

The amplitude of action potentials at the PV decreased gradually with time in ouabain. This decrease was more marked during repetitive activity. For example, the amplitude of action potentials decreased by about 30 mV at the end of the long train in Fig. 2b and remained small subsequently. There was also a slight decrement in the amplitude of action potentials at the right atrium during repetitive activity.

The duration of each period of repetitive activity decreased drastically within 10 to 20 min after their appearance. For example, 5 min after the long train shown in Fig. 2b, only three action potentials appeared in each train (Fig. 3a). This further

<sup>\*</sup>Fresent address: Department of Pharmacology, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

decreased to two action potentials after a further  $2 \min (\text{Fig. } 3b)$ , and  $4 \min |\text{later}$ , no extrasystoles were observed (Fig. 3c).

To demonstrate that extrasystoles originated at the PV and required a triggering input, the PV was stimulated electrically using a pair of platinum wire electrodes placed close to the recording site. It was found that repetitive activity could also be initiated with electrical stimulation (Figs 3b, 4). Figure 3b demonstrates a coupled beat in response to a single stimulus at the PV. This response was similar to those occurring spontaneously except the phase lead of both the first and second pair of action potentials were now at the PV.

Conduction block between the PV and the right atrium developed in four out of seven preparations in the presence of ouabain. Figure 4a shows an example of unidirectional block with triggered activity at the PV coupled to the sinus beats. Repetitive activity at the PV did not affect atrial activity. A more severe block is demonstrated in Fig. 4b, in which the PV was quiescent and uncoupled to atrial activity. A strong electrical pulse applied at the PV proximal to the heart elicited an action potential in the atrium and at the same time triggered repetitive activity at the PV. After severing the PV from the heart, repetitive activity could still be triggered at the PV with electrical stimulation (Fig. 4c).

I have demonstrated here that the PV can act as an ectopic focus in atrial arrhythmia with digitalis intoxication. Thus, similar to Purkinje fibres, OAPs and repetitive activity developed at the PV in the presence of ouabain, the duration of repetitive activity decreasing with time of exposure to ouabain.

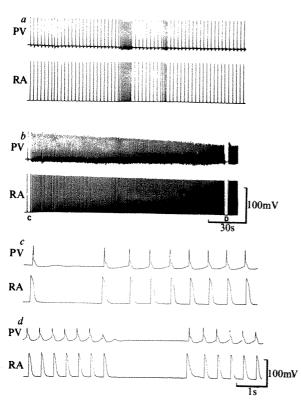

Fig. 2 Effect of a high concentration of ouabain  $(2.5 \,\mu\text{M})$  on the spontaneous activity of an atrium-PV preparation. After 75 min in ouabain, OAPs at the PV reached threshold. Initially, only two brief bursts were observed (a), but was followed soon after by a long train of repetitive response lasting for  $2\frac{1}{2}\min(b)$ . The first pair of action potentials of the train was characterized by the action potential at the RA preceding that of the PV (c). The phase lead then shifted to the PV in all subsequent action potentials of the train. These triggered action potentials were associated with pacemaking potentials at the PV. Subthreshold OAPs were observed at the PV following termination of each train (d). d Also shows the initiation of a second train by a sinus beat and the subsequent shift in phase lead to the PV. There was also a dramatic reduction in the amplitude of action potentials at the PV with repetitive activity (b).

The amplitude of action potentials of the PV also decreased dramatically with repetitive activity although the membrane potential did not alter significantly. A possible cause for the decrease in amplitude of action potentials and OAPs with prolonged exposure to ouabain is the accumulation of intracellular sodium. High intracellular sodium would shift the sodium

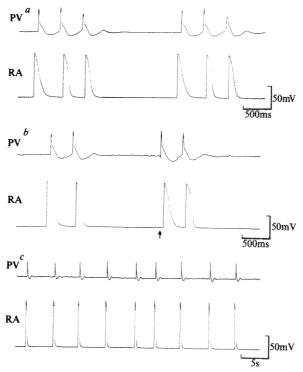

Fig. 3 The duration of repetitive activity decreased with prolonged exposure to ouabain. a Was recorded 5 min after the long train in Fig. 2b and b was recorded another 2 min later. Extrasystoles were not observed with further exposure to ouabain c. In b, an electrical stimulus (arrow) was applied close to the recording electrode at the PV to produce a coupled response similar to that occurring spontaneously.

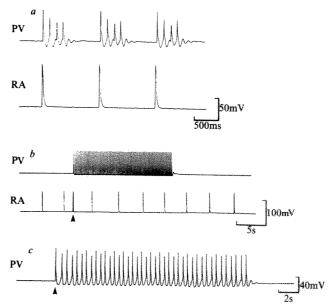

Fig. 4 Conduction block between PV and RA in the presence of ouabain (2.5  $\mu$ M). a, In this preparation, repetitive activity at the PV was coupled to the sinus beats. b, The PV was not coupled to the RA and was electrically quiescent. A single electrical stimulus applied at the PV close to the heart elicited repetitive activity at the PV and an action potential at the RA. In both cases, repetitive activity at the PV did not propagate into the RA. c, After being severed from the heart, repetitive activity could still be generated at the PV with electrical stimulation.

equilibrium potential, leading to a reduction in the amplitude of action potentials. The amplitude of OAPs might also be reduced if the transient inward current responsible for OAPs was also sodium dependent9. The antagonistic effect of high intracellular sodium on OAP may in fact provide a mechanism for spontaneous termination of repetitive activity. With high frequency firing during repetitive activity, the amplitude of OAPs would eventually decrease to below threshold because of the additional influx of sodium with the action potentials. In the brief interval between trains of repetitive activity, the concentration of intracellular sodium may decrease, depending on the degree of poisoning of the pump, and OAPs may again reach threshold for repetitive activity.

#### Autoradiographic localization of GABA<sub>R</sub> receptors in rat cerebellum

#### G. P. Wilkin

Department of Biochemistry, Imperial College of Science and Technology, London SW7 2BX, UK

#### A. L. Hudson, D. R. Hill & N. G. Bowery\*

Department of Pharmacology, St Thomas's Hospital Medical School, London SE1 7EH, UK

 $\gamma\text{-}Aminobutyric$  acid (GABA) is a major inhibitory neurotransmitter in the mammalian cerebellum  $^{1-4}.$  Evidence for the role of GABA in this brain region stems not only from neuropharmacological studies but also from in vitro and ex vivo ligand binding studies with 3H-GABA or 3H-muscimol5-10. The cerebellar concentration of GABA binding sites is higher than that elsewhere 11,12 even though it contains less endogenous GABA than many other brain regions<sup>13</sup>. Using an autoradiographic technique, Kuhar and co-workers<sup>14</sup> have recently demonstrated that these binding sites in the rat cerebellum (detected in Tris-citrate buffer) are located primarily in the granule cell layer, a finding which supports the observations of Candy and Martin<sup>15</sup> and Olsen and Mikoshiba<sup>8</sup> that <sup>3</sup>H-GABA binding is four to six times greater in homogenates of the granule cell layer than in the molecular layer. The GABA sites detected in these studies were bicuculline sensitive and exhibited a high affinity for muscimol. We would therefore classify them as GABAA sites because our recent observations have indicated the presence of other GABA sites (GABA<sub>B</sub> sites) in the central nervous system which are insensitive to bicuculline  $^{16-18}$ . These sites have a high affinity for  $\beta$ -p-chlorophenyl GABA (baclofen), the GABA analogue which is devoid of activity at GABAA sites. We describe here the autoradiographic localization of these GABA<sub>B</sub> sites within the cerebellum and show that, unlike GABAA sites, they are confined almost exclusively to the molecular laver.

As our previous studies on GABA<sub>B</sub> site binding have been limited to membranes prepared from whole rat brain 18,19 first necessary to examine the regional distribution of these binding sites before studying their cellular location within any

\* To whom correspondence should be addressed.

one region. GABA<sub>B</sub> sites can be readily detected in crude synaptic membrane preparations using either <sup>3</sup>H-GABA (50 Ci mmol<sup>-1</sup>, Amersham) or <sup>3</sup>H-baclofen (8.8 Ci mmol<sup>-1</sup> Ciba-Geigy) as the ligand. It is essential, however, that the divalent cations  $Ca^{2+}$  or  $Mg^{2+}$  (1-5 mM) are present in the incubation medium and that Tris-HCl (50 mM, pH 7.4) is used instead of Tris-citrate buffer. Citrate presumably chelates any available divalent ions to prevent binding. High concentrations of Tris will also reduce GABA<sub>B</sub> site binding. In their autoradiographical studies, Palacios et al.14 used 0.3 M Tris buffer to detect GABA binding sites. At this concentration of Tris we found that whereas the GABAA site binding of <sup>3</sup>H-GABA (30 nM) is unaffected, binding to GABA  $_{\! B}$  sites is 57% lower than in 50 mM Tris. Consequently, the incubation and washing solution used for slices in the present study was 50 mM Tris-HCl buffer containing 190 mM sucrose (2.5 mM CaCl<sub>2</sub> was added to the solution used for GABA<sub>B</sub> site binding but was absent in GABA<sub>A</sub> site experiments). This isotonic solution (270 mosmol l<sup>-1</sup>) did not depress GABA<sub>B</sub> site binding and maintained the morphological integrity of the tissue slices for autoradiography.

For the initial distribution studies, separated brain regions were homogenized in 15 volumes of ice-cold sucrose (0.32 M) and pellets obtained as indicated in Table 1 legend, stored at 20 °C and used for assay within 3 days. The pellets were then thawed, washed four times and incubated with fixed concentrations of <sup>3</sup>H-GABA (10 nM) or <sup>3</sup>H-baclofen (20 nM). These are equivalent concentrations of active ligand, as <sup>3</sup>H-baclofen is a racemate and the (-)-isomer is >100 times more potent than the (+)-isomer as an agonist at GABA<sub>B</sub> sites.

Binding to GABA<sub>B</sub> sites was evident in all the brain regions studied and there was a striking correlation between the

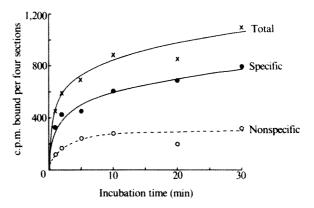

Fig. 1 Time course of <sup>3</sup>H-GABA binding to GABA<sub>B</sub> sites in cerebellar slices. Serial sections of a cerebellum were obtained from a male CSE rat anaesthetized with pentobarbitone before intracardiac perfusion with 0.1% paraformaldehyde in 0.01 M phosphate buffered saline (pH 7.4). The cerebellum was hemisected and immersed in isopentane at -40 °C. Sagittal sections (10 µm) were mounted on glass slides (four per slide) and allowed to dry at ambient temperature for 1 h before storage at -15 °C for at least 16 h. For the binding assay slides were removed from storage for 45 min before immersion in 250 ml Tris-HCl (50 mM, pH 7.4) containing CaCl<sub>2</sub> (2.5 mM) and sucrose (190 mM) for a further 50 min. Each slide was then air dried for 10-15 min after the removal of any excess fluid. Incubation solution (100  $\mu$ l) containing  ${}^3H\text{-}GABA$  (50 nM) and isoguvacine (40  $\mu$ M, to suppress Ca<sup>2+</sup>-independent binding to GABA<sub>A</sub> sites) with (O) or without (×) 100 μM (±)baclofen was applied to each slide and left for 1, 2, 5, 10, 20 or 30 min. The slides were then shaken separately to remove excess incubation solution and rinsed twice very briefly in fresh radioactive-free solution. After drying, the slides were cut and placed in scintillation vials with 0.4 ml distilled water. Scintillation fluid (10 ml Packard ES 299) was added to each vial 30 min later. The c.p.m. values are means of three determinations at each incubation time. Nonspecific values were those obtained in the presence of unlabelled baclofen. The specific values ( ) are the differences between total and nonspecific binding values determined at each incubation time.

The regional distribution of GABA binding sites in rat brain membrane preparations. In each experiment separated brain regions from two rats were homogenized in 15 vol ice-cold sucrose (0.32 M) using a Potter-Elvjehem homogenizer fitted with a Teflon pestle. The homogenates were centrifuged at 1,000g for 10 min and the supernatants recentrifuged at 20,000g for 20 min. The pellets were then resuspended in the original volume of distilled water before centrifuging at 48,000 g for 20 min. The final pellets were frozen at -15 °C for at least 16 h. For the assay each pellet was allowed to thaw at room temperature for 30-40 min before resuspending and washing four times in 6 ml Tris-HCl buffer (pH 7.4, 50 mM) containing CaCl<sub>2</sub> (and isoguracine  $40\,\mu\text{M}$  to suppress binding to GABA<sub>A</sub> sites) for GABA<sub>B</sub> site or Tris-citrate buffer (pH 7.4, 50 mM) for GABA<sub>A</sub> site binding. The final pellet was resuspended in either medium (1-1.5 mg protein per 0.8 ml) solution determined by the method of Lowry et al. 22) for the assay. To each 0.8-ml aliquot 0.1 ml of incubation fluid with or without 1 mM ( $\pm$ ) backofen (GABA<sub>B</sub> site) or 1 mM isoguvacine (GABA<sub>A</sub> sites) was added. A further 0.1 ml containing <sup>3</sup>H-backofen or <sup>3</sup>H-GABA was added to provide final concentrations of 20 nM or 10 nM, respectively. Each mixture was incubated for 10 min at 20 °C and then centrifuged at 7,000g for 10 min. The supernatant was aspirated off and the pellet blotted dry before the addition of 100 µl Soluene and subsequent scintillation fluid. The data are from six separate experiments in each of which binding to GABAA and GABAB sites was determined simultaneously. Values are mean ± s.e.

amounts of <sup>3</sup>H-GABA and <sup>3</sup>H-baclofen specifically bound in each region. The concentration of GABA<sub>A</sub> sites was clearly much greater than that of GABA<sub>B</sub> sites in all regions, with an overall ratio of GABA<sub>A</sub>: GABA<sub>B</sub> sites of 3 or 4:1. The most important finding was the high concentration of GABA<sub>B</sub> sites in the cerebellum, which prompted us to examine the binding in this brain region more closely using an autoradiographic technique.

Brains from rats anaesthetized with pentobarbitone sodium (60 mg per kg intraperitoneally) were fixed by intracardiac perfusion with 0.1% paraformaldehyde in phosphate-buffered saline (0.01 M pH 7.4, 10 min perfusion with 200 ml). In some experiments higher fixative concentrations were used to see whether this affected the subsequent binding. At concentrations below 0.5% paraformaldehyde saturable binding was readily detected and apparently independent of the fixative concentration whereas above this concentration (up to 4%) it was markedly reduced and extremely variable. Sagittal slices (10 µm thick) of cerebellum were obtained by cryostat sectioning and four slices placed on single glass slides. The slices were allowed to dry at ambient temperature for 1 h before freezing at -20 °C. The tissue was stored in this manner for up to 1 week without any noticeable impairment in its ability to bind <sup>3</sup>H-GABA to either GABA<sub>A</sub> or GABA<sub>B</sub> sites.

3H-GABA (50 Ci mmol<sup>-1</sup>) rather than 3H-baclofen was used

<sup>3</sup>H-GABA (50 Ci mmol<sup>-1</sup>) rather than <sup>3</sup>H-baclofen was used for the experiments because it has a higher specific activity than <sup>3</sup>H-baclofen and no inactive enantiomer. Qualitatively similar results were obtained with <sup>3</sup>H-baclofen binding to GABA<sub>B</sub> sites but, as expected, the background radioactivity was higher and the total radioabelling lower than with <sup>3</sup>H-GABA.

For the binding experiments the slices were allowed to thaw and dry for 45 min and then washed for 50 min by immersion in incubation solution (250 ml per 30 slides). After drying, 0.1 ml incubation solution containing 40 nM <sup>3</sup>H-GABA with or

without unlabelled displacing agents was applied to each slide. This was subsequently removed by shaking and two brief rinses in large volumes of the appropriate Tris-sucrose solution. The slices were then either placed in a vial for scintillation spectrometry or kept for autoradiography (see Fig. 3 legend).

Figure 1 shows the time course of  ${}^{3}\text{H-GABA}$  binding to GABA<sub>B</sub> sites in these conditions. The sections were incubated with  ${}^{3}\text{H-GABA}$  in the presence of 40  $\mu$ M isoguvacine (to prevent GABA<sub>A</sub> site binding) with or without unlabelled ( $\pm$ )baclofen (100  $\mu$ M). The total amount of  ${}^{3}\text{H-GABA}$  bound increased with time for at least 20 min, whereas in the presence of unlabelled baclofen the amount bound (nonspecific binding) was constant after 5 min. The specific portion of binding (total minus nonspecific) remained constant after 20 min incubation and >85% of this had occurred by 15 min. All subsequent studies were performed using incubations of 15 min, by which time the specific portion comprised 75.4±2.3% (mean±s.e.m., n=9; triplicate determinations) of total binding. In the same conditions  ${}^{3}\text{H-GABA}$  binding to GABA<sub>A</sub> sites formed 90.1±1.6% (n=4 in triplicate) of the total binding.

Scatchard analysis of specific  $^3$ H-GABA binding to GABA<sub>B</sub> sites in cerebellar slices indicated the presence of a single saturable binding component  $K_d = 159$  nM,  $B_{\rm max} = 83.6$  fmol per 4 slices (Hill coefficient = 0.97). The apparent affinity of this component was therefore slightly lower in slices than previously observed in homogenates ( $K_d = 77$  nM), perhaps reflecting the presence of endogenous inhibitors in the intact slices which may be removed in the homogenate preparations.

<sup>3</sup>H-GABA which was specifically bound to GABA<sub>B</sub> sites in slices could be displaced by analogues shown previously to be

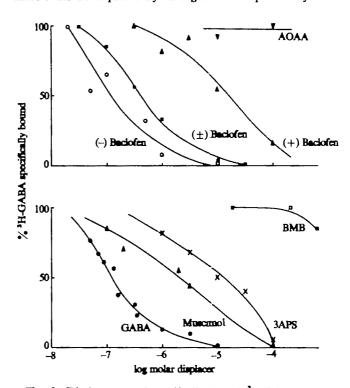

Fig. 2 Displacement of specifically bound <sup>3</sup>H-GABA from GABA<sub>B</sub> sites in rat cerebellar slices by unlabelled GABA-related substances. Cerebellar slices were obtained and treated in the same manner as described in Fig. 1 legend except that all slices were incubated for 15 min and various concentrations of different unlabelled analogues were added to the incubation solution. Total specific binding in any experiment was that portion of <sup>3</sup>H-GABA displaced by 100 μM (±)baclofen. The displacement produced by each concentration of analogue is expressed as a percentage of that occurring with (±)baclofen (100 μM). The data have been separated for clarity. Each value is the mean of three determinations (four slices per determination). Standard errors were <5%, ○, (-)Baclofen; Ⅲ, (±)baclofen; ▲, (+)baclofen; ▼, aminooxyacetic acid; ⊕, GABA; △, muscimol; ×, 3-aminopropanesulphonic acid; □, bicuculline methobromide.

active at GABA<sub>B</sub> sites in homogenates as well as whole tissue assays. Slices were incubated simultaneously with  $^3$ H-GABA and various concentrations of unlabelled displacer (as well as 40  $\mu$ M isoguvacine) and the combined data from these experiments are shown in Fig. 2. GABA and (–)baclofen were equipotent in displacing  $^3$ H-GABA, with IC<sub>50</sub> values of 120 nM. The IC<sub>50</sub> values for the other analogues were 400 nM ( $\pm$ )baclofen, 2  $\mu$ M for muscimol, 12.6  $\mu$ M for 3-aminopropanesulphonic acid and 15.8  $\mu$ M for (+)baclofen, an order of potency which accords with the analogue specificity observed previously in homogenates  $^{16}$ . As expected, bicuculline metho-

bromide  $(100 \, \mu M)$  and the GABA transaminase inhibitor aminoxyacetic acid (AOAA) were inactive. In the latter case, as both GABA and AOAA would be expected to bind to the active site of the enzyme, the absence of effect of AOAA suggests that the transaminase enzyme is unlikely to be the binding site in slices.

Inhibitors of GABA transport—cis-3-aminocyclohexane carboxylic acid (ACHC), nipecotic acid and 2,4 diaminobutyric acid (DABA)—produced no displacement at  $10~\mu M$  and less than 20% displacement at  $100~\mu M$ ; the IC<sub>50</sub> values were all  $\gg 1~mM$ . It is therefore unlikely that the binding site is a trans-

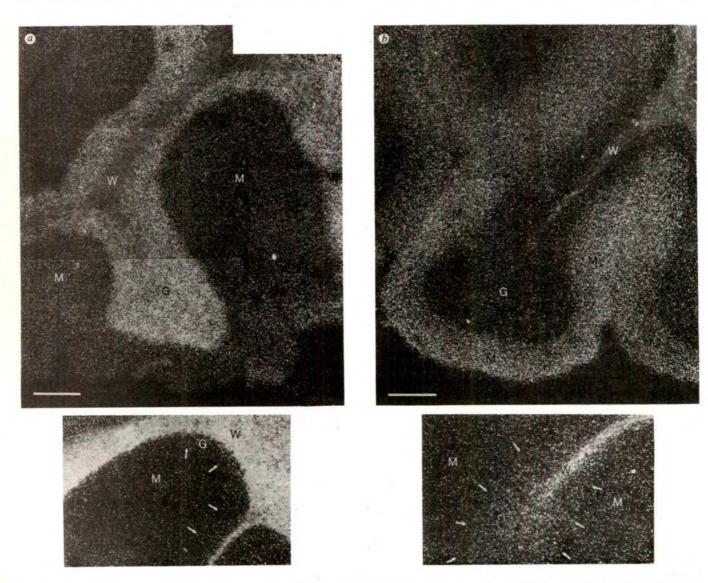

Fig. 3 Light microscopic darkfield autoradiograms of <sup>3</sup>H-GABA binding to GABA<sub>A</sub> sites (a) and GABA<sub>B</sub> sites (b) in rat cerebellum. Cerebellar cryostat sections were obtained as described in Fig. 1 legend. After thawing and drying for 45 min the sections were immersed in Tris-HCl solution containing sucrose (190 mM) with (GABA<sub>B</sub> sites) or without (GABA<sub>A</sub> sites) CaCl<sub>2</sub> (2.5 mM) for 50 min. For GABA<sub>A</sub> site binding, 100 µl of incubation fluid containing 3H-GABA (50 nM) with (nonspecific binding) or without (specific binding) unlabelled isoguvacine (100 µM) was applied for 15 min. This was removed by shaking and two brief rinses in large volumes of incubation medium. For GABAB site binding the same procedure was followed except that the incubation medium contained CaCl2 (2.5 mM) and isoguvacine (40 µM) to suppress binding to GABA<sub>A</sub> sites. Nonspecific binding was determined by the addition of  $(\pm)$ baclofen  $(100 \,\mu\text{M})$ . After drying, the slides were prepared for autoradiography following the procedure of Young and Kuhar<sup>23</sup>. Coverslips that had been dipped in Ilford K5 emulsion (emulsion : water 1:1.5) were attached to the slides with Loctite glue and batches of six slides were held together with bulldog clips and exposed for up to 12 days at +4°C in a sealed box containing silica gel. Slides were developed at 16°C in Kodak 19b developer (3.5 min) and fixed in 25% sodium thiosulphate solution. Following several washes in glass distilled water the slides were dried overnight and the coverslips were then permanently fixed in position with DPX mounting medium. Sections were viewed under dark field optics with a Leitz Ortholux II microscope and photographs taken with Ilford FP4 film. GABAA sites (a): The greatest concentration of silver grains can be seen over the granule cell layer (G) and a lesser concentration over the molecular layer (M). Very few grains are present over the white matter tract (W). The smaller photograph below shows nonspecific binding. The boundary between the molecular and granule cell layers is indicated by the arrows. GABA<sub>B</sub> sites (b): In contrast to a, the greatest accumulation of silver grains is over the molecular layer (M) with a lesser amount over the granule cell layer (G) and white matter (W). In the section below, displaying nonspecific binding, the boundary of the molecular and granule cell layer is again delineated by arrows. The white matter tracts in such sections show varying degrees of light scattering; here it is greater in the blank (lower picture) than in the experimental section. Such light scattering, however, does not hinder the counting of silver grains. Scale bar, 300 µm.

Table 2 Autoradiographic grain densities over cerebellar layers following 3H-GABA binding to GABA, GABA, and both sites together in 10-µm cryostat sections

	GABA <sub>B</sub> sites			GABA <sub>A</sub> sites		GABA <sub>B</sub> and GABA <sub>A</sub> sites  Total -			
Layer	Total	Nonspecific	Total – nonspecific	Total	Nonspecific	Total nonspecific	Total	Nonspecific	nonspecific
White matter Granule cell layer Molecular layer	1.21±0.16 1.64±0.17 3.82±0.17	$1.08 \pm 0.07$ $1.12 \pm 0.08$ $1.09 \pm 0.05$	0.13 0.52 2.73	$1.44\pm0.12$ $9.88\pm0.62$ $3.85\pm0.18$	$0.87 \pm 0.08$ $0.94 \pm 0.08$ $1.10 \pm 0.19$	0.57 8.94 2.75	1.24±0.36 10.47±0.83 6.38±1.06	$0.76\pm0.06$ $0.85\pm0.05$ $0.95\pm0.05$	0.48 9.62 5.43

Densities were quantified after 1 week's exposure using an eyepiece graticule. In each case the mean ±s.e.m. was obtained after counting four separate areas each of 5,400  $\mu m^2$  on two slides. Values are grains per 100  $\mu m^4$ .

port recognition site for GABA, and this is supported by the Na+ independence of binding in slices.

The close comparison between the pharmacological specificity observed in slices and homogenates indicated that it was appropriate to proceed with autoradiography in the slices. Thus, slides which had been incubated in <sup>3</sup>H-GABA to label GABAA or GABAB sites were dried, coverslips coated with emulsion (Ilford K5) were placed in contact with the sections, and the slides were stored in boxes at +4 °C for 6-12 days before developing. Figure 3 gives results from two slices from the same cerebellum after 12 days' exposure. Figure 3a shows the distribution of silver grains after incubation with <sup>3</sup>H-GABA (50 nM) in the absence of Ca2+ and presence of 100 µM (±)baclofen; the associated background picture was obtained by the further addition of isoguvacine (100 µM). Figure 3b shows the distribution after incubation with <sup>3</sup>H-GABA in the presence of 2.5 mM CaCl<sub>2</sub> and 40 μM isoguvacine; (±)baclofen (100 μM) was further added to obtain the background picture. The distribution of silver grains in the two incubation conditions was markedly different. GABA, site binding (Fig. 3a) occurred primarily in the granule cell layer whereas GABA<sub>B</sub> site binding (Fig. 3b) was confined to the molecular layer. The grain counts for these individual layers are shown in Table 2.

Concomitant experiments using slices from the same animal were subjected to analysis by scintillation spectrometry. The mean radioactivity (c.p.m. values per four slices,  $\pm$ s.e.m., n = 6) for GABA<sub>A</sub> and GABA<sub>B</sub> sites, respectively, were 3,591±269 (background  $393\pm156$ ) and  $962\pm3$  (background  $236\pm66$ ). The specific portions were therefore 3,198 and 726 c.p.m., respectively, which represents a ratio of 4.4:1. When slices were incubated in <sup>3</sup>H-GABA in the presence of Ca<sup>2+</sup> alone to obtain the total GABA, and GABA, site binding, the value was  $4,203 \pm 303$  c.p.m. (background  $236 \pm 34$ ). The specific portion was then 3,967 c.p.m., which was identical with the sum of the

separate data  $(3,198\pm726=3,924 \text{ c.p.m.})$ . The present study has shown that  $Ca^{2+}$ -dependent GABA binding sites (GABA<sub>B</sub> sites) in the rat cerebellum are localized almost entirely within the molecular layer. Whether these sites are functional remains to be seen, although it may be pertinent that whereas the number of presumed GABA nerve terminals is similar in the molecular and granule cell layer, 'classical' GABA, sites are unequally distributed14. The presence of GABA<sub>B</sub> sites may explain this apparent deficit of GABA

receptors in the molecular layer.

We do not know the cell type(s) on which the GABA<sub>B</sub> sites are located. Evidence from release studies has suggested that they are present on presynaptic terminals where they modulate transmitter release 16,20. However, we know of no morphological evidence for axo-axonic synapses on terminal boutons in the molecular layer21. Thus, allowing for the fact that such a population may not have been recognized, other possibilities are that GABA<sub>B</sub> sites are (1) non-innervated (2) present postsynaptically on morphologically 'conventional' axo-dendritic synapses or (3) present on glial cells. This third possibility seems unlikely because there is no autoradiographic evidence of binding over fibrous astrocytes present in white matter, and pellets enriched in synaptic membranes show a high degree of binding. Work is in progress to investigate these possibilities.

#### Neurotensin receptors are located on dopaminecontaining neurones in rat midbrain

#### Jose M. Palacios & Michael J. Kuhar\*

Departments of Neuroscience, Pharmacology and Experimental Therapeutics and Psychiatry and the Behavioral Sciences, The Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, USA

Neurotensin is a putative peptide neurotransmitter in the mammalian brain; neurotensin-containing neurones neurotensin receptors have been identified in the brain both blochemically and histochemically<sup>1-7</sup>. There is strong evidence for an interaction between dopaminergic systems and neurotensin<sup>7-11</sup>. Related to this, light microscopic radiohistochemical studies have shown a dense localization of neurotensia receptors in the substantia nigra zona compacta and the adjacent ventral tegmental area of the rat midhrain. These studies suggest a high concentration of neurotensin receptors on dopaminergic cell bodies. Here we report a large, local depletion of neurotensin receptors in the substantia nigra zona compacta after a local 6-hydroxydopamine injection, indicating that endogenous neurotensin or related drugs could have potent effects on dopaminergic function in the brain.

<sup>\*</sup> To whom correspondence could be sent.

Male, Sprague-Dawley rats (225-275 g) were used in our experiments. 6-Hydroxydopamine (Sigma) was dissolved in saline containing 0.2 mg ml-1 ascorbate to give a final concentration of 2 mg ml-1 and 6 µg of drug were injected over a 5 min period with a Hamilton 5 µl syringe, which was placed stereotaxically over the substantia nigra as previously described12 Three animals were injected with drug and three were injected with saline as controls. Four weeks after injection, the animals were killed and tissues prepared for receptor autoradiography as previously described<sup>7,13,14</sup>. Sections (8 μm) of midbrain were thaw-mounted on to microscope slides and neurotensin receptors labelled by incubating the sections in 4 nM <sup>3</sup>H-neurotensin (64.3 Ci mmol<sup>-1</sup>; New England Corporation) in 0.17 M Tris-HCl buffer pH 7.6 at ice-bath temperatures. The buffer contained 0.05% boiled bovine serum albumin (BSA) and 0.1 ml bacitracin. After incubation, the sections were washed twice for 5 min in the same buffer at 2 °C to reduce nonspecific binding. Blank values were obtained by adding 5 µM neurotensin tmparallel incubations. Extensive biochemical studies have shown that binding of neurotensin to the slide-mounted tissue sections in these conditions is predominantly to the neurotensin receptor<sup>7</sup>. Autoradiographs, produced by the apposition of <sup>3</sup>H-Ultrofilm (LKB) in X-ray film cassettes<sup>14</sup>, were exposed for 30 days at 2 °C. After development, the autoradiographic grain densities were determined quantitatively using a micro-

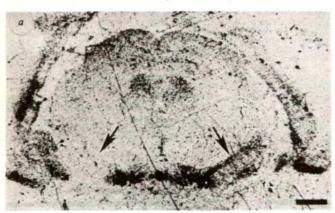

Fig. 1 Autoradiographic localization of neurotensin receptors to dopaminergic neurones in rat substantia nigra zona compacta. Injection of 6-hydroxydopamine results in a loss of neurotensin receptors and dopamine-containing cells in the substantia nigra zona compacta (see text for details). a, Photomicrograph of the autoradiographic image of the rat midbrain on <sup>3</sup>H-Ultrofilm. Note the loss of radioactive ligand binding on the left (at arrow) where the 6-hydroxydopamine was injected, compared with the binding on the right where receptor densities parallel the distribution of dopamine-containing cells. Scale bar, 1 mm. b, c, Higher power photomicrographs of the cresyl violet-stained section used to produce the image in a. The photomicrographs were taken at the arrows in a. Note the loss of cell bodies in the zona compacta in b (corresponding to the injected left side in a) compared with the opposite uninjected side, shown in c. Scale bar, 100 μm.

Cortical nucleus of					
the amygdala	$161.1 \pm 19.0$	$162.3 \pm 28.3$	+1*		

Data are mean ± s.e.m. of at least two tissue sections from each of three different animals. Data were obtained by measuring the optical densities of the autoradiograms as described in the text. By using autoradiographic standards, the optical densities were converted to fmol of ligand bound. Blank values of receptor binding were quite low and have been subtracted. Thus, the data represent specific receptor binding.

\* No significant difference, Student's t-test.

densitometer (Gamma Scientific) with a 100-µm aperture. Autoradiographic standards were included in each experiment so that grain densities could be transformed to fmol of neurotensin bound.

In these rat midbrain sections, the receptor distribution was identical to that previously reported<sup>7</sup>. High densities were found in the substantia nigra as well as in the adjacent ventral tegmental area. Neuronal elements containing immunoreactive neurotensin have been detected in this area<sup>3</sup>. High densities of receptors were also found in the cortical nucleus of the amygdala, rhinal sulcus and in parts of the cerebral cortex. Serial, adjacentsections incubated with excess neurotensin to provide blanks, did not produce any significant elevated grain densities in hese areas.

Injection of 6-hydroxydopamine caused a reproducible and substantial loss of cell bodies in the substantia nigra zona compacta. There was also a striking loss of neurotensin receptors in the substantia nigra that did not extend into the medial ventral tegmental areas (Fig. 1). No loss of receptor occurred in the saline-injected controls (data not shown). Thus, there was receptor loss only in areas showing cell destruction. Biochemical studies indicated a 75–80% reductionin dopamine levels in the ipsilateral striatum confirming a loss of dopamine cells in the injected substantia nigra (data not shown). There was no nonspecific loss of cells at the injection sites as benzodiazepine receptor levels were not decreased substantially in adjacent serial sections (data not shown).

To quantitate the changes in receptor distributions, the autoradiographic grain density was determined by microdensitometry (Table 1). There was a 90% loss of neurotensin receptors on the injected side of the substantia nigra. By contrast, areas unaffected by the lesion, such as the ventil tegmental area, rhinal sulcus and cortical nuclus of the amygdala, did not show any significant change in receptor density.

These results indicate that at least some dopamine-containing neurones in the ventral midbrain of the rat have very high densities of neurotensin receptors. This is corroborated by the recent finding of Andrade and Aghajanian<sup>15</sup> that neurotensin is a highly potent and reliable excitant of dopaminergic neurones in iontophoretic studies. Our results, taken together with those of others<sup>7-11,15</sup>, agree with the general idea of a neurotensin-dopamine interaction in brain, probably at several sites<sup>3,7-11</sup>. Dopaminergic neurones are presumably affected byother peptides including enkephalins<sup>16</sup>, cholecystokinin<sup>17</sup> and substance P<sup>18</sup>. Thus, the development of peptide agonists and antagonists may be useful in the treatment of syndromes involving dopaminergic neurones.

We thank Ms Darlene Weimer for clerical assistance, Mrs Naomi Taylor, Ms Anne Foard and Mrs Theresa Kopajtic for technical assistance and Dr Joseph Coyle and Mr Robert Zaczek for the measurement of the striatal dopamine levels. This work

was supported by USPHS grants MH25951 and MH00053 (M.J.K.) and TW02583 (J.M.P.).

#### Isolation and biogenesis of a new peptide from pancreatic islets

#### Thue W. Schwartz\* & Howard S. Tager

Department of Biochemistry, University of Chicago, Chicago, Illinois 60637, USA

Pancreatic polypeptide (PP) was discovered as a major peptide contaminant of insulin preparations<sup>1,2</sup>. The peptide is stored in a distinct endocrine cell type<sup>3</sup> that is the predominating islet cell in the duodenal part of the pancreas<sup>4</sup> and it is released in response to physiological events, including food intake<sup>5</sup> and decrease in blood glucose<sup>6,7</sup>. Furthermore, infusions of PP mimicking physiological fluctuations in plasma concentrations of the peptide affect gastrointestinal functions, by inhibiting exocrine pancreatic secretion<sup>8-10</sup> and relaxing the gallbladder<sup>10,11</sup>. and relaxing the gallbladder1 Although the PP cell is more sensitive to small reductions in blood glucose than is the glucagon cell<sup>6</sup>, many studies have failed to demonstrate any metabolic effect of PP<sup>12,13</sup>. It is recognized that the biogenesis of secretory peptides by conversion of larger precursors results in multiple peptide fragments of which more than one might be bioactive 14-16. Recently we identified a precursor of PP with a molecular weight (M,) of 8,000-10,000 and showed, by pulse-chase experiments and peptide mapping, that this biosynthetically labelled precursor was converted into a low molecular weight peptide in addition to PP17. We report here the isolation and primary structure of this icosapeptide and show how it arises through an intermediate form by post-translational modification of the COOH-terminal part of the PP precursor. This second product of pro-pancreatic polypeptide conversion might fulfill the physiological potential of the major endocrine cell type of the duodenal pancreas.

To obtain amounts of the co-synthesized pro-PP-related product sufficient for structural, immunological, and biological studies, we used the biosynthetically labelled peptide as a probe. Duodenal lobes of canine pancreas which are especially rich in PP<sup>18</sup> were extracted in acid ethanol and gel-filtered. As shown in Fig. 1a, a peak of absorbance (280 nm) eluted at the position of the biosynthetically labelled fragment of the PP precursor (fractions 125-135). This peak was not obvious when extracts were prepared from the splenic part of the pancreas, which is deficient in PP (data not shown). Only one major peptide eluting with the labelled fragment of the PP precursor was detected by polyacrylamide gel electrophoresis (Fig. 1a inset). (The proinsulin connecting peptide (C-peptide) which elutes in a similar position neither absorbs at 280 nm nor is it fixed and stained in the polyacrylamide gel system used.) The peptide was further

purified by DEAE-anion-exchange chromatography (Fig. 1b) and by paper electrophoresis using polyacrylamide gel electrophoresis as a monitoring system. The amino acid composition of the purified peptide, determined after acid hydrolysis using an amino acid analyser (Dionex) is as follows: Asp, 2.08; Ser, 0.86; Glu, 2.02; Pro, 1.81; Gly, 2.01; Ala, 2.91; Met, 0.68; Ile, 0.95; Leu, 1.05; His, 1.04; Arg, 3.02. The peptide had an absorbance at 280 nm compatible with the presence of one tryptophan residue, giving a total composition of 20 amino acids. Aspartic acid was determined as the NH2-terminal residue by identification of the corresponding dansyl derivative on polyamide sheets (A 1700; Schleicher & Schuell) after treatment with dansyl chloride. The primary structure of the icosapeptide was determined by manual Edman degradation and by degradation with carboxypeptidase Y; the sequence and details of the methods used are given in Fig. 2 legend.

Both chemical and immunological experiments were performed to determine the structural relationship between the isolated icosapeptide and the biosynthetically labelled material

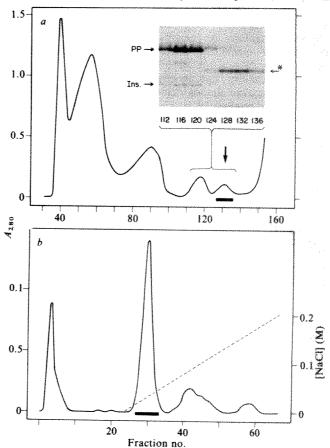

Fig. 1 Purification of the new peptide arising from pro-PP conversion. Duodenal lobes of pancreas (~20 g each) were excised from anaesthetized mongrel dogs and immediately homogenized in ice-cold acidified ethanol (0.1 M HCl in 68% ethanol, final concentrations). The homogenate was incubated overnight at 4 °C and centrifuged (40,000g, 25 min). The supernatant was neutralized and the peptides partially purified by ether precipitation<sup>27</sup>. a, Gel filtration profile of proteins extracted from four pancreases on a 2.5×175 cm Bio-Gel P-30 column eluted with 3 M acetic acid. The vertical arrow corresponds to the elution position of the biosynthetically labelled fragment of the PP precursor (peptide III) obtained as described in Fig. 3 legend. The inset shows Amido black-stained peptides after polyacrylamide slab gel electrophoresis (10% acrylamide, pH 8.7; ref. 28) of aliquots from selected fractions of the area shown. The positions of PP and insulin (Ins) standards in the gels are indicated. The asterisk indicates the position of the peptide which was followed throughout the purification. The solid bar shows the fractions which were pooled and evaporated for further purification. b, Elution profile of gel-filtered peptides on DEAE-Sephadex. The ion-exchange column  $(1 \times 4 \text{ cm})$  was equilibrated and eluted at  $4^{\circ}$ C with 0.02 M Tris buffer pH 8.4 containing 6.5 M urea and with a NaCl gradient of 0-0.2 M (400 ml total volume). The solid bar indicates the fractions which were pooled and desalted over Bio-Gel P-2 using 3 M acetic acid. The peptide was further purified by paper electrophoresis on Whatman 1 or 3 paper in 30% formic acid and was cluted from the paper with 88% formic acid at 4 °C

identified in PP cells. Endocrine cells were isolated from canine duodenal pancreas as previously described<sup>17</sup> and purified on a Percoll gradient as described in Fig. 3 legend. The cells were incubated with <sup>35</sup>S-methionine or with <sup>35</sup>S-methionine plus <sup>3</sup>H-leucine and the biosynthetically labelled peptides were studied initially by gel filtration. Three major radiolabelled peptides were detected (Fig. 3a). Peptide I is a biosynthetic precursor of PP which is converted during pulse-chase experiments into PP (peptide II) and its co-synthesized product (peptide III)<sup>17</sup>. The elution profile of labelled peptides from these freshly isolated, single cells was similar to that previously obtained from cultured, aggregated cells ('pseudoislets').

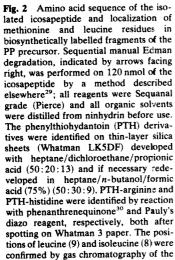

The biosynthetically labelled peptides identified in Fig. 3 were immunoprecipitated with anti-PP antibodies as well as antibodies raised against the icosapeptide (see Fig. 3 legend). The middle profile in Fig. 3a shows that the radiolabelled PP and its radiolabelled precursor are both precipitated by immune complexes prepared with anti-PP antiserum. The lower profile in Fig. 3a demonstrates that the radiolabelled PP precursor and the co-synthesized conversion product, peak III, are both absorbed specifically to immune complexes prepared using antibodies against the newly isolated icosapeptide. Thus, peptide I is specifically immunoprecipitated by antibodies against both PP and the icosapeptide, which shows that the precursor contains immunochemical determinants of both peptides. We have already demonstrated by peptide mapping that tryptic fragments of peptides II and III co-migrate with those of peptide I<sup>17</sup>. These two lines of evidence identify both the structure of the new icosapeptide and that of PP as occurring in the same peptide precursor.

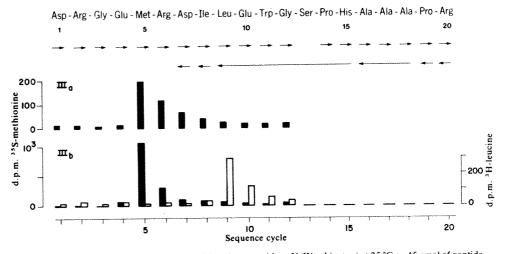

The radiolabelled material in peak III (which was quantitatively immunoprecipitable by antibodies raised against the icosapeptide) separated into two peptides during polyacrylamide gel electrophoresis; one of these co-migrated with the icosapeptide whereas the other migrated more towards the anode at pH 8.7. To study the biosynthetic relationship between these peptides, the radiolabelled peptides obtained from peak III during a pulse-chase experiment were subsequently examined by polyacrylamide gel electrophoresis. As shown in Fig. 3b, upper profile, radioactivity appeared initially in the more anionic peptide, IIIa, during the pulse period. The middle and lower profiles in Fig. 3b demonstrate that during continued incubation in the presence of unlabelled amino acid, the radioactivity in the anionic peptide IIIa first increased (in

agreement with the processing of the precursor during the first 75 min of the pulse period<sup>17</sup>) and eventually decreased, while the radioactivity in the icosapeptide, peptide IIIb, increased. This shift in proportion of radioactivity between the two peptides, both of which are immunoprecipitable by antibodies against the icosapeptide, is consistent with the more anionic peptide being an intermediate in the biogenesis of the icosapeptide, the final product.

To determine the structural relationship between the two peptides eluting in peak III, they were purified by gel filtration and polyacrylamide gel electrophoresis and subjected to sequential Edman degradation. As shown in Fig. 2, <sup>35</sup>S-methionine was identified at position 5 in both peptides; in addition, <sup>3</sup>H-leucine was identified at position 9 in the peptide which co-migrated with the icosapeptide. (Only peptide IIIb originated from a double label experiment.) The positions of these labelled amino acid residues align with the methionine and leucine residues in the NH<sub>2</sub>-terminal sequence of the isolated icosapeptide. The identical position of the methionine residue in the NH<sub>2</sub>-terminal sequence of the two radiolabelled peptides indicates that they differ at their COOH-terminus and that the intermediate form bears a short COOH-terminal extension to the icosapeptide sequence.

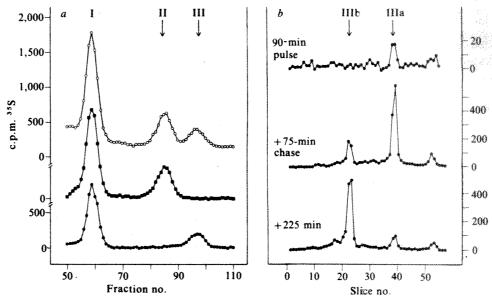

As the pancreatic polypeptide sequence has been localized at the NH<sub>2</sub>-terminus of peptide I<sup>17</sup>, the results shown in Figs 2 and 3 indicate that the icosapeptide originates from the COOHterminal part of the common precursor, from which the icosapeptide sequence is excised as an intermediate form (see Fig. 4); subsequent proteolytic events then refine the COOH-terminal region of the intermediate and result in the mature icosapeptide. The fact that the COOH-terminal residue of the icosapeptide is arginine suggests that an enzyme with a trypsin-like specificity is involved in cleavage of the intermediate form. Converting enzymes for peptide precursors usually require a dibasic amino acid sequence and often remove completely the converting-site residues. However, COOH-terminal arginyl residues are found in epidermal growth factor 19 and nerve growth factor 20, both of which result from precursor cleavage by arginyl peptidases<sup>21,22</sup> In addition, the first two residues (Asp-Arg) are identical to the NH2-terminal residues of angiotensin, which form the site for the specific conversion of angiotensins to des-Asp<sup>1</sup>-angiotensin, angiotensin III<sup>23</sup>. The icosapeptide derived from the processing of the PP precursor may be susceptible to a similar proteolytic modification.

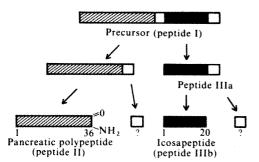

corresponding PTH derivatives. The COOH-terminal sequence was studied by degradation with carboxypeptidase-Y (Worthington) at 25 °C on 45 nmol of peptide with a molar enzyme/peptide ratio of 1:100 in 0.1 M N-ethylmorpholine brought to pH 7.0 with acetic acid. Norleucine (25 nmol) was added for standardization and aliquots removed after the following intervals: 0, 0.5, 1, 3, 5, 10 and 60 min, and 20 h. Free amino acid content was determined using an amino acid analyser. The arrows facing left indicate the amino acid residues which were placed in sequence from the time course of appearance during digestion with carboxypeptidase-Y; long arrows indicate that several amino acids were released too closely to be placed in sequence. No amino acyl phenylthiohydantoin derivative was identified after the arrows indicate that several amino acids were release of serine during carboxypeptidase digestion, as shown, is consistent with a serine at position 13. The 13th cycle of Edman degradation. However, the release of <sup>35</sup>S-methionine (closed columns) and <sup>3</sup>H-leucine (open columns) during manual Edman degradation histograms in the lower part of the figure illustrate the release of <sup>35</sup>S-methionine (closed columns) and <sup>3</sup>H-leucine (open columns) during manual Edman degradation of the biosynthetically labelled PP precursor fragments (peptides IIIa and IIIb) obtained as described in Fig. 3 legend. These peptides were purified by polyacrylamide gel electrophoresis (15% acrylamide) at pH 8.7 (ref. 28) and by elution from the gel slices into 88% formic acid; the peptides were desalted over Bio-Gel P-2 using 3 M acetic acid. The icosapeptide (50 nmol) was used as carrier during both the purification and sequence analysis.

Fig. 3 Biosynthesis of PP and the icosapeptide in isolated endocrine pancreatic cells. Single cells were prepared from duodenal, canine pancreas by trypsin digestion in Ca<sup>2+</sup>-free medium as previously described<sup>17</sup>. The endocrine cells were purified on a Percoll gradient and cells floating to the interface between layers having densities of 1.047 and 1.060 were used. The cells were incubated at 37°C in Eagle's basal medium (with Hanks' salts) lacking methionine, but containing 0.2 mCi <sup>35</sup>S-methionine</sup> containing 0.2 mCi <sup>35</sup>S-methionine (890 Ci nmol<sup>-1</sup>; Amersham). After 4 h, the cells were centrifuged and washed twice before extraction in 1 ml of 3 M acetic acid. The extract was then applied to a 1.5 × 90 cm Bio-Gel P-30 column and the column eluted with 3 M acetic acid 10 mg l<sup>-1</sup> bovine albumin (BSA). a, Elution profiles of peptides appearing in the 12,000–1,000  $M_r$  region. Aliquots from the column fractions were either counted directly or precipitated with preformed

immune complexes prepared against PP or against the isolated icosapeptide as described previously<sup>17</sup>. (Anti-bovine PP antiserum (146-7) was given by Dr R. E. Chance, Lilly Research Laboratories, Indianapolis). Antibodies against the icosapeptide (isolated as indicated in Fig. 1) were raised in a rabbit (3202-2) injected subcutaneously with the peptide coupled through its  $\alpha$ -amino group by difluorodinitrobenzene<sup>31</sup> to BSA. Total radioactivity ( $\bigcirc$ ), radioactivity specifically immunoprecipitated with PP-antibody complexes ( $\blacksquare$ ) and radioactivity specifically immunoprecipitated with icosapeptide-antibody complexes ( $\blacksquare$ ) are shown. Specific immunoprecipitated radioactivity is defined as the difference in radioactivity precipitated in the absence and presence of excess immunocompetitor (bovine PP<sub>1-36</sub> and highly purified icosapeptide, respectively). The void volume of the column corresponds to fraction 31 and PP has an elution position corresponding to peak II. b, Polyacrylamide gel electrophoresis profiles of labelled peptides obtained from peak III during a pulse-chase experiment. Endocrine cells were incubated with 3S-methionine for 90 min (pulse period, top panel) followed by incubation with excess unlabelled methionine for 75 min (middle panel) or 225 min (bottom panel). The radiolabelled peptides were extracted and purified by gel filtration as described for a and peptides eluting in peak III were pooled and subjected to polyacrylamide gel electrophoresis in 8 cm-long gels containing 15% acrylamide. The gels were sectioned into 1.5 mm slices and peptides were eluted into 0.5-ml portions of 88% formic acid. The isolated icosapeptide co-migrated with peptide IIIb in this system; the tracking dye bromophenol blue migrated to slice 53.

Although many large precursor molecules have been identified, only a few cases of the biogenesis of more than one stable peptide product from a single precursor have been documented. A classic example is the biosynthesis of insulin and C-peptide from proinsulin and the co-secretion of the two peptide products<sup>14</sup>. However, the C-peptide apparently serves only as a connector of the two chains of the insulin molecule. The secretion of equimolar amounts of glucagon and a fragment of the NH<sub>2</sub>-terminal part of the glucagon precursor has also been described<sup>16</sup>, but very little is known about the structure of this molecule and its possible function. Proopiomelanocortin, a precursor which contains the sequence of several bioactive peptides such as adrenocorticotropic hormone (ACTH), melanocyte stimulating hormone (MSH), and  $\beta$ -endorphin<sup>15,3</sup> is a more complex example. Post-translational modification of proopiomelanocortin seems to differ between cell types and thus regulates the appearance of the different co-secreted peptides. for example, acetylation of  $\alpha$ -NH<sub>2</sub> groups will activate  $\alpha$ -MSH whilst inactivating the endorphins<sup>25</sup>. Here we have reported the structure of the icosapeptide fragment of the PP precursor, which is stored in similar amounts to PP in the duodenal pancreas. Further studies will establish whether the storage and secretion of the icosapeptide or a related form can solve the

Scheme for the organization of pancreatic polypeptide and icosapeptide within the common precursor and for the conversion of the precursor to its final stored products; PP and the icosapeptide are indicated by hatched and solid bars, respectively. The primary structure of PP has previously been localized to the NH<sub>2</sub>-terminus of the precursor by radiosequencing<sup>17</sup>. Roman numerals refer to the peptide designations used in Figs 2, 3

physiological enigma concerning the function of the PPcontaining cells in the pancreas as well as in other tissues, for example the nervous system.2

We thank D. Glock for help in obtaining the pancreatic tissue and P. Keim and R. Heinrikson for performing the amino acid analysis. This study was supported by grants 512-10545 and 512-15837 from the Danish M.R.C. (to T.W.S.) and N.I.H. grants AM 18347 and AM 20595 (to H.S.T.). T.W.S. is a recipient of a postdoctoral fellowship from the University of Aarhus, Denmark, and H.S.T. is the recipient of Research Career Development Award AM 00145.

### Action of glutamate and aspartate analogues on rod horizontal and bipolar cells

#### R. A. Shiells, G. Falk & S. Naghshineh

Department of Biophysics, University College London, Gower Street, London WC1E 6BT, UK

Electrophysiological evidence indicates that transmitter release from retinal rod terminals occurs at a high rate in the dark and is reduced by light<sup>1-6</sup>. The rod transmitter closes ionic channels (mainly sodium channels) in the subsynaptic membrane of a class of bipolar cells (on-centre bipolar cells) which depolarize in response to light<sup>4,7-9</sup>. However, the transmitter opens sodium channels in the subsynaptic membrane of horizontal cells4 We report here that several compounds, chemically related to the amino acids aspartate and glutamate, have similar postsynaptic actions to that of the rod neurotransmitter. Kainic acid<sup>11</sup>, in micromolar concentration, hyperpolarizes rod oncentre bipolar cells, increasing their membrane resistance while depolarizing rod horizontal cells. Experiments with 2-amino-4phosphonobutyric acid (APB), in which a phosphono group is substituted for a carboxyl group of glutamic acid, have further distinguished between different binding sites on the cells which make synaptic contact with rods. APB is an agonist at the on-centre bipolar cells, closing the same ionic channels as the rod neurotransmitter, but is without effect on rod horizontal cells. The evidence presented here suggest that the widely held view that glutamate or aspartate is the rod neurotransmitter needs to be re-examined.

Intracellular recordings were made in on-centre bipolar cells and horizontal cells of the virtually all-rod retina of the dogfish,  $Scyliorhinus\ canicula$ . Sectors of the dark-adapted eyecup were superfused with oxygenated elasmobranch Ringer's solution at pH7.8 and  $\sim 16$  °C. Equilibration time, after switching perfusion fluids, was several minutes, limited by diffusion through the vitreous and retina. Test flashes of blue-green light, 15 ms in duration, were applied periodically. Full-field illumination was used. Methods of intracellular recording, identification of cells, resistance measurements and light calibration have been described previously.

The effect of kainate on horizontal cells and on-centre bipolar cells is illustrated by typical records in Fig. 1a and b. Figure 1a shows a horizontal cell, depolarized by kainate at a concentration of 2  $\mu$ M, the membrane potential increasing to +6 mV in the presence of 20 µM kainate. The upper trace (recorded simultaneously) shows the progressive decrease in the hyperpolarizing response to light of the horizontal cell with increasing concentration of kainate, the response to bright flashes being almost completely abolished by 20 µM kainate. On removal of kainate, the cell hyperpolarized to a final internal potential of -64 mV, close to its initial value in the dark (shown at the beginning of the lower trace); and, as seen in the upper trace, responses to light also recovered. The effects of kainate on horizontal cells are consistent with an action at the same sites as the rod neurotransmitter but do not rule out the possibility that the effect is exerted at a site presynaptic to the horizontal cell or at extrasynaptic sites on the horizontal cell. However, in other experiments synaptic activity was blocked by 2 mM Co<sup>2+</sup>, making the former possibility unlikely. The addition of Co2+ resulted in hyperpolarization of horizontal cells, to an internal potential between -100 and -120 mV, which was the same as the potential to which the cell could normally be driven by bright

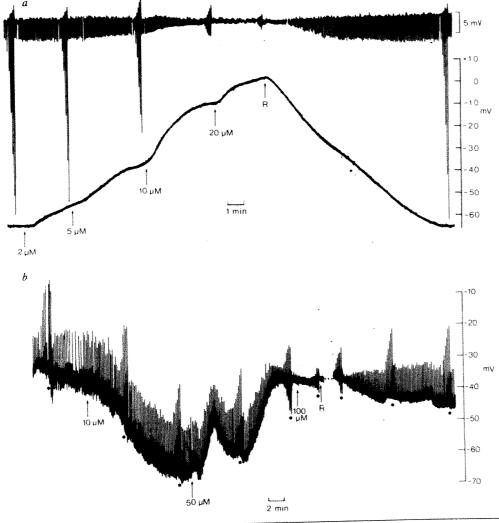

Fig. 1 The action of kainic acid on the membrane potential and response to light of a horizontal (a) and an on-centre bipolar cell (b). In this and succeeding figures, test flashes of constant intensity were applied every 5-10 s; at intervals, the cell's light intensityresponse relation (which appears as a staircase in response) was determined by increasing the light intensity by factors of ~2. a, The upper record shows the response of a rod horizontal cell to flashes, the response being represented as a displacement from the d.c. level in the dark. A sample-and-hold circuit was used to centre the d.c. level about an arbitrary zero before each flash<sup>9</sup>. The lower simultaneous record (at lower gain) shows the d.c. potential of the horizontal cell. Each of the constant test flashes bleached 0.87 rhodopsin molecules per rod (=0.87 Rh\*\*). The brightest flash during each of the intensity-response determinations bleached 67 Rh\*\*. Perfusion with normal Ringer's solution is indicated by R. Normal elasmobranch Ringer's solution contained 280 mM NaCl. 3 mM KCl, 4 mM CaCl<sub>2</sub>, 3 mM NaHCO<sub>3</sub>, 0.5 mM MgCl<sub>2</sub>, 350 mM urea, 10 mM glucose and 5 mM HEPES buffer pH 7.8. b Shows the effect of different concentrations of kainic acid on the membrane potential and response to light flashes of a bipolar cell. Test flashes, each bleaching 0.024 Rh\*\*, were applied throughout the record except when the light intensityresponse relation was determined. Closed circles indicate the brightest flash of the series, bleaching 1.8 Rh\*\* line indicates a break of 15 min in the record.

light, which presumably turns off transmitter release. The addition of  $50-100~\mu M$  kainate resulted in depolarization to an internal potential of about zero, indicating that kainate acts directly on horizontal cells.

In contrast to its action on horizontal cells, low concentrations of kainate (<10 μM) hyperpolarized on-centre bipolar cells. As shown in Fig. 1b, following the addition of 10 µM kainate to normal Ringer's solution, the bipolar cell hyperpolarized by 29 mV to an internal potential of -67 mV. The hyperpolarization was associated with an increase in input resistance from an initial value of  $26 \,\mathrm{M}\Omega$  to  $50 \,\mathrm{M}\Omega$ . After switching to higher concentrations of kainate, from  $50 \mu M$  to  $100 \mu M$ , complex transient effects on on-centre bipolar cells were observed, and responses to light flashes were significantly reduced. It is likely that complex effects on bipolar cells arise from a dual action of kainate, one a direct effect on the bipolar cell, the other arising from depolarization of horizontal cells which interact with bipolar cells. Figure 2 shows evidence that the interaction between horizontal and on-centre bipolar cells involves a synaptic mechanism. When synaptic transmission was blocked by Co<sup>2+</sup>, 100 µM kainate monotonically hyperpolarized the on-centre bipolar cells, driving the membrane potential to values more negative than its normal value in the dark (Fig. 2a). Figure 2b shows the voltage displacements produced by applied current before, during  $\mathrm{Co}^{2+}$  application and during application of Co2+ plus 100 µM kainate. Block of transmitter release by Co<sup>2+</sup> depolarized the bipolar cell by 11 mV to a value of the internal potential which was slightly less than the maximum potential to which it could be driven by bright light. The input resistance decreased to 24 M $\Omega$  from its initial value of 39 M $\Omega$ . During the steady-state hyperpolarization by 100 µM kainate, the input resistance increased to 42 M $\Omega$ . The reversal potential for transmitter action was -15 mV, estimated from the intersection of the linear portion of current-voltage relations in normal Ringer's and during Co2+ block of transmitter release9. These results are consistent with the idea that the rod neurotransmitter closes ionic channels which are relatively selective for Na+. The reversal potential for kainate action, estimated from the intersection of the current-voltage relations during Co<sup>2+</sup> block in the presence or absence of kainate, was estimated to be -13 mV. This result indicates that kainate also closes ionic channels which are relatively selective for Na+. The difference in values of reversal potential are within the error of the method.

The data may also be used to compare the changes in membrane potential with the resistance changes. If the channels closed by kainate and rod neurotransmitter had the same reversal potential, any change in resistance should be proportional to the change in membrane potential, but of opposite sign for a substance which closes channels. This was found to be the case on the assumption that the resistance measurements were not more accurate than  $\pm 5\%$ . It was not possible in these experiments to distinguish whether the effect of kainate was at synaptic or extrasynaptic sites of on-centre bipolar cells. However, extrasynaptic open channels would constitute a shunt on the normal response to light and would reduce synaptic gain on-centre bipolar cells.

The putative transmitters, L-glutamate and L-aspartate, had similar effects on rod horizontal and on-centre bipolar cells to those of kainate, but were at least three orders of magnitude less potent, glutamate being about three times more active than aspartate. The required concentration of glutamate or aspartate was several orders of magnitude greater than expected for a neurotransmitter. As aspartate and glutamate may be transported into the cells and metabolized, the concentration at synaptic sites may be less than in the perfusate. Thus, concentration alone is not sufficient evidence against glutamate or aspartate being the rod neurotransmitter.

To examine further the possibility that glutamate or aspartate could be the rod neurotransmitter, substances which act as antagonists to these putative transmitters elsewhere in the nervous system were tested. One of these was APB, which binds

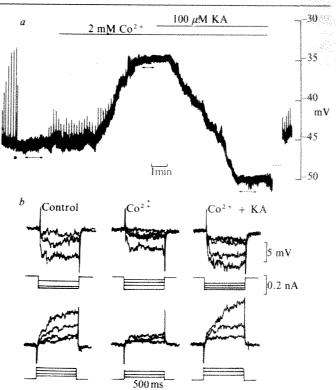

Fig. 2 Effect of kainic acid on membrane potential and input resistance of an on-centre bipolar cell when synaptic transmission has been blocked by Co<sup>2+</sup>. a, Record of the membrane potential and response to 15-ms flashes given at 10-s intervals. At the beginning of the record, the control response to light flashes, increasing in intensity by factors of  $\sim 2$ , is shown. The brightest bleached 4.4 Rh\*\*. The intervals indicated by arrows show the time when resistance measurements were made. The voltage displacements produced by the current pulses have been removed from the record for clarity. Low-intensity test flashes bleaching 0.053 Rh\*\* were applied throughout the rest of the recording. A 15-min/break in the record following the removal of Co<sup>2+</sup> and kainic acid is shown by a dotted line. b, Voltage displacements produced by hyperpolarizing and depolarizing current pulses of 500 ms duration, applied during the intervals shown in a. A single microelectrode was used for applying current and recording voltage. The voltage drop across the resistance in series with the cell's capacitance was balanced by a bridge circuit. The voltage displacement produced 100 ms after current onset, was used in constructing current-voltage curves. Because the records were noisy, the voltage displacements at 90-110 ms at a given applied current were averaged from six to eight records. The input resistance was estimated from the slope of the current-voltage relation in its linear region (displacements of ±5 mV). Some of the apparent nonlinearity in the records is due to time-dependent changes in the resistance of the electrode during current flow. Cell input resistance in the absence of  $Co^{2+}$  and kainic acid (control) was 39 M $\Omega$ ; with 2 mM  $Co^{2+}$ , 24 M $\Omega$ ; with  $Co^{2+}$ plus 100  $\mu M$  kainic acid, 42  $M\Omega$ .

competitively to glutamate-binding sites 13 and acts as a competitive antagonist to glutamate 13,14 at synapses where there is good evidence that glutamate is the excitatory transmitter 15,16 As shown in Fig. 3a, 50 µM APB reversibly hyperpolarized on-centre bipolar cells and blocked their responses to light, despite the increase in driving force for the light response; however, APB had no significant effect on horizontal cells (Fig. 3b). The experiment, illustrated in Fig. 4, in which synaptic transmission was blocked by  $Co^{2+}$  shows that the hyperpolarization of on-centre bipolar cells by APB results from its direct action on the bipolar cell. The increase in input resistance is evidence that APB acts by closing ionic channels. The reversal potential for transmitter action and APB action, estimated from the current-voltage relations, was the same, -31 mV for the cell illustrated. From these results we conclude that APB acts on the same sites of on-centre bipolar cells as those which are controlled by light. The selectivity of its action is due to different binding sites for the rod neurotransmitter on horizontal and on-centre bipolar cells.

APB is similar in size and charge distribution to glutamic acid and is  $\sim 500$  times more effective than glutamate on on-centre bipolar cells. It is interesting that 2-amino-3-phosphonoproprionic acid, which is shorter in length by one carbon

atom (and is the phosphono-analogue of aspartic acid), is also without effect on horizontal cells and is 50-fold less potent than APB on on-centre bipolar cells. The analogue, 2-amino-5phosphonovaleric acid (APV), in which the chain length is increased by one carbon atom, had no effect on on-centre bipolar cells at a concentration of 0.1 mM (at least 20 times the concentration required for a detectable effect of APB). APV has been reported to be a potent antagonist of the excitatory effect of aspartate and glutamate in the mammalian and frog spinal cord<sup>17</sup>. The chemically related compound, D- $\alpha$ -aminoadipate (DαAA) also acts as an antagonist to the excitatory actions of aspartate, and to some extent glutamate, on neurones of the central nervous system  $^{18-20}$ . We found that 5 mM D $\alpha$ AA had no effect on membrane potential or responses to light of on-centre bipolar cells. The racemic mixture (1 mM DLaAA) was also tested on rod horizontal cells and likewise was without effect. This is in contrast to the reported action of DLa AA on horizontal cells with an exclusive cone input, which provided some evidence for aspartate as a cone neurotransmitter<sup>21</sup>. Interestingly, the cone transmitter opens K+ or Cl- channels of oncentre bipolar cells in the retina of teleost fish whereas the rod transmitter closes Na+ channels of the same bipolar cells8.

In view of the finding that glutamate and aspartate are only effective in considerably higher concentrations than required of APB and kainate, and that none of the antagonists tested here showed effects consistent with their expected actions, we suggest

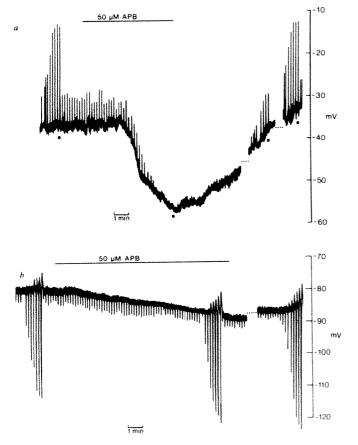

Fig. 3 Selective action of 2-amino 4-phosphonobutyric acid (APB) on on-centre bipolar cells compared with horizontal cells. a, The membrane potential and response to flashes of a bipolar cell. Closed circles indicate when the brightest of the test flashes was used in obtaining the relation between light intensity and response (4.4 Rh\*\* except in the presence of APB when the brightest flash was 8 Rh\*\*). The test flashes used throughout the rest of the record had an intensity of 0.024 Rh\*\*. The first break in the record after washing out APB lasted 3 min, the second 11 min (dotted lines). b, The membrane potential and response to flashes of a horizontal cell. The small hyperpolarization seen after the addition of APB is probably due to a better seal of the electrode in the cell and not due to drug action, as it was not observed in other experiments. The brightest of the flashes in each of the intensity-response series was 136 Rh\*\*. Each of the low-intensity test flashes bleached 0.47 Rh\*\* except after the break in the record lasting 18 min, when the intensity was 0.2 Rh\*\*

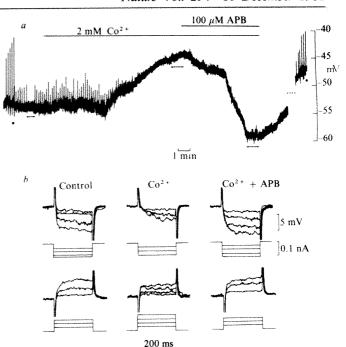

Fig. 4 Effect of APB on membrane potential and input resistance of an on-centre bipolar cell after block of synaptic transmission by Co2+ Membrane potential and response to test flashes. The brightest flash at the beginning and end of the record (shown by closed circles) was of intensity 5.5 Rh\*\* Throughout the rest of the record. except during the intervals 5.5 Rh\*\*. Throughout the rest of the record, except during the intervals shown by arrows, the test flash was of intensity 0.029 Rh\*\*. Resistance measurements were made during the arrowed intervals. The dotted line indicates a break of 12 min. b, Voltage displacements produced by 200-ms hyperpolarizing and depolarizing current pulses. Input resistance estimated in the way described in Fig. 2 legend: control, 42 M $\Omega$ ; with 2 mM Co<sup>2+</sup> 25 M $\Omega$ ; with Co<sup>2+</sup> plus 100  $\mu$ M APB, 54 M $\Omega$ .

that the candidacy of glutamate and aspartate as rod neurotransmitters requires re-examination.

The results raise the possibility that the rod transmitter acts at the same sites of rod horizontal and on-centre bipolar cells as those on which kainate acts. There is evidence that kainate may act at sites which are different from glutamate sites 22-24. That the sites of transmitter binding on rod horizontal cells must be distinct from those of on-centre bipolar cells is shown by the selective action of APB. A similar selective effect of APB on on-centre bipolar cells of the mixed rod-cone retina of the mudpuppy has recently been described<sup>25</sup>.

This work was supported by MRC and SRC grants. R.A.S. was in receipt of an MRC research studentship. Dr T. I. H. Brown participated in early experiments. We thank Drs J. Davies and J. C. Watkins for gifts of compounds.

The Systematics Association Special Volume No 19

# Biosystematics of Social Insects

edited by P.E. Howse and J.-L. Clement

September 1981, xii + 346pp., £28.20 (UK only)/\$68.00, 0.12.357180.4

This volume contains papers by eminent international specialists on social insects submited at a symposium organized by the International Union for the Study of Social Insects in conjuction with the Systematics Association and held in Paris in September 1980. The symposium was devoted to the evaluation of different techniques and the comparison of results. Entomologists, taxonomists and agronomists will all be interested in this important work. In addition, the methodologies and techniques described here will interest all zoologists concerned with the problems of systematics.

# Haemophilus, Pasteurella and Actinobacillus

Proceedings of an International Symposium, August 1980, Cophenhagen, Denmark. edited by M. Kilian, W. Frederiksen and E.L. Biberstein.

October 1981, xiv + 294pp., £14.20 (UK only)/\$29.50, 0.12.406780.8

This book attempts, for the first time, a joint discussion of these three genera of closely related bacteria. It includes reviews of their history, ecology, physiology, and clinical importance in human and veterinary medicine. Results of the application of new methods in taxonomy such as studies of DNA homology, respiratory quinones, enzyme patterns, and electrophoretic analysis of cellular proteins are presented. Collectively, information acquired from these studies allows a more precise definition of the three genera and their species and facilitates the separation of Haemophilus, Pasteurella and Actinobacillus from neighbouring taxa.

# Engineering Calculation Methods for Turbulent Flow

Peter Bradshaw, Tuncer Cebeci and James H. Whitelaw

March 1981, xii + 332pp., £18.60 (UK only)/\$45.00, 0.12.124550.1 Contents: Conservation equations and boundary conditions. Turbulence models based on eddy viscosity hypotheses. Stress equation modelling. Introduction to numerical methods for two-dimensional and steady, three-dimensional flows. Computer program for unsteady two-dimensional boundary layers. Recirculating flows. Viscous inviscid interactions and corner flows. Stability and transition. Wings. Turbomachinery. Combustion.

# Fluorescent Probes

edited by G.S. Beddard and M.A. West

July 1981, x+236pp., £15.20 (UK only)/\$36.50, 0.12.084680.2

The papers collected in this volume were first presented at a meeting, 'Fluorescence Probes in Proteins and Membranes', held at the Royal Institution of Great Britain, in November 1979. Many have been updated by their authors since the meeting. Papers covering the latest time dependent work indicate the value of these measurements for both intrinsic and extrinsic probes. The chemical properties of various site-specific probes are also discussed together with applications to energy transfer and lectin distribution in normal and malignant cells. The book includes a comprehensive bibliography of work in the area between 1970 and 1980.

# **Academic Press**

# The Genetics and Biology of Drosophila

Volume 3a edited by M. Ashburner, H.L. Carson and J.N. Thompson Jr.

November 1981, xvi + 428pp., £40.00 (UK pniy)/\$96.00, 0.12.064945.4

This volume is founded on the remarkable advances made in evolutionary genetics. The first chapter of Volume 3a considers the world fauna. Subsequent chapters explore the geographical distribution, history and special features of the fauna of the Nearctic, Neotropical, Palearctic, Afrotropical, Oriental and Pacific Oceania regions, Australia and New Zealand. There is a chapter on domestic and widespread species and the book closes with a review of bizarre Drosophilidae to round out this broad taxonomic and geographical survey.

# Biology and Control of Take-all

edited by M.J.C. Asher and P.J. Shipton October 1981, xvi+452pp., £41.40 (UK only)/\$99.50, 0.12.065320.6

After a brief historical introduction the taxonomy and biology of the take-all fungus are reviewed comprehensively with reference to the relationship of the pathogen to closely-related species. The ecological, physiological and genetic factors that influence the development of the disease are discussed in some detail and the interaction between the pathogen and the host is examined. In the final section several aspects of take-all disease as it occurs under field conditions are considered.

**GIAM VI** 

# Global Impacts of Applied Microbiology

Sixth International Conference edited by S.O. Emejuaiwe, O. Ogunbi and S.O.

June 1981, viii + 652pp., £20.60 (UK only)/\$49.40, 0.12.238280.3 The Sixth International Conference on Global Impacts of Applied Microbiology (GIAM VI) was held in Lagos between 31st August and 6th September 1980. The proceedings of this conference, published here, not only sets forth the achievements of recent research but demonstrates a dramatic advancement towards the attainment of some of the practical goals of applied microbiology in the modern world: adequate food supply, good health and a clean environment.

Institute of Mathematics and Its Applications Conference Series

# The Mathematical Theory of the Dynamics of Biological Populations II

edited by R.W. Hiorns and D. Cooke

July 1981, xii + 328pp., £14.50 (UK only)/\$35.00, 0.12.348780.3
Based on a conference held in Oxford in July 1980, the book brings together leading mathematicians and biologists to review recent developments in the mathematical study of biological populations. Discussion is centred around two key subjects: the stability and control of populations, and the behaviour and structure of population. Biometrical aspects are also discussed. A worthy addition to the existing volume published in 1973, this work will enhance yet further the interface between mathematics and biology.

#### AIMS AND SCOPE

This journal is an independent international periodical which is published quarterly. It aims to provide a forum for original papers concerned primarily with correlating structure and function in normal and pathological tissues.

Within this context the Journal will be devoted primarily to descriptive and investigative histopathology with respect to improving tissue diagnosis. Good photomicrographs are of particular interest and value to histopathologists and emphasis will be placed on the quality of illustrations published. Original articles dealing with new techniques appropriate to histopathology, cell biology, embryology and teratology in relation to human disease will also be encouraged. Single case reports will not be published unless they are of exceptional interest. Review articles related to current topics of interest together with editorials, a letter column and reviews of recently published books will form regular features of the Journal.

#### EDITORIAL

During the past 4 years the journal "Investigative and Cell Pathology" has attracted and published articles of a high scientific and medical standard which have helped both diagnostic pathologists and those with more scientific interest. Nonetheless, it has become clear that there is a need within the framework of histopathology for a further forum for the presentation of descriptive pathology, especially where functional aspects may be added to provide greater insight into disease processes. It is for this reason that the title of the journal has been changed to "Diagnostic Histopathology". It is hoped, that in doing so, a journal will be provided for histopathologists which they will use while making diagnostic assessments of debatable and

journal will be provided for histopathologists which they will use while making diagnostic assessments of debatable and difficult lesions. The journal will also aim to be one to which histopathologists refer to learn of current improvements in methods of diagnoses or understanding of disease. The high quality of illustrated material established in the journal will continue to be a feature of each publication. It is hoped that the journal will continue to appeal to the scientific as well as the diagnostic pathologist and that it will bridge the gap which is so important to the future improved understanding of disease processes.

# **BOOK REVIEWS**

# **Biochemist extraordinary**

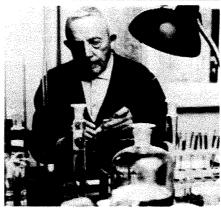

Hans Kornberg

BIOCHEMISTRY has always been, and is likely to remain, an empirical science: a discipline in which knowledge accrues by experiment only. It is therefore not unexpected that major advances in the understanding of biological processes at the molecular level often follow the development of novel experimental techniques. Such developments occur when methods, currently available, are no longer adequate to provide answers to important questions; they usually involve the application to biological problems of technological advances made in other and often unrelated areas of science.

It is rare that one person has the combination of abilities that enables him to distinguish problems that are both important and capable of being resolved successfully, and to initiate and develop the novel means of studying them. It is even rarer to find this combination allied to so ruthless and single-minded a purpose that, for virtually the whole of his adult life, that person subordinates all other activities to the pursuit of his scientific goals. Such a person was Otto Warburg.

As Sir Hans Krebs reminds us in this masterly little book (there are only 81 pages of text, with a further 60 of documentation), Warburg's scientific achievements were immense. In the 1920s he adapted the manometric techniques, developed by Haldane and Barcroft for measurement of the amounts of gases in various body fluids, so that they became the main means not only for analysing a wide range of metabolites but also for measuring the rates at which cellular and sub-cellular events proceed. Warburg's investigation of the structure of the ironcontaining component of the respiratory enzymes, that he had discovered by these techniques, led him to pioneer the use of photoelectric cells and monochromatic light sources to measure its action spectrum. This, in turn, led to the development of the UV spectrophotometer. Together with the Warburg manometer, the widespread use of this instrument permitted the pathways of cellular metabolism to be almost completely elucidated in the 1950s and 1960s. Incidentally, it was Warburg who discovered the identity of most of the coenzymes of respiration, including NAD, NADP, FMN and FAD; who discovered the change in light absorption at 340 nm consequent upon change in the oxidation state of NAD and NADP; and who isolated and purified numerous enzymes of carbohydrate metabolism including some - such as the first enzyme of the pentose

Otto Warburg: Cell Physiologist, Biochemist and Eccentric. By Hans Krebs. Pp.141. ISBN 0-19-858171-8. (Oxford University Press: 1981.) £10, \$24.95.

Otto Warburg at work, July 1966

phosphate pathway — not previously described. It is recorded that Warburg was judged worthy to receive a Nobel Prize on no fewer than three occasions over a period of nearly 20 years, for three separate scientific achievements.

But a price had to be paid for these successes. Throughout his astonishingly long and fruitful career, Warburg deliberately refused to "waste" time in pursuits that would not advance scientific discovery. Thus, apart from his interests in music and a wide knowledge of literature, Warburg shunned ties of family, of friendship or even of scientific fellowship; he did not teach, join committees or tolerate interruptions of his chosen routine. On one occasion, he refused an honorary DSc because he did not wish to devote time to collecting it. One would be tempted to see Warburg as an arrogant, self-righteous and monstrously egocentric despot in his laboratory, were it not for the thoughtful and sympathetic portrait that Sir Hans draws and that colours, with warmth and affection, this otherwise stark picture.

Sir Hans knew Warburg, as his student, colleague and (to some extent) confidant, for half a century. His accounts of the history and significance of Warburg's scientific work, and of the atmosphere in which it was carried out, make fascinating reading for any student of contemporary biology; his assessment of Warburg's

This review was written before the death of Sir Hans Krebs last month. His Reminiscences and Reflections, to be published in January, will be reviewed in Nature at a later date.

personality — his strengths, weaknesses, foibles, warts-and-all — makes equally absorbing reading for any student of human nature. One does not need to be an historian of science to feel a debt of gratitude to Sir Hans Krebs for producing what is as much an eminently readable work of scholarship as it is a labour of love.

Sir Hans Kornberg is Professor of Biochemistry at the University of Cambridge and a holder of the Otto Warburg Medal.

# **Creating confusion**

John D. Barrow

The Creation, By P.W. Atkins. Pp.132. ISBN 0-7167-1350-0. (W.H. Freeman: 1981.) £5.95, \$9.95.

THE memorable Dr Pangloss was introduced to the public by his creator in order to lampoon a traditional but cyclopean perception of the natural world — the prejudice that there exists some benign and covert principle of optimality governing all things. The style of *The Creation* suggests that Pangloss must have had descendants who are not only alive and well but actively popularizing modern science. Ironically, they are no longer theists, but materialists advocating the pursuit of "extreme reductionism and militant rationalism".

The aim of this little book — and it is a good deal smaller than one might think since the text only appears on every other page with footnotes on the alternates - is to convince the lay reader that everything is as it is because it simply could not have been any different. Rather than take the traditional view that some Creator is necessary to explain the existence and arrangement of things, or (the equally traditional view) that he is not, the author argues that by extrapolating contemporary cosmological knowledge we can support a scenario wherein the Deity himself is confronted with what is now an increasingly familiar problem - redundancy. Roughly speaking, it is argued that nature behaves as the ultimate totalitarian state in which everything that is not forbidden is compulsory. By examining the laws and foundation properties of nature (as we now see them), Atkins tries to argue that different universes are not possible and that the traditional craftsman Creator who carefully constructs universes by hand is replaced by the computerized machinery of mathematical necessity.

Suspicions that we might be dealing with a new religion here are confirmed when on p.7 we read that "the only faith we need for the journey is the belief that everything can be understood and ultimately there is nothing to explain". But, I suspect most readers' quarrel with the contents of Atkins's book would not be these aims or declarations of intent but the fact that the case he argues thereafter is also based upon faith or "knowledge" that usually does not vet exist. A Panglossian approach is followed whereby the author creates the type of future knowledge that would support his argument. This argument reminded me of mediaeval "proofs" for the existence of God, and suffers the same weakness that removed their ability to persuade. The disproof of any step in the arguments would not shake their authors' position one inch because the foundation of their belief really rested elsewhere.

That the bulk of the author's argument is speculation is not in itself a bad thing, but if we examine the way in which he handles known facts it ought to give us some guide as to the likelihood that this speculation is reliable. A few results of this rain-check were not too encouraging: he erroneously claims that it is the Lorentz signature of space-time that prevents time-travel; that the rate of biological evolution is exponentially sensitive to the fine structure constant (in fact, doubling the present value of the fine structure constant would, according to modern grand unified gauge theories, cause all protons to decay before stable stars form rather than increase the human evolution time to 1062 years!); and that the temperature of the environment is independent of the fine structure constant (it is actually determined by it).

To my mind, the author does not even get close to showing his case is a scientific possibility since his explanation for the inevitability of the creation of space-time ex nihilo requires an initial state of "almost nothing" — a dust of unstructured points (supplied by a well-known American relativist).

I am afraid that I would not recommend this book to the audience of laymen and students for whom it was created. Scientific popularizers and even scientific evangelists have a responsibility to wait until we know something about the creation of the Universe before telling the public everything about it. If you say, as the author does, that "complete knowledge is just within our grasp", to your professional colleagues it is quite harmless because they will simply laugh at you. To make such a statement in a popular book is totally misleading. This book will be far from enlightening and, I believe, will do little more than create confusion between the known, the unknown and the unknowable in the mind of the inquiring reader.

John Barrow is a Lecturer in Astronomy at the University of Sussex.

# The results of thinking small

Wolfgang K.H. Panofsky

The Nature of Matter. Edited by J.H. Mulvey. Pp.200. ISBN 0-19-8151151-5. (Clarendon/Oxford University Press: 1981.) £8.95, \$15.95.

GOOD popular expositions on particle physics are rare; this is one of them. It is a sequence of separate lectures given by prominent figures in the field at Wolfson College in 1980. In contrast to the common pattern in such series, the lecturers — at least occasionally — cross-refer to one another's talks, and there are other elements of coordination which make the volume rather better than most multiauthor works.

Sir Denys Wilkinson opens the book with an excellent overview, starting with the development of atomistic concepts and ending with the efforts at grand unification of forces and particles. The subsequent discussions of particles and forces are similar to traditional popular presentations of the subject. I found the lecture by Llewellyn-Smith on manifest and hidden symmetries particularly useful, since it gives a comprehensible account of what is more generally called symmetry breaking where the usual layman's exposition leaves the reader in doubt why a broken symmetry is a symmetry at all.

The section by Abdus Salam, on unification of forces, is a straightforward, logical exposition beginning with a historical summary of how the many apparently disjointed forces in nature became understandable in terms of a smaller and smaller set. He then goes into more detail on the history of the unification of the gauge theories of electrodynamics and the weak interaction. His lecture is nicely interwoven with anecdotes; at the same time I fear the reader will gain relatively little understanding of the intellectual content of the theory — this, however, would be a difficult job in any circumstances. The lecture ends with an enumeration of the problems faced in the formulation of a grand unified theory and the alternative approaches to a quantum theory of gravitation.

John Ellis has written a fascinating chapter on the very large and the very small, which is mainly an outline of the extent to which our growing knowledge of the reactions of particle physics limits cosmological models.

I was somewhat less impressed by the experimental sections, in part because they are very brief and overshadowed by the theoretical lectures. The lecture by D.H. Perkins, "Inside the Proton", attempts to give an overview of the quark structure of nucleons and provides the usual quark and lepton tables. The fundamental neutrino scattering experiments which are of particular interest to the lecturer are elaborated, but the balance of the evidence

for hadron structure is covered only briefly. As a result the reader may get a misleading impression that the foundation on which the current theories of hadron structure rest is quite limited, while actually a firm experimental basis exists.

I have a similar reservation about the section on the tools of particle physics. The author, Sir John Adams, concentrates on the history and technical realization of proton circular accelerators. Since he is the creator of the CERN proton synchrotron and super proton synchrotron, this emphasis is fully justified. Yet, on reading this chapter, the layman will underestimate the richness of the arsenal of tools available to the experimentalist, in terms of accelerators, colliders and detectors. In particular - and here my own parochial view is evident - the essential role of electron-positron colliders, which have reaped a substantial fraction of recent discoveries, does not come through. This apart, the lecture includes some illuminating remarks on the social patterns that physicists have established in using the expensive tools of modern particle physics.

As a whole, The Nature of Matter does provide a readable account of various topics in elementary particle physics, ranging over the enormous breadth of dimensions to which modern theory applies. Yet what the layman will miss in the book is the appreciation that understanding of the forces and components of nature depends largely on experiment. The lecturers take little account of the impact of the major experimental discoveries - remember, for instance, the upset when the mu meson turned out not to be the carrier of the strong interaction predicted by Yukawa. Let us recall, too, the many unsuccessful attempts to explain theoretically the experimentally observed tau-theta paradox until Lee and Yang hit upon the right solution; the impact of the cosmic ray discovery of the "hooks and forks" which then became identified with the strange particles, from which then flowed the quark models of Gell-Mann and Zweig; the discovery of the Charmonium peaks which initiated the November Revolution of 1974; and finally the discovery of the third charged lepton which again was not predicted.

Somehow more has to be done in popular accounts of particle physics so that advances in the field are not conveyed as a sequence of events where theorists predict the future, machine builders construct suitable machines, experimenters design instruments and experimental arrangements to test the theory, and then theory is tested. That is not the way it is.

Wolfgang K.H. Panofsky is Director of the Stanford Linear Accelerator Center, California.

# Live issues: the classification of North American mammals

Malcolm C. McKenna

The Mammals of North America, 2nd Edn. By E. Raymond Hall. Two volumes, pp.1,181. ISBN Vol. 1 0-471-05443-7; ISBN Vol. 2 0-471-05444-5. (Wiley: 1981.) \$59.85, £33.25 per volume; two-volume set \$106.40, £59.15.

E. RAYMOND Hall and Keith R. Kelson's compilation of the species-level taxonomy and geographical distribution of living North American mammals, published in 1959, has long been out of print. Now Hall has produced a partly corrected second edition, updated to 1977 and even beyond, but the new version is still marred by many jarring anachronisms.

As before, the work is divided into two volumes. After a brief introduction, the first volume begins with marsupials and then marches through the insectivores, bats, primates, edentates, lagomorphs and the first half of a long section on rodents. The second volume completes the rodents and then moves to the cetaceans, carnivores, sirenians, perissodactyls and artiodactyls. In all of the entries, attention is focused on the traditionally-studied details of coat colour and measurements of the body, limbs, ears and tail - the sort of information one needs when setting out to match a stuffed mouse with specimens in the neatly arranged rows of museum trays. Many illustrations and occasional discussions of skull morphology are also provided, although, for me, details of some dentitions are depicted at too small a scale. There are helpful indexes, a glossary and a long bibliography, and a "how to do it" section deals with collection of specimens, preparation and data preservation.

I believe that the work is still flawed by its typological, philatelic approach - the preoccupation with segregating on the basis of a few selected criteria, mainly Rubicons of size, what might as well be inanimate, history-bereft objects. Although dichotomous keys are employed frequently, these have little phylogenetic rationale and do not deal with morphocline polarities as would be the case if the organisms were treated cladistically. No attempt is made to weed out sharedprimitive characters. Worse, in the keys geographical distributions are all too often used in place of biological characters just as stratigraphical position does not necessarily yield the correct identification

The Biochemistry of the Nucleic Acids, originally written by J.N. Davidson and first published in 1950, has recently appeared in a ninth edition. The new edition has been compiled by R.L.P. Adams together with four other authors at Glasgow University, and is a substantial revision of the last, 1976, edition. The book is published by Chapman & Hall and costs £8.50 in paperback.

of fossils, geographical position does not necessarily give us the correct taxonomic allocation of living organisms. Biological taxa should be recognized by biological criteria alone. Let the stratigraphical and biogeographical chips fall where they may.

According to Hall, about 400 species and subspecies have been added to the living North American mammalian fauna since 1959, bringing the present total up to 3,607. However, although myriads of named (and presumably approved) subspecies are listed and referenced, morphological evidence for their recognition is not presented. Rather, maps depict arbitrary boundaries between localities that produce "marginal specimens" of the putative subspecies. The characterizing features of these - if genuinely biological, and not merely geographically arbitrary or a relic of overly split typological taxonomy — must be sought either in the original literature or elsewhere. Perhaps, in some long-distant future revision, the subject of intraspecific variation can be handled quantitatively. Hall has made a start, but the job is immense.

Finally, Hall's treatment of higher taxonomic categories should be taken with a grain of salt. This is because he deals with members of the living fauna as though they had no history: he does not differentiate between primitive features and phylogenetically significant shared-derived

ones. For example, he seems to be unaware that characters such as an inflected mandibular angle or epipubic bones are not merely metatherian hallmarks but characterize early eutherians as well. Nor does he record that jugal bones reach the glenoid fossa in paenungulates, not just in the Metatheria. Interested readers should also run through the list of mainly primitive features supposedly characterizing Polyprotodontia, Didelphidae or Insectivora (the latter stretched to include the conceptually indigestible macroscelidids). Hall's concept of the "Order Pinnipedia" and his separation of living sloths from megalonychid ground sloths by interlarding the Myrmecophagoidea into their midst will also raise palaeontological and cladistic eyebrows alike.

Hall's work will continue to be useful in spite of its conceptual shortcomings and his apparently stubborn refusal to modify adequately some sections of the first edition which many, even most, mammalogists found objectionable — those dealing with bears, *Dama* and *Lasiurus*, for example.

After all these grumblings, do I recommend the monograph? Yes, of course. After all, what better summary do we have?

Malcolm C. McKenna is in the Department of Vertebrate Paleontology at the American Museum of Natural History, New York.

# An abundance of beetles

M.E.G. Evans

The Biology of the Coleoptera. By R.A. Crowson. Pp.802. ISBN 0-12-196050-1. (Academic: 1981.) £58, \$139.50.

WE LIVE in the age of the obscure beetle. Flowers, fleas, birds and butterflies are all much more obvious organisms, but there are more species in the order Coleoptera than there are in the class Angiospermae, and even, perhaps, than in the whole plant kingdom. Since this enormous species diversity is based upon a common body plan, the variations on this theme should be of great interest to evolutionary biologists as well as specialist entomologists. So where are the hosts of coleopteran biologists?

One reason why biological studies of beetles lag far behind their taxonomy may be a simple failure to appreciate the scope of the subject. What has been lacking until now has been a general biological text which deals with the numerous but scattered studies of beetles. It is just this sort of book which Dr Crowson has written; it is based on well over 1,000 references, including many from non-

English language literature, most of which is recent. However, it is more than a mere compendium of references. In most cases, the information on a topic has been summarized, digested and assimilated into a more general subject area in each of the 20 chapters of text, ranging from morphology and genetics to ecology and evolution. The basic approach is both functional and phylogenetic, although an extended treatment of classification is deliberately omitted. Nevertheless, a family classification is appended, and taxonomic groups in the text are given code numbers which refer to the phylogenetic chart following Chapter 20.

Inevitably, there are some blemishes. Over 300 figures are included, most of which are simple, clear, line drawings, but some have been drastically reduced for printing whilst a few are not reduced enough. Not surprisingly, some topics are discussed in less depth than others, but in most cases these differences in treatment reflect our different levels of comprehension of the subject. Indeed, this has enabled the author to point to obvious gaps

in our knowledge of the Coleoptera over; the whole range of their biology, making one of the most valuable features of the book.

Taken together with its encyclopaedic coverage, these indications of our ignorance will enable *The Biology of the Coleoptera* to provide many potential researchers with a starting point, a basic literature survey and a summary of current knowledge. This is one of the most important books on beetles to be published this century, and it is the first modern text on their biology. I hope it will be bought by many entomologists, evolutionary biologists and science libraries.

M.E.G. Evans is Senior Lecturer in Zoology at the University of Manchester.

# **Puzzles of perception**

Oliver Braddick

Direct Perception. By Claire F. Michaels and Claudia Carello. Pp.200. ISBN 0-13-214791-2. (Prentice-Hall: 1981.) £13.50, \$24.30.

THE perceptual psychologist J.J. Gibson (1904-1979) wrote a series of books which crystallized a theoretical stance he called "ecological optics" and "direct perception". The books were widely read and many details from them became absorbed as standard textbook material, but it seemed for many years that Gibson's basic position was a lonely, almost ignored one, outside the mainstream of thinking on perception. It is still outside the mainstream, but in the years just before and since Gibson's death it has gathered such a vigorous, even strident, group of younger advocates that no one in the field has an excuse for being unaware of it. There has been a particularly zealous Gibsonian cell in and around the University of Connecticut, two of whose members have produced this short, clear, didactic book.

The view against which the authors argue is that the perceiving organism takes in at the sense organs a collection of "raw data" whose relation to objects in the external world is distant and often incomplete, and that the task of perceptual psychology is to discover the computations by which information about the external world is obtained or inferred from these data. The alternative they propose is that perception has to be considered as a function of a system consisting of organism and environment, that the ecologically relevant properties of the environment are present as higher-order invariants in the pattern of energy reaching the senses, and may be detected because the perceptual system "resonates" directly to these higher-order invariants, rather than

computing or inferring anything. Some other advocates of this position have presented it in a manner that appeared to relish shocking, mystifying or finessing more conventional views; here the argument is more orderly and well paced, with its progress charted in summaries of each chapter and at the end of the book. An appendix, "Discussion and Debate", which deals with some queries and criticisms of the argument in question-and-answer form, is very helpful in clarifying just what the authors' position is, although as a debate it is distinctly stage-managed.

It is a valid criticism of much work in sensory and perceptual psychology that it does not give enough thought to what perception is for, or to whether the stimulus variables that are manipulated in perceptual experiments bear any relation to the variables the perceiver needs to use. The opponent that the book sets up is therefore not a straw man, but he lacks flesh in a way that the Gibsonians blithely ignore. The information-processing tradition is centrally interested in problems of mechanism; not only (indeed, not enough) in what job perceptual systems do, but also in how they work. For instance, Michaels and Carello argue that the direct perception approach undercuts the two 'puzzles in binocular vision" which have been "an object of discussion for three millenia" - how can a pair of twodimensional retinal images yield a 3-D percept, and how can it be single? No awareness is indicated that the major binocular puzzle that has interested scientists in the last two decades is not of this kind but is "What kind of mechanism finds pairs of corresponding elements in the two eyes' images?". Now analysis of ecological optics might suggest that this question should be posed in a somewhat different form, but identification of the relevant invariants in the optic array does not abolish the question, how does the system work which "resonates" to them? It is difficult to see how such an answer can be cast except in terms of signals relayed by the sense organs and operations performed upon these signals.

For this reason, scientists working in the information-processing and psychophysical traditions are likely to be impatient with much of Direct Perception. What they would find it hard to deny is that most of the experimental work generated by the direct perception school has been interesting - something they would have to be very partisan to assert of their own tradition. It is perhaps a pity that Michaels and Carello did not make their book 50 pages longer and give us a more detailed awareness of how their approach bears scientific fruit - in the experimental and analytical work of Lee, Shaw and Turvey, among others.

Oliver Braddick is a Lecturer in Experimental. Psychology at the University of Cambridge.

# **Bones** into stones

Mark Newcomer

Life History of a Fossil: An Introduction to Taphonomy and Paleoecology. By Pat Shipman. Pp.222. ISBN 0-674-53085-3. (Harvard University Press: 1981.) \$25, £14.

PALAEONTOLOGISTS are no longer content to classify, weigh, measure and tabulate fossil bones, and are bringing their subject out of the museum through studies of the processes by which the fossil record forms (taphonomy) and through reconstructions of extinct animal communities in their environmental setting (palaeoecology). Recent work in these fields, which to some degree parallels that of archaeologists who attempt to see their sites and artifacts in their geographical context, is the subject of Pat Shipman's lively text.

Much of the book concentrates on the principles, methods of study and results of taphonomic studies of (mainly) African vertebrates, reflecting the author's research interests and competence. She treats her material critically, steering a cautious course through such murky waters as the spiral fracture debates, and stresses the value of suitable quantitative methods for many taphonomic and problems; palaeoecological comments on excavation procedures and "living floors", however, seem a little naive, especially in light of all the recent publications on these matters. (Why does the long reference list contain only Englishlanguage publications? Curious in a book intended as a text.) Without sounding arrogant, I think it is fair to say that standards of excavation have generally been higher in archaeology than in palaeontology, with the fossil hominid hunters perhaps the most culpable, relying on the spectacular nature of their finds to obscure excavation methods which are often mediocre or worse. Similarly, the author could have gone more deeply into the role of hominids in creating both the types and spatial patterns of refuse on sites, given recent experimental work and ethnographic studies by Binford and Yellen, among others.

Intended for "advanced undergraduate courses in anthropology, palaeontology, and evolutionary biology", as well as professionals in these fields, *Life History of a Fossil* will serve as an excellent introduction to taphonomy and palaeoecology. It should also reach a much wider audience with less specialized interests in vertebrate evolution, to whom the lessons to be learned from humble, often broken, bones will come as a pleasant surprise.

Mark Newcomer is a Lecturer in Palaeolithic Archaeology at the Institute of Archaeology, London.

# ANNOUNCEMENTS

#### **Awards**

UC-San Francisco neurologist **Dr Robert** Layzer, has been presented with the 18th annual J. Elliott Royer Award for his contribution to psychiatry and neurology.

The National Association of Science Writers has presented its Science-in-Society Journalism awards for 1981. The winners are: Newspapers — Paul Jacobs, science reporter, the Los Angeles Times, for his series of articles entitled: "Pioneer Genetic Implants". Broadcast News — Ira Flatow, science editor, NPR News, for his two-part broadcast on All Things Considered "Creationism vs. Evolution". Magazines — Janet Raloff, science reporter, Science News, for "Electromagnetic Pulse;" shared with William J. Broad Jr, Science for "Nuclear Pulse."

The Chemical Writers' Awards, sponsored by the Society of Chemical Industry and BASF UK Ltd is this year open to radio and television material as well as the written word. The premier award is the Chemical Writer of the Year, the other classes are: Chemical Reporter of the Year; chemical Application Writer of the Year; and Agrochemical Writer of the year. Material must have been published and circulated or broadcast, in the UK between October 1980 and 31 December 1981. Entries close on 31 January 1982. Entry forms from: Wynn Jones, BASF UK Ltd, PO Box 4, Earl Road, Cheadle Hulme, Cheadle, Cheshire, UK.

Entries are invited for the 1982 Achievement Award presented by the Worshipful Company of Scientific Instrument Makers. The award is intended to bring added prestige to the British scientific instrument industry, to draw attention to new and original products, and to highlight British progress in the field of scientific instruments and electronic technology. Details of suitable achievements should be submitted to the Clerk to the Company, Scientific Instrument Makers Hall, 9 Montague Close, London SE1, UK by the end of April 1982.

The British Vacuum Council seeks to encourage scientists under 27 years of age by inviting entries for its Annual C.R. Burch Prize of £150 for the best submitted paper on vacuum studies, surface science, thin films, or any related topic in which vacuum science or engineering has an important role. Entries by 31 December 1982 to Dr J.S. Collington, Dept of Electrical Engineering, University of Salford, Salford, UK.

## Meetings

21-23 December, Trigger Processes and Cellular Events, London (Miss A. Duffey, Dept of Biochemistry, Royal Free Hospital, School of Medicine, 8 Hunten St, London WC1, UK).

3-8 January, 1982 AAAS National Meeting, Washington DC (A. Herschman, AAAS, 1776 Massachusetts Ave, NW, Washington DC 20036, USA).

5 January, Higher Education: Demand and Access, London (Dr I. Gibbs, The College, Lord Mayor's Walk, York, UK). 5-7 January, Compaction of Particulate Solids, Bradford (Institution of Chemical Engineers, 12 Gayfere St, London SW1, UK).

7 January, Electron Microscopy of Cement and Concrete, London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

11 January, **Dosimetry in Diagnostic Radiology**, London (Dr. D.W. Field, Hospital Physicists' Association, 47 Belgrave Square, London SW1, UK).

12 January, Evolution from Space, London (Omni Magazine, 2 Bramber Rd, London W14, UK).

15 January, Long-range Surveillance of Ocean Surface Wind and Sea State by Ground-based Radar, Edinburgh (Royal Meteorological Society, James Glaisher House, Grenville Place, Bracknell, Berks, UK).

19-21 January, Membrane Recycling, London (Director, The Ciba Foundation, 41 Portland Place, London W1, UK).

20 January, Planetary Meteorology, London (Royal Meteorological Society, James Glaisher House, Bracknell, Berks, IJK)

21 January, Sources of Geological Information for the Caribbean and Latin America, London (Joan Hardy, Library, Chelsea College, Manresa Rd, London SW3, UK).

25 January, Immunochemistry Today, London (School Office, Royal Postgraduate Medical School, Du Cane Rd, London W12, UK).

25-30 January, **Technical Conference on Climate in Africa**, Arusha (World Climate Programme Office, World Meteorological Organization, Geneva, Switzerland).

27 January, Solar Energy for Developing Countries, London (The Administrator, UK-ISES, 19 Albemarle St, London W1, UK).

28 January, The Use of Icebergs, Cardiff (Royal Meteorological Society, James Glaisher House, Grenville Place, Bracknell, Berks, UK).

28-29 January, Maintanance of Deionisation and Reverse Osmosis Plant, High Wycombe (The School of Water Sciences, The Lorch Foundation, Lane End, High Wycombe, Bucks, UK).

\*18-22 January, Electrochemistry, Ventura

\*1-5 February, Chemistry and Biology of Peptides, Ventura

\*1-5 February, Sensory Transduction in Microorganisms, Ventura

\*8-12 February, Cardiovascular Role of Brain Angiotensin and other Peptide Hormones, Ventura

\*8-12 February, **Metal in Biology**, Ventura \*15-19 February, **Alcohol**, Ventura

\*Gordon Research Conferences, Dr A.M. Cruickshank, Pastore Chemical Laboratory, University of Rhode Island, Kinston, Rhode Island 02881, USA.

8-11 February, Protein Structure and Function, Lorne (Dr R.J. Simpson, St Vincent's School of Medical Research, Victoria Parade, Fitzroy, Victoria, Australia).

8-12 February, International Society for Human and Animal Mycology Congress, Palmertston North (The Secretariat, PO Box 63, Palmerston North, New Zealand).
8-12 February, Reticuloendothelial Society Congress, Davos (Prof. E. Sorkin, Schweizerisches Forschuninstitut, Medizinische Abtelling, 7270 Davos-Platz, Switzerland).

15-19 February, Occupational Health and Safety and the Law, Loughborough (The Centre for Extension Studies, Loughborough University of Technology, Loughborough, Leics., UK).

15-22 February, International College of Surgeons Congress, New Dehli (Dr Atm Prakash, C-1/12 Medical Enclave, New Dehli, India).

18 February, Advances in Cardiovascular Imaging, London (British Institute of Radiology, 36 Portland Place, London W1, UK).

19 February, **The Future in Radiology**, London (The Royal Society, 6 Carlton House Terrace, London SW1, UK).

25-26 February, Representing Understanding, London (Dr E.W. Shepherd, Dept of Psychiatry, Guy's Hospital Medical School, London Bridge, London SE1, UK).

26-27 February, **Physiological Society Meeting**, Bristol (Dr D.C. Michel, University Laboratory of Physiology, Parks Rd, Oxford, UK).

26-27 February, **Paediatric Oncology**, London (Royal College of Radiologists, 38 Portland Place, London W1, UK).

28 February — 5 March, Scanning Electron Microscopy in the Biological Sciences, Woods Hole (M.D. Maser, Marine Biological Laboratory, Woods Hole, Massachusetts 02543, USA).

8-10 March, WMO/EPPO Symposium on Meteorology and Plant Protection, Geneva (WMO Secretariat, Research and Applications Programme Dept, Geneva, Switzerland).

QUEEN Elizabeth Hospital — Birmingham Research Technician (Temporary) required in Dept of Medicine for 1 yr only. Research project concerning the isolation and characterization of immune complexes in human glomerulonephritis. Salary £4,220, or on scale £4,958 to £6,993 a for State Registered MLSO's. Applicants with good Hons degree in Biological Sciences, preferably with some grounding in immunology, should submit a full CV to Personnel Officer, Queen Elizabeth Hospital, Edgbaston, Birmingham B15 2TH, from whom further information is available. Closing date: 24th December 1981. (034)A

#### THE MOUNT WILSON AND LAS CAMPANAS OBSERVATORIES of the CARNEGIE INSTITUTION

# OF WASHINGTON Announce the availability of a STAFF MEMBERSHIP

The Observatories seek to make an appointment to their scientific staff in 1982. Staff Members have access to the C1W telescopes on Mount Wilson, on Palomar Mountain, and on Cerro Las Campanas, Chile. A cooperative arrangement between the Carnegie Institution and the California Institute of Technology permits access to the facilities of Caltech's Palomar Observatory.

There is no restriction with regard of field of inquiry, but the person appointed will have at least three years' experience beyond the PhD and will have an established record of achievement in astronomical esearch. Those who might like to be considered for the appointment are nvited to write a letter expressing heir interest to:

Dr. George W. Preston, Director, Mount Wilson and Las Campanas Observatories, 813 Santa Barbara Street, Pasadena, CA 91101-1292, J.S.A.

The letter should be accompanied by a brief curriculum vitae, sibliographic reference to three of he applicant's published scientific apers, and the names and addresses of three scientists familiar with the pplicant's research.

The closing date for the receipt of hese letters will be January 15, 1982.

The Carnegie Institution of Vashington is an Equal Opportunity imployer, M/F/H. (NW141)A

#### UNIVERSITY OF HAMBURG (Germany)

# TECHNICIAN FOR DNA (GENE) SYNTHESIS

Technicians who like to join a research group dealing with DNA synthesis and recombinant DNA research are requested to apply for this position. Experiences in nucleic acid synthesis is of advantage but not necessary. The position is at least for 2 years.

Salary is about DM 25,000 brutto. Applications, together with curriculum vitae, and the names of two referees should be sent to: Prof Dr H Köster, Institut für Organische Chemie and Biochemie, Universität Hamburg, Martin-Luther-King-Platz 6, D-2000 Hamburg 13, Federal Republic of Germany. (W529)A

#### Astronomical Image Processing MOUNT WILSON AND LAS CAMPANAS OBSERVATORIES

# CARNEGIE INSTITUTION OF WASHINGTON

The Observatories are seeking a person with experience in image processing to design, assemble, and upgrade software packages for a VAX 750 computer, located at the Observatories' headquaters in Pasadena, California. The primary responsibility will be de develop useroriented systems for the analysis of digitized photographic plates and two-dimensional data from CCD detectors. Additionally, there may be opportunities for collaborative scientific research with the staff and fellows of the Observatories.

Applicants should have an educational background in either astronomy or computer science, with substantial experience in image processing. The position could be suitable for a scientist seeking postdoctoral experience or for a career data analyst.

Interested persons should send résumés to:

Dr. Alan Dressler, Mount Wilson and Las Campanas Observatories, 813 Santa Barbara Street, Pasadena, CA 91101-1292, U.S.A.

The closing date for the receipt of applications for this position is January 15, 1982.

The Carnegie Institution of Washington is an Equal Opportunity Employer, M/F/H. (NW140)A

# UNIVERSITY OF SOUTHERN CALIFORNIA

DEPARTMENT OF BIOCHEMISTRY AND COMPREHENSIVE CANCER CENTRE

#### ASSISTANT PROFESSOR

Molecular biologist experienced in recombinant DNA techniques and their application to study eukaryotic differentiation. Department of Biochemistry and Comprehensive Cancer Centre, University of Southern California (USC), An Equal Opportunity Employer.

Send CV, bibliography, four references, and a statement of present and future research interests to: Dr Charles Heidelberger, USC Cancer Center, 1721 Griffin Avenue, Los Angeles, CA 90031.

(NW149)A

# UNIVERSITY OF SASKATCHEWAN

DEPARTMENT OF BIOLOGY

Postdoctoral position available to investigate the liposome-mediated transfer of chromosomes into auxotrophic cells of *Datura*.

Candidates should have a strong background in genetics and cell biology and be trained in the use of plant cell culture techniques.

The position is available immediately for a one-year term (renewable for a further two years) at a salary of \$16.380 Can.

Candidates should send curriculum vitae and two letters of recommendation to Dr John King, Department of Biology, University of Saskatchewan, Saskatoon, Sask, Canada S7N OWO. (NW153)A

# nature

has an immediate vacancy in London for an

# ASSISTANT EDITOR

to work primarily on the assessment of physical science manuscripts.

Essential qualifications:

- \* A good science degree
- Some knowledge of the earth sciences
- Some research experience
- A sense of literacy
- \* Wide general interests.

Applications, including a full curriculum vitae, should be plainly marked "Job application" and addressed to the Editor, Nature, Macmillan Journals, 4 Little Essex Street, London WC2R 3LF to arrive before 15 December 1981. Secondment for not less than two years would be appropriate.

(9927)A

# Chief Executive Officer

The Saskatchewan Research Council is seeking a Chief Executive Officer to lead the organization into expanded fields of research in natural resources, energy, industrial engineering and the environment.

The Saskatchewan Research Council, a provincial Crown agency, is one of Canada's major institutions devoted to technological development. Its staff of about 250 undertakes an extensive program of internally initiated research and experimental development, as well as performing contractual and fee-for-service work on behalf of industry and government. Located on the University of Saskatchewan campus in Saskatoon, the Council also has a SLOWPOKE research reactor, new chemical analytical laboratories and pilot plant facilities situated in the adjacent research park.

Saskatchewan is a rapidly-growing and diversifying province. The economy, based on agricultural, mining and energy industries, is forecast to sustain one of the highest rates of growth in Canada during the decade. Saskatoon is a stimulating education, research and business centre noted for its quality of life. Offering a high level of cultural activities, extensive recreational facilities, and affordable homes, the city maintains a friendly community environment.

The Chief Executive Officer will work with leaders in business, government, research and the community at large to foster the role of science and technology in the province. The new Chief Executive Officer will chart the future course for the Saskatchewan Research Council and, with proven skills, will see those concepts and plans implemented. With an established scientific or engineering background, the Chief Executive Officer will be a pragmatic individual committed to Saskatchewan's technological development.

Please reply, in confidence, to the Chairman, Chief Executive Officer Search Committee:

Dr. Douglas Patriquin Executive Council Government of Saskatchewan 3085 Albert Street REGINA, Saskatchewan Canada, S4S 0B1

(NW154)A

# Saskatchewan Research Council

# CSIRO AUSTRALIA

# Research Fellow (Molecular Biology)

\$A19,662 — \$A28,564 pa Molecular & Cellular Biology Unit North Ryde, New South Wales

**CSIRO** has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,500 employees — 2,700 of whom are research and professional scientists — located in divisions and sections throughout Australia.

**General:** The Unit's work includes research programmes on animal cell growth and development, DNA maintenance and modification and gene technology.

**Duties:** To research into DNA repair and mutagenesis and mechanisms of action of bleomycins and phleomycins.

Qualifications: A PhD, or equivalent. Basic training in biochemistry microbiology or microbial genetics.

Tenure: Three years. Superannuation benefits available.

Applications: In writing and stating full personal and professional details, the names of at least two referees and quoting reference No A3314 should reach: The Officer-in-Charge, Molecular & Cellular Biology Unit, CSIRO, PO Box 184, NORTH RYDE, NSW 2113, AUSTRALIA by 8 January 1982. (048)A

## WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales)

SOUTH WALES
RADIOTHERAPY AND

ONCOLOGY SERVICE Velindre Hospital, Whitchurch, Cardiff CF4 7XL

# RESEARCH OFFICER IMMUNOLOGY

A vacancy exists for a suitably qualified graduate to investigate biophysical aspects of white cell interactions with specific and nonspecific stimulants. A wide range of equipment is available to study various aspects of cellular response and an innovative approach will be required to develop a new research programme in association with existing flurorescent techniques. A physical or biological background is desirable since the emphasis will be on a physical approach to biologically orientated phenomena.

The post will last for an initial period of three years with salary dependent upon qualifications but in the range £5,285 to £7,700 per annum.

Further details may be obtained from Dr J A V Pritchard, Head, Immunology Department, Velindre Hospital, Whitchurch, Cardiff CF4 7XL, Tel: 615888.

Application forms (quoting ref No R30) obtainable from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN. Tel. No. 0222/755944 ext 2296. (030)A

# UNIVERSITY OF THE WEST INDIES

Jamaica

Applications are invited for two post of

# PROFESSOR/SENIOR LECTURER IN PHYSICS

One appointment will be made in the field of Materials Science. The appointee is expected to continue to shape and teach undergraduate as well as (projected) graduate courses; the person appointed will also be expected to lead in the further development of research in the area of Materials Science. Industrial experience will be an advantage.

The other appointment should be in one of the following fields: Atmospheric Physics; Radio Astronomy; Energy Studies; Materials Science (Metals and Fibres). The appointee is expected to consolidate and/or develop the research interests of the Department, especially the one(s) which coincide with his/her own interests. Salary scales: Professor J\$22,848 — J\$28,284 pa. Senior Lecturer J\$17,748 — J\$21,717 pa. (£1 sterling = J\$3.37). FSSU. Study and Travel Grant. Unfurnished accommodation or housing allowance. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 10 Spring Gardens, London SW1A 2BN. Further details are available from either address. (022)A

#### THE OPEN UNIVERSITY

# **Faculty of Science BIOLOGY ELECTRON** MICROSCOPE **TECHNICIAN**

The Science Faculty has a tenured vacancy in the Biology Discipline for an experienced Technician to maintain and operate the department's Electron Microscope facilities The unit consists of a Joel JEM 100S and a Philips 301 with ancillary equipment housed in a purpose built suite including a photographic darkroom. Thin sectioning equipment includes a Reichert OMU3 and a Reichert ultracut.

Access to scanning electron microscope facilities is also available.

This post offers an opportunity to a technician seeking a responsible position in a unit serving both the Teaching and Research needs of the Department.

Applicants should have an HNC or equivalent and 10-12 years' practical experience in Biological Electron Micrscopy.

Commencing salary will be within the Technician Grade VI scale £6,532 — £7,802 p.a.

Application forms and further particulars are available from the Assistant Secretary, Science (438/2), The Open University, Walton Hall, Milton Keynes, MK7 6AA or telephone Milton Keynes (0908) 653481: there is a 24 hour answering service on 653868.

Closing date for applications: 31st December.

### **UNIVERSITY OF** SOUTHAMPTON DEPARTMENT OF PHYSICS POST DOCTORAL RESEARCH **FELLOW**

Applications are invited from Physicists with interests in experimental high energy particle physics. The work involves the development and use of hardware for such experiments and also on-line and off-line computing which forms an important part of this activity. The Fellow will be joining a group which is involved in experimental work at CERN (Geneva) and will be expected to spend part of his/her time there. Starting salary will be in the range £6,070 — £7,700 per annum plus USS benefits

Applications (2 COPIES) should be sent to R A Dawson, Staffing Department, The University, Highfield, Southampton SO9 5NH with curriculum vitae and the names of referees quoting reference 2001/R/N. (045)A

# Research & Development diagnostic reagents

# Scientific and technical appointments

**BECKENHAM: KENT** 

Wellcome Reagents has an established place in the diagnostics market. The Reagents Research and Development team has a wide ranging brief, from the initial research and feasibility studies to final product development, and enjoys close liaison with specialist marketing and production colleagues. Collaboration with other scientific groups, participation in symposia and publications are important as part of the work of the department. As a result of continuing expansion we can offer challenging opportunities at both scientist and technician level.

# SCIENTIFIC APPOINTMENTS

Applications are invited from graduate and post doctoral scientists with at least 2-3 years working experience in either of the following areas:

## IMMUNOASSAY METHODOLOGY

with particular emphasis on radio immunoassay or related non isotopic techniques. A preference for the development and evaluation of methods, rather than simple experience of routine use, would be an advantage.

# CLINICAL BACTERIOLOGY

knowledge and experience in the field of medical microbiology and associated bacterial immunology is essential. Suitable candidates are likely to have spent part of their career in a

# TECHNICAL APPOINTMENTS

Suitable candidates will have some years' relevant laboratory experience of biochemical, immunochemical or immunoassay techniques. Formal education to HNC level is expected and opportunities will be available for further study where appropriate.

Salaries for all positions will reflect the experience and abilities of appointees. Excellent benefits include 5 weeks' holiday, subsidised restaurant, first class sports and social facilities and generous assistance with relocation expenses where appropriate.

For an application form please ring our automatic telephone answering service on 01-650 6541, giving your name and address and quoting reference number WRL/159. Alternatively please write to Miss A. Rountree, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3

# POSTDOCTORAL POSITIONS

Funded for 2 years are available immediately to study phospholipid metabolism in the cardiovascular system. The research will focus on the isolation, characterization, and regulation of cardiovascular phospholipases A2.

Salary: NIH guidelines.

Send résumé and three letters of reference to: Dr Richard C Franson, Department of Biophysics, Box 694, Medical College of Virginia, Richmond, Va. 23298.

An Equal Opportunity/Affirmative (NW147)A Action Employer.

The Faculty of Science of the University of Geneva is looking for candidates to fill a position of

# **PROFESSOR**

of general and/or cellular physiology, for the department of Animal Biology.

The successful candidate is expected to participate in teaching of general phisiology for biology students and to lead a strong research

Application: To be sent before 15 March, 1982 to: Faculté des Sciences, Université de Genève, 20, Quai Ernest Ansermet, CH-1211 Genève 4, Switzerland.

# Program Director, Immunology

Play a key role in advancing the field of *in-vitro* diagnostics.

The BBL Microbiology Systems Division of Becton Dickinson is the world leader in microbiology. Combine your scientific expertise with our recent state-of-the-art advances, and together we'll assume the same leadership position in the expanding area of in-vitro diagnostics.

You'll provide overall direction to our expanding Immunology department by managing existing projects and by assessing needs for new ones. Using a "systems approach" to management, you'll develop and monitor budgets, secure necessary external resources, develop detailed plans and schedules, etc.

You should possess a PhD or equivalent and formal training in immunology, virology, biochemistry, microbiology and/or cell biology. You should have working knowledge of the growth and isolation of microbial antigens, production of conventional and monoclonal antibodies, and biochemical and immunodiagnostic technologies. Scientific/industrial recognition as evidenced by publications, patents, etc., is required, as is a minimum of 8 years research experience including a supervisory background.

We offer an excellent salary and outstanding benefits. Find out more about the innovative environment and the career advantages of this expanding division of Becton Dickinson by sending résumé and salary history to: Dr. Laurance McCarthy, BBL Microbiology Systems, Becton Dickinson, Dept. 20D PO Box 243, Cockeysville, Maryland 21030. An equal opportunity/affirmative action employer.

Caring for people is our business

BECTON DICKINSON

(NW138)A

# UNIVERSITY OF THE WEST INDIES

Jamaica

Applications are invited for the following posts

#### 1 CHAIR IN COMPUTING SCIENCE

in the Department of Mathematics. Applicants will be expected to have wide interests and experience in Computing Science and to have done considerable research in Software Development and/or Applications.

2 GUINNESS RESEARCH FELLOW/JUNIOR RESEARCH FELLOW IN GEOLOGY

(Peat Studies) tenable for two years

Primary consideration will be given to persons who have a postgraduate qualification in a field related to peat science, particularly in palynology or palaeontology. Those with a suitable first degree will be considered at the Junior level. The appointee will be required to carry out stratigraphical and palaeontological investigations on the late Quaternary deposits of coastal wetlands in Jamaica. He/she will also expected to do a certain amount of lecturing and/or seminar work in related Quaternary geological topics to advanced undergraduate and postgraduate students, and to participate in setting up the research facilities necessary for the continuation of work in this field.

Salary Scales: Professor J\$22,848 — J\$28,284 pa. Research Fellow J\$15,090 — J\$20,049 pa. Junior Research Fellow J\$13,308 — J\$14,088 pa. (£1 sterling = J\$3.37). FSSU. Study and Travel Grant. Unfurnished accommodation or housing allowance. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 10 Spring Gardens, London SW1A 2BN. Further details are available from either address.

(023)A

### UNIVERSITY OF TEXAS

DEPARTMENT OF MICROBIOLOGY POSTDOCTORAL POSITIONS

Virologist, immunologist and experimental oncologist. Part of an active research program on interferons, lymphokines, cytokines, effector cells and anti-tumor agents.

Send C V and names and telephone numbers of three references to:

Dr Samuel Baron, Department of Microbiology, The University of Texas Medical Branch, Galveston, Texas 77550

An Equal Opportunity/ Affirmative Action Employer, M/F/H. (NW151)A

# THE LONDON HOSPITAL MEDICAL COLLEGE (University of London) Electron Microscope Unit DEPARTMENT OF ORAL PATHOLOGY SENIOR MLSO IN ELECTRON MICROSCOPY

A vacancy exists for an experienced microscopist in this busy and forward-looking unit. The unit is involved in a variety of research projects and has the most modern equipment for both transmission and scanning electron microscopy. Applicants should have full experience of preparative procedures for either or both techniques.

Salary will be at a point on the Whitley Council Senior Medical Laboratory Scientific Officer scale and applicants should have FIMLS, MI Biol or an equivalent qualification. Informal enquiries and appointments to visit the unit may be made by telephoning on 01-247 5454, ext 348.

Formal applications, quoting names of two referees, within fourteen days, to Professor N W Johnson, Department of Oral Pathology, The London Hospital Dental Institute, Turner Street, London El 2AD. (036)A

CELLULAR PHYSIOLOGIST urgently needed. Teaching and research experience emphasized. For partipation in current work on cell culture of transformed cells. Please apply to the Chairman, Physiology Department, Ponce School of Medicine, P.O. Box 7004, Ponce, PR 00732 U.S.A. (NW150)A

# THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments are usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

## CCD Detector Development MOUNT WILSON AND LAS CAMPANAS OBSERVATORIES

# CARNEGIE INSTITUTION OF WASHINGTON

The Observatories are seeking a person with experience in detector development to participate in the construction of multiple-CCD imaging systems for large-area, multi-color photometric measurements. The detector systems will be assembled at the Observatories' headquaters in Pasadena, California, and installed on Carnegie telescopes at Palomar Mountain, California and Cerro Las Campanas, Chile. Participants in the development effort will have the opportunity to engage in research programs using the completed instruments.

Applicants should have an educational background in either astronomy, physics, or electronics, with some experience in detector development and computer data acquisition. The position could be suitable for a scientist seeking postdoctoral experience or for an instrumentation professional.

Interested persons should send résumés to:

Dr. Stephen A. Shectman, Mount Wilson and Las Campanas Observatories, 813 Santa Barbara Street, Pasadena, CA 91101-1292, U.S.A.

The closing date for the receipt of applications for this position is January 15, 1982.

The Carnegie Institution of Washington is an Equal Opportunity Employer, M/F/H. (NW139)A

# UNIVERSITY OF LEICESTER DEPARTMENT OF GENETICS POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from persons with a good background in biochemistry or molecular genetics for a postdoctoral research position financed by a Cancer Research Campaign award. The project will be concerned with the characterisation of error-prone DNA replication in *E. coli* induced by carcinogens or UV-irradiation. This will involve the use of cloning teachniques, in vitro DNA replication systems and enzyme purification procedures. The work is likely to involve close collaboration with research groups in the Department studying other aspects of the SOS response in *E. coli* and with groups studying the control of and mechanism of plasmid DNA systhesis using an in vitro system.

The appointment will be tenable for up to 3 years from 1 January 1982 or as soon after as can be arranged. Starting salary £6,880 (at age 26) per annum with full superannuation provision.

Applications with names of two referees to Dr I B Holland, Department of Genetics, University of Leicester, Leicester LE1 7RH.

(043)A

# **ORGANIC CHEMISTS**

# -for Medical Products Development £8500-£9000

We need skilled and imaginative Organic Chemists to play key roles in our development programme for new medical products.

Our diagnostic kits are already well established in the Obstetrics, Thyroid and Haematology fields and make a substantial and growing contribution to our turnover worldwide. The opportunities for further growth are considerable and these posts require innovative Organic Chemists who, as members of multi-disciplinary development teams, can take responsibility for the design and preparation of novel compounds for incorporation into proposed clinical assay kits.

Candidates must be qualified to PhD level in Organic Chemistry or have equivalent experience. The posts offer considerable scope for scientists keen to join a rapidly expanding, high technology organisation.

Starting salaries will be around £8500 - £9000. Conditions of employment are excellent and assistance with relocation will be given where appropriate.

In the first instance, please write with full career details to P. L. Jones, Personnel Manager, at the address below:

# **Amersham International Limited**

White Lion Road Amersham Buckinghamshire HP7 9LL

(052) A

# MEDICAL RESEARCH COUNCIL DIVISION OF VIROLOGY NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for a short term staff appointment with tenure for 3-5 years to join a small team engaged in morbillivirus research. The work currently involves exploiting recombinant DNA techniques and the successful applicant will be expected to develop this approach. Experience in biochemical, virological and/or recombinant DNA technology at a post-doctoral level would be desirable.

Salary will be dependent on age and experience and will fall within the range £7290-£8925 plus £967 London allowance and superannuation provision. Further information may be obtained from Dr W C Russell (01-959 3666 Ext 273).

Applications should be submitted to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA by the 1st February 1982 together with Curriculum vitae and the names of two professional referees. Please quote reference V1/LH. (040)A

# Senior Research Microbiologist

Cutter Laboratories, Inc., the world leader in plasma fractionation, and manufacturer of a broad range of medical and biological products for international health-care markets, seeks a Senior Research Microbiologist to head a research team to investigate the use of monoclonal antibodies for therapy. The research facilities are housed in a brand-new multimillion dollar building.

This position requires the knowledge ordinarily acquired from post-doctoral research in Microbiology and Immunology or an equivalent combination of education and experience. The successful candidate must have demonstrated ability to carry out independent and innovative research in the field of monoclonal antibodies, and possess a good knowledge of cellular immunity.

Cutter Laboratories is located in Berkeley, California, which is part of the very cosmopolitan San Francisco Bay Area. Within this area are also located the Berkeley and San Francisco campuses of the University of California.

Cutter Laboratories offers excellent salaries, competitive with comparable positions in this area, along with attractive fringe benefits.

Please send detailed resume to Corporate Employment Department, PO Box 1986, Berkeley, CA 94701. An equal opportunity/affirmative action employer.

CUTTER Laboratories, Inc.

(NW148)A

# THE SPACE SCIENCE DEPARTMENT

of the

## **EUROPEAN SPACE AGENCY**

seeks

#### **SCIENTISTS**

for

## **EXOSAT OPERATIONS**

Applications are invited from young scientists holding postdoctoral or equivalent qualifications in astronomy or physics and having experience with scientific instrumentation and data analysis (preferably related to space research) to act as duty scientists in the operation of the European X-Ray Observatory Satellite EXOSAT.

Duties include evaluation of the feasibility of observation proposals, establishment of observation programmes, liaison with observers, conduct of observations and preliminary data analysis. The scientists will have the opportunity of undertaking their own observation programmes in X-Ray astronomy.

Prior to launch the scientists will be located at ESA's Space Science Department ESTEC in the Netherlands, transferring to ESOC, Darmstadt in Germany for orbital operations.

Please send detailed curriculum vitae to the Head of Personnel ESTEC, Postbus 299, 2200 AG Noordwijk, the Netherlands.

(W532)A

# UNIVERSITY OF GIESSEN Faculty of Biology

# **HEAD OF MICROBIOLOGY**

Applications from German speaking individuals are invited for the position of a full PROFESSORSHIP (C4). The successful applicant is expected to direct teaching of biology students in microbiology and should have demonstrated research excellence in the area of gene expression and gene regulation including experience in recombinant DNA methodology.

Applications should be received before 5th of January 1982, and should include curriculum vitae, list of publications, account of teaching experience and the names of three referees. The position will become available in the summer of 1982. Applications should be addressed to:

President, University Glessen, Postfach 111 440, D-6399 Glessen, Federal Republic of Germany

(W525)A

# Scientists for Condensed Matter Studies at Rutherford Appleton Laboratory

The Rutherford Appleton Laboratory is constructing a new neutron source, known as the Spallation Neutron Source (SNS) which will provide intense pulsed neutron beams for condensed matter research by scientists from universities and polytechnics. This is a major project of world significance which is planned for initial operation by 1984.

Preparation for exploitation of the SNS has begun, and requires progressive recruitment of neutron scattering scientists to support the neutron scattering experimental programme, and theoretical scientists to work with the associated condensed matter theory group led by Dr S W Lovesey. Neutron scattering specialists will contribute to the design of instruments, supervision of their operation, planning of support facilities, and collaboration with external university scientists. The work of the theory group is presently directed to the static and dynamic properties of localised magnets, electron motion and correlations in metals and semiconductors, liquid crystals and phase transitions, and the dynamic properties of simple liquids and macromolecular systems. Staff are encouraged to participate in scientific research projects, usually in collaboration with the user community, and using facilities at Harwell and the Institute Laue – Langevin (ILL) Grenoble.

At present the Laboratory is able to offer two permanent posts at SO/HSO level. There is also scope for fixed term appointments and joint appointments with universities. Applications are invited from suitable qualified scientists, both experimental and theoretical, who have already demonstrated their ability in condensed matter research.

Salary scales:

Scientific Officer £5176-£6964 Higher Scientific Officer £6530-£8589

For further details and an application form, contact the Personnel Group on Abingdon (0235) 21900 quoting reference VN02 or write to the Personnel Group, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon. OX11 0QX.

Closing date for applications: 6th January, 1982.

Appleton	In the forefront
Laboratory	of research

# UNIVERSITY OF EDINBURGH DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOW (Crystallography)

Applications are invited for the above SRC-funded post to investigate the crystal structures of some simple volatile inorganic compounds.

Applicants should have experience in X-Ray Crystallography. Familiarity with techniques of low temperature crystal preparation would be an advantage.

The appointment will be for two years starting on or after 1st April 1982. The initial placing will be on the 1A scale, starting at a point that will depend on age and qualifications.

Applications, including the names of two referees, should be sent to Professor E A V Ebsworth or Dr A J Welch, Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh EH9 3JJ, from whom future particulars may be obtained. Please quote reference 5049. (029)A

# UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY

Applications are invited from candidates with a good honours degree in Biology, Microbiology or Public Health Engineering for a post of

## RESEARCH ASSISTANT

in the above Department for a fixed period of three years commencing not later than 1st March 1982. The successful candidate will work on an SERC funded research project on the treatment of domestic sewage in waste stabilization ponds in warm European climates and will be expected to do up to two months fieldwork each year in Lisbon, Portugal.

Initial salary within the range £5,285 — £6,070 per annum.

Applications, together with the names of three referees, should be received not later than 5th January, 1982, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/912/N. (025)A

# UNIVERSITY OF THE WITWATERSRAND

Johannesburg

DEPARTMENT OF PHYSIOLOGY

Applications are invited from suitably qualified persons, regardless of sex, religion, race, colour or national origin, for appointment to the posts of: SENIOR

## LECTURER/LECTURER

Applicants for these posts should have a medical or veterinary degree or a PhD in Physiology, Biochemistry, Zoology or any other biological field.

The Lectureships and Senior Lectureships involve teaching undergraduate and graduate Medical and Science students, research, and participation in the administrative work of the department. There is no restriction on the field of interest of applicants.

The salary range for Lecturer is R10,995 — R19,230 and for Senior Lecturer is R14,370 — R20,850 per annum

Intending applicants are requested to obtain copies of the information sheet relating to these vacancies from the Director, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE (quoting ref 11/1/698), or from the Director: Personnel Office, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001, South Africa, with whom applications should be lodged by 31 December 1981, or as soon thereafter as possible.

(032)A

# Professor of Mechanical Engineering Royal Military College of Science

Applications are invited for the permanent post of Professor and Head of the Department of Mechanical Engineering. The Department, with 24 teaching and 70 supporting staff, is responsible for the CNAA BSc courses in Military Vehicle Technology, Guided Weapons, and Gun Systems, Design. There are branches in Applied Thermodynamics, Applied Mechanics and Mechanical Design, each headed by an Associate Professor.

The College runs first degree, post-graduate, army staff and special courses on a wide variety of subjects. While its primary function is the scientific education of army officers, the student population includes civilians, and military personnel from overseas. It is a residential establishment occupying a large estate in the Vale of the White Horse, near Swindon, and has an academic staff of over a hundred. There are

extensive laboratories and workshops; and research is encouraged, and supported by a variety of outside sponsors. The role of the college is being reviewed. The successful applicant will be required to take part in implementing any changes that are decided by the Army Board.

Applicants should be Mechanical Engineers of distinction and achievement, preferably with experience of teaching at university level.

Starting salary (according to qualifications and experience) within the range £17,685 – £20,895.

For further details and an application form (to be returned by 8 January 1982) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref:* S/5673/5. (038)A

# UNIVERSITY OF CAPE TOWN ASSOCIATE PROFESSOR OR SENIOR LECTURER IN GENETICS

Applications are invited for the above post in the Department of Biochemistry. Appointment, according to qualifications and experience, will be made on the salary scale:

Senior Lecturer: R14,370  $\times$  810-R20,850 pa. Associate Professor: R18,420  $\times$  810-R20,850  $\times$  900-R22,650 pa. In addition a service bonus of nearly one month's salary is payable annually.

Candidates should have strong research interest in eucaryotic molecular genetics and experience in recombinant DNA technology and assume duties during the first half of 1982. Candidates should state for which post they wish to be considered.

The post may also be filled at the request of the applicant on a contract basis for 2-3 years with either the possibility of renewal or conversion into a tenured post.

Applicants should submit curriculum vitae, stating present salary, research interest and publications, when available if appointed, and the names and addresses of three referees.

Further information should be obtained from The Registrar (Attention Appointments Officer) University of Cape Town, Rondebosch, 7700 South Africa to whom applications (Quoting reference No AC/11) must be submitted as soon as possible.

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information ont he implementation of this policy is obtainable from the Registrar. (W518)A

# UNIVERSITY OF BIRMINGHAM

# **DEPARTMENT OF PHYSICS**

The Department of Physics has a limited number of places for suitably highly qualified overseas students wishing to undertake postgraduate work to MSc or PhD level. Candidates should be in the top 15% of their degree class and have, or expect to get, the equivalent of a top honours degree. Selected candidates will be nominated for the U.K. Government Fee Support awards.

The Physics fields of interest include

# CONDENSED MATTER NUCLEAR STRUCTURE ELEMENTARY PARTICLES and APPLIED NUCLEAR SCIENCE

For full details of the research activities and related MSc courses, and for application forms please write to

Dr. Malcolm C. Scott Department of Physics University of Birmingham P.O. Box 363 Birmingham B15 2TT, England.

(027)A

#### UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

#### LECTURESHIP/SENIOR LECTURESHIP **DEPARTMENT OF LAND MANAGEMENT** (Available 1st March, 1982)

Applicants must have a degree in Soil Science with major qualifications in either Soil Chemistry or Soil Physics. Experience in teaching and research would be an advantage.

### LECTURERSHIP/SENIOR LECTURESHIP **DEPARTMENT OF CLINICAL PHARMACOLOGY** (2 posts) (available immediately)

Applicants must have a medical qualification with a specialist diploma such as MRCP or equivalent. The successful applicant will be required to teach Pharmacology and Clinical Pharmacology to Medical and Pharmacy students, and to assist in the management of General Medical wards.

#### LECTURESHIP/SENIOR LECTURESHIP DEPARTMENT OF MEDICAL MICROBIOLOGY (Available 1st March, 1982)

The successful applicant should preferably have experience in all fields of medical microbiology but an interest in virology would be an advantage. Duties would include lecturing to Medical Pharmacy and para-medical students and also to supervise the day-to-day running of the diagnostic virology unit situated in the Department.

#### LECTURESHIP/SENIOR LECTURESHIP **DIVISION OF BIOLOGICAL SCIENCES** (BIOMATHEMATICS) (Available 1st March, 1982)

A Biomathematician required with experience in the teaching of statistical and analytical methods as well as in the mathematical modelling of natural systems to each courses at undergraduate and postgraduate levels and to advise on the design and analysis of research carried out by students and staff in the Division of Biological Sciences.

#### SCIENTIFIC DIRECTOR UNIVERSITY LAKE KARIBA RESEARCH STATION **DIVISION OF BIOLOGICAL SCIENCES** (Available 1st March, 1982)

Applicants should be scientists with an established record of leadership and personal research achievement in the study of aquatic ecosystems to lead a team of mainly post-doctoral research fellows based at Kariba which will investigate the Lake Kariba system, the probable initial emphasis of this research being on primary production and nutrient

## LECTURESHIP/SENIOR LECTURESHIP **DEPARTMENT OF BOTANY** (Available immediately)

The successful applicant, who must have a suitable doctorate, will be expected to contribute to courses in general and applied microbiology at both undergraduate and postgraduate degree level. Preference will be given to candidates with research experience in applied or environmental bacteriology.

Salary Scales (approx. Stg. equivs.):

Non-Medical — Academic Staff Lecturer Grade II: £5,046 × 363 — £6,861 × 380 — £8,761 Lecturer Grade II: £9,158 × 380 — £10,679 Senior Lecturer: £10,109 × 380 — £11,249 × 389 — £13,194

Medical - Academic Staff

Medical — Academic Starr
Assistant Lecturer:£7,551 × 311 — £8,795
Lecturer Grade II: £9,910 × 371 — £12,139
Lecturer Grade II: £12,519 × 380 — £14,040
Senior Lecturer: £14,472 × 432 — £16,200 × 363 — £16,563

Appointment on the above scales according to qualifications and experience.

Conditions of Appointment: Both permanent pensionable terms and short-term contracts are offered for academic posts.

Further Particulars on conditions of service and on method of application should be obtained prior to submitting an application from application should be obtained plant to director, Appointments and Personnel, University of Zimbabwe, PO Roy MP 167 Mount Pleasant, Salisbury, Zimbabwe, or the Box MP, 167, Mount Pleasant, Salisbury, Zimbab Association of Commonwealth Universities (Appts.), Square, London WC1H 0PF.

Closing date for receipt of applications is 31 January 1982.

# I.L.R.A.D. (Nairobi)

Applications are invited from suitably qualified candidates for the post of:

# POST DOCTORAL FELLOW Ref No PDF/L4/81/1

A position is available for a post-doctoral fellow to work with the Immunobiology Unit on the definition of cells of the bovine immune system. Applicants must have experience in preparing, maintaining and testing, functional T-cell, natural killer cell etc., clones from a mammal.

The successful applicant will be expected to work closely with other members of the unit who have produced monoclonal antibodies against bovine B-cell T-cell and macrophage surface membrane determinants. The studies are directed towards understanding bovine immune response against African trypanosomes and Theileria infected bovine cells. This is an international position, the salary will be paid in U.S.\$ and the successful applicant will be assisted with moving expenses

Applications identified with Ref No including C.V., summary of PhD thesis, and three references should be sent to:

> Chief Personnel Officer, I.L.R.A.D P.O. Box 30709, NAIROBI, Kenya

Closing date: 7/1/82

(W528) A

#### UNIVERSITY OF ARIZONA DEPARTMENT OF CHEMISTRY

ACADEMIC POSITION

Invites applications for a possible tenure-track position at the Assistant Professor level in one of the following areas: (1) Synthetic Solid State Chemistry; (2) Surface Chemistry; and (3) Atmospheric or Low-Temperature Geochemistry.

Candidates should have demonstrated in their Ph D and/or postdoctoral work the ability to develop a vigorous and innovative research program in one or more of the above areas and have a commitment to instructional excellence.

résumé brief description of research plans, and three letters of recommendation should be sent to Professor William S Glaunsinger, Chairman, Search Committee, Department of Chemistry, Arizona State University, 85287. EO/AA employer. (NW146)A State University, Tempe, Arizona

#### UNIVERSITY OF OXFORD DEPARTMENT OF ZOOLOGY DEPARTMENTAL **DEMONSTRATORS**

Applications are invited for two demonstratorships, the holders of which will be required to assist in the teaching work of the department, particularly the Animal Kingdom course. One post will be primarily concerned with the invertebrate part of the course and this will be available for 1st October 1982. The other is concerned with the vertebrate course and should be taken up in January 1982 or as soon as possible afterwards. The posts are tenable for years and may be renewed for one further period; the salary scale is £8,105 £5.285 -

Candidates, who should be of post-doctoral level, should send their applications with the names of two referees and a clear indication of their preference and availability for the wo posts to the Linacre Professor, Department of Zoology, South Parks Road, Oxford by 5th January.

(046)A

# UNIVERSITY OF CAPE TOWN

**Department of Organic Chemistry** 

# Postdoctoral or Post MSc **Research Fellowship**

A Fellowship is available at either the postdoctoral or post MSc level for research in organic chemical synthesis, with emphasis on aromatic, quinonoid, and heterocyclic systems of potential medicinal interest. The position will be available for one year in the first instance, and renewable for a further two years.

Salary ranges: Postdoctoral R10 935 - 13 410 Post MSc R8 730 - R11 430

A contribution to relocation expenses may be made for overseas appointees. Further information may be obtained from Associate Professor R.G.F. Giles, Department of Organic Chemistry, University of Cape Town, Rondebosch, 7700, South Africa, to whom applications, with the names of two referees should be sent as soon as possible.

# **EXCHANGE CAPITAL FOR IDEAS**

# IN BIOLOGICAL OR CHEMICAL COMPOUNDS

We are not a pharmaceutical firm but a Swiss-based, independent financial group which is prepared to let you participate in a capital venture for the exploitation of your project.

In 1981, we have examined more than 400 projects.

Our object: the development of new biological or chemical products with previous pharmacological screening up to the stage of clinical tolerance and efficacy required to permit licensing negotiations.

To obtain all the information required for initial selection, please write in English, French or German to: DEBIOPHARM S.A. Petit-Chêne 38 - 1001 LAUSANNE (Switzerland).

(W527)A

#### CARLETON UNIVERSITY DEPARTMENT OF GEOLOGY

# Invites applications for the position of RESEARCH ASSOCIATE

with responsibility for the electron microprobe laboratory.

Candidates should have appropriate background to work with the department's Cambridge MKV mciroprobe, Ortec EDS, Data General Nova 2 computer, PESTRIP-4 and EDDATA data handling programs and the University's Honeywell CP-6 computer. This is a two-year position with the possibility of renewal.

Send curriculum vitae and the names of three referees before January 15, 1982 to J A Donaldson, Chairman, Department of Geology, Carleton University, Ottawa, Ontario K1S 5B6 Canada.

(NW144)A

# UNIVERSITY COLLEGE DEPARTMENT OF PATHOLOGY POST DOCTORAL

# RESEARCH POSITION

Post doctoral research position under the National Board for Science and Technology "Higher Education Industry Cooperation" scheme commencing January-February 1982. Project entitled "Pharmaceutical applications of monoclonal antibodies". Experience of tissue culture techniques essential.

Salary will be commensurate with qualifications and experience up to IR£7,500. Project is funded for 3 years.

Send Curriculum Vitae with the names and addresses of two referees to Dr H McLaughlin, Dept of Pathology, University College, Earlsfort Tce, Dublin 2, to arrive before December 21st 1981.

(037)A

# ROSENSTIEL SCHOOL OF MARINE AND ATMOSPHERIC SCIENCE

# University of Miami

Tenure track position in Fisheries Science in Division of Biology and Living Resources: Assistant Professor to Professor; salary and rank dependent on qualifications and experience; starting date 1 June 1982 or as soon as possible thereafter.

or as soon as possible thereafter.

Applicants should hold Ph.D. in fisheries or appropriate related field. Experience desirable in one or more of following areas: a) stock assessment and management; b) tropical, multi-species fisheries; c) larval fish ecology; d) predator-prey relationships. Incumbent expected to develop field and laboratory research including independent research proposals and would be responsible for teaching graduate courses "Introduction to Fisheries Science" and "Biometrics" and development of new courses in area of specialization as required. The candidate would be encouraged to initiate or participate in fisheries projects overseas.

Applications should include curriculum vitae, a brief statement of research interests and objectives and names of three referees and be forwarded to:

Dr. F. Williams, Chairman, Search Committee, Division of Biology and Living Resources, Rosenstiel School of Marine and Atmospheric Science, 4600 Rickenbacker Causeway, Miami, Florida 33149.

Closing date for applications 19 February 1982.

The University of Miami is an Affirmative Action/Equal Opportunity Employer. (NW143)A

# CSIRO AUSTRALIA Research Fellow (Cellular Biology)

\$A19,662 — \$A28,564 pa Molecular & Cellular Biology Unit North Ryde, New South Wales

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,500 employees — 2,700 of whom are research and professional scientists — located in divisions and sections throughout Australia.

**General:** The Unit's work includes research programs on animal cell growth and development, DNA maintenance and modification and gene technology.

**Duties:** As a member of the growth and development group, to carry out research on Cellular Differentiation, particularly on the mechanisms of action of specific differentiation factors.

Qualifications: A PhD, or equivalent, in biological sciences, with basic training in some aspects of molecular biology. Experience with tissue culture techniques is essential.

Tenure: Four years, superannuation benefits available.

Applications: In writing and stating full personal and professional details, the names of at least two referees and quoting reference No A0506 should reach: The Officer-in-Charge, Molecular & Cellular Biology Unit, CSIRO, PO Box 184, NORTH RYDE, NSW 2113, AUSTRALIA by 8 January 1982. (047)A

## Rijksuniversiteit Utrecht

State University of Utrecht, Netherlands

The Department of Geology and Geophysics of the State University of Utrecht, The Netherlands invites applications for the position of

# **Professor in Meteorology**

Applicants will be responsible for the teaching of meteorology. The candidate will also be expected to participate in and encourage research, and to contribute to national and international coordination in the field of meteorology.

Preference will be given to atmosphere scientists or physicists with a scientific qualification and interest in geophysical fluid dynamics.

Candidates should be willing to learn to lecture in Dutch within two years. Salary is to a maximum of Dfl. 10.844, — per month, depending on age and experience.

Applications, including a curriculim vitae and list of publications, should be directed, within 4 weeks upon publication of this journal, to the application board, Instituut voor Meteorologie en Oceanografie, Princetonplein 5, 3584 CC Utrecht, Netherlands.

Further information can be provided there. Tel: 030-533275. (W530)A

# Scientific Specialists I Microbiology I Immuno-diagnostics Our client is the Diagnostics Division of one of the world's leading health care companies, with an outstanding range of diagnostic products in the forefront of technology.

- forefront of technology.
- These two opportunities are based at European headquarters in Wiesbaden, Germany, and provide technical services, R & D activity and scientific advice within an international marketing group. Considerable travel throughout Europe and elsewhere will be involved.
- Candidates should have a PhD degree or equivalent, with appropriate laboratory experience either in microbiology or clinical chemistry/immuno diagnostics depending on the appointment. A multi-lingual capability in English and French or German essential. A good scientific background with a commercial awareness is required.
- Salaries and benefits are very attractive. Opportunities for further promotion are genuinely interesting.

Send a cv to J F Fulford, Grosvenor Stewart, 207-209 Avenue Louise, 5th Floor, Box 8, 1050 Brussels; or 117 George Street, London W.1; or telephone Belgium (02) 6400796 or UK (0462) 55303.

**UNIVERSITY OF EDINBURGH** DEPARTMENT OF **HUMAN GENETICS** 

#### RESEARCH ASSOCIATE/ **POST-DOCTORAL FELLOW**

Applications are invited for the above post, funded by the cystic fibrosis research trust and tenable from 1st March 1982 for 18 months in the first instance. Candidates should be capable of establishing and maintaining a laboratory for culture of human fibroblasts. Experience in hybridoma technology would be an advantage.

Starting salary at an appropriate point according to qualifications, age and experience on either scale 1A for post-doctoral fellows (£6070-10575) or scale 1B (£5285-7700). Curriculum vitae should be sent as soon as possible to Dr D J H Brock, Depart-ment of Human Genetics, Western General Hospital, Edinburgh 4., from whom further particulars can be obtained (031-332 2471). Please quote reference 5069. (042)A

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S **HOSPITAL** 

(University of London) West Smithfield, London EC1A 7BE

#### POST DOCTORAL RESEARCH FELLOW

required in Department of Haematology for Cancer Research Campaign grant entitled "Isolation and Characterisation of regulatory variants for the expression of murine lymphocyte cell surface antigens". Experience in cell membrane biochemistry necessary and immunology/cell culture experience desirable. The post is tenable for three years from 1 January 1982, or soon after. Salary on Scale £6,070 — £10,575 plus £967 LA.

Apply in writing with CV and names of two referees to The Secretary of the College at the above address, quoting ref 925. Further information from Dr M A Horton Tel: 01-600 9000 exten-(021)Asion 3272.

IMPERIAL COLLEGE University of London **POSTDOCTORAL** RESEARCH ASSISTANT IN

## PHYSICAL CHEMISTRY

Required to develop electro-chemical sensors for real time trace element analysis of seawaters. A background in electroanalytical chemistry and micro-computer techniques would be advantageous. The appointment is for one year in the first instance. Salary up to £7,874 (inc L/A). Start as soon as possible.

Apply with cv and names of two referees to Professor W J Albery, Department of Chemistry, Imperial College, London SW7 2AY.

(050)A

#### ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

#### RESEARCH ASSISTANT

required to work on the biochemistry of human cardiac valves. The project will involve techniques in protein separation and cell culture and applicants should have a good honours degree in Biochemistry or a nonours degree in Biochemistry or a related discipline. The appointment is funded by the Jenson Research Foundation, available from 1 March 1982 and for 1 year initially renewable for up to 3 years. Initial salary up to £7044 p.a. There may be an opportunity to register for a higher degree with the University degree with the University.

particulars Further application form available from the Establishments Officer, St George's Hospital Medical School, Cranmer Terrace, London SW170RE.

#### UNIVERSITY OF OXFORD DEPARTMENT OF GEOLOGY AND MINERALOGY POST-DOCTORAL

RESEARCH ASSISTANT A Research Assistantship is available for three years, from 1 January 1982. for a geochemist with a strong background in physical chemistry or a physical chemist with interests in geology to assist in the measurement of the thermodynamic properties of silicate melts and minerals by high temperature Knudsen Cell mass spectrometry. The research is in col-laboration with the Max-Planck-Institut für Chemie in Mainz, W Germany and will involve approximately three months work per year in Germany.

Salary £6880 - £7700 plus living expenses in Germany.

Applicants should Curriculum Vitae and two letters of recommendation to Dr D G Fraser, Department of Geology and Mineralogy, University of Oxford, Parks Road, Oxford, OX1 3PR.

(041)A

# UNIVERSITY OF NORTH CAROLINA DEPARTMENT OF BIOCHEMISTRY

#### RESEARCH ASSISTANT **PROFESSOR** PhD contingent upon funds,

develop the research and training program in regulation of expression of genes involved in DNA repair, particularly to study the genes for the enzymes involved and their control. Postdoctoral training required.

Send CV and 3 letters of reference to: Nancy Nye, Dept of Biochemistry, School of Medicine, University of North Carolina, Chapel Hill, NC 27514.

We are keenly interested in attractwe are keenly interested in attracting outstanding women and/or minority scientists to this department. EQUAL OPPORT-UNITY/AFFIRMATIVE ACTION EMPLOYER. (NW145)A

#### **UNIVERSITY OF** WISCONSIN

DEPARTMENT OF METEOROLOGY

#### POSTDOCTORAL PROJECT **ASSOCIATE**

Position available to participate in observational and theoretical studies of Arctic stratus clouds and related problems in Arctic meteorology.

Research includes analysis and interpretation of meteorological and radiometric data from aircraft field programs, and related modelling studies and parameterization development. 1-3 years duration. Start approximately 1 February 1982.

Salary commensurate with experience and qualifications. Ph D in meteorology, physics or related fields. Send vitae and names of three references to GF Herman, Meteorology, University of Wisconsin, Madison, WI 53706 by 20 January 1982. An Equal Opportunity (NW152)A Employer.

#### SIMON FRASER UNIVERSITY

Burnaby, British Columbia, Canada

DEPARTMENT OF BIOLOGICAL **SCIENCES** 

#### **ENVIRONMENTAL** TOXICOLOGY

Applications are invited for two tenure-track positions, one at the Assistant Professor level and one at the Associate Professor level. The successful applicants will teach undergraduate courses in En-vironmental Toxicology and graduate courses in Industrial Toxicology and Food and Drug Toxicology. Candidates must have a PhD degree with experience in toxicology and a strong record in research. The successful applicants will be expected to develop and maintain an active research programme in an area of toxicology appropriate to a Life Sciences department. Preference will be given to candidates eligible for employment in Canada at the time of application.

The positions are available from 1 September 1982 subject to budgetary constraints. The current salary base for the Assistant and Associate Professor ranks are \$25,000 and \$31,600/yr respectively.

Applications should include a curriculum vitae, a brief statement of research interests and objectives, and selected reprints of published research. Applicants should request confidential assessments of their research and teaching ability from three referees, to be forwarded directly to: Dr K K Nair, Chairman, Dept of Biological Sciences, Simon Fraser University, Burnaby, BC, Canada V5A 1S6.

Dealine for receipt of applications is 31 January 1982, or until the positions are filled. (NW129)A

### CONFERENCES and **COURSES**

#### UNIVERSITY OF BRISTOL

12 MONTHS M Sc COURSES BY ADVANCED STUDY AND RESEARCH are offered in the following

subjects:
Advanced Analytical Chemistry (Inorganic Chemistry) Surface Chemistry and Colloids (Physical Chemistry) The Physics of Materials (Physics) Mathematical Logic and Foundations of Mathematics (Mathematics) Fluid Mechanics (Mathematics)

Meat Science (School of Veterinary Science, Langford)

All six courses qualify for SERC studentships. Early application is fesirable. Further details of the ndividual courses may be obtained rom the Head of Department concerned, University of Bristol BS8 TH. Enquiries are also invited for letails of opportunities for research eading to the degree of PhD.

**UNIVERSITY OF SURREY** DEPARTMENT OF BIOCHEMISTRY **MSc IN TOXICOLOGY** 

Applications are invited for a postgraduate course leading to an MSc degree in toxicology. The course, which may be attended either fulltime or part-time is organised by the Department of Biochemistry, University of Surrey, with the MRC Toxicology Unit, Carshalton; the British Industrial Biological Research Association, Carshalton and Shell Toxicology (Tunstall) Laboratory, Sittingbourne. During the course instruction is given in these collaborative laboratories as well as at other major toxicological institutions. Entrance requirements are as for a PhD and a limited number of grants from the Medical Research Council and the Inveresk Research Foundation are available for suitable candidates. On the successful completion of the course opportunities may be available for students to register for a PhD in toxicology, and to undertake a period of research training in one of the above named organisations or in other laboratories approved by the University as being suitable for toxicology research.

The Medical Research Council, the Royal Society and the Royal College of Pathology have identified toxicology as a priority area for research training and therefore support the encouragement of first class students from a variety of disciplines to become involved in the science of toxicology. In modern society contact with potentially toxic chemicals is increasing. Problems may arise from the use of drugs for medical purposes. from occupational exposure to industrial products or intermediates and from environmental exposure to natural or

synthetic substances.

The course, which was the first of its kind in Europe, is designed to provide graduates in science, and medical and veterinary graduates, with an understanding and appreciation of the many disciplines involved in toxicology. Particular emphasis is placed on aspects related to the biochemical mechanisms of chemically-induced toxicity, and the assessment of toxicological hazard in the manufacture, use and disposal of new chemical compounds, pesticides and medicines. The course provides a broad biological education and is a suitable introduction for those intending to undertake research on the interaction of chemicals with biological systems.

There are numerous interesting opportunities for scientists, educated initially in different disciplines, who have acquired additional knowledge of toxicology. These may be in industry, government regulatory bodies, or research institutes with good career prospects in both laboratory work and administration.

Further information and application forms to be returned by either 1st March, 1982, (British and EEC applicants) or 1st June 1982 (Overseas applicants), can be obtained from: Dr R S Jones, Department of Biochemistry, University of Surrey, Guildford, Surrey GU2 5XH. (026)C

# **GULBENKIAN INSTITUTE OF** SCIENCE, PORTUGAL

## **During 1982 the following advanced** courses will be offered:

Electron Transfer Proteins, 21 June-2 July, J. Le Gall (Univ. Georgia), A.V. Xavier, J.J.G. Moura (New Univ. Lisbon), Larry C. Sieker (Univ. Washington).

The Biology of Human Social Relations, 19 July-30 July, Lionel Tiger, Robin Fox (Rutgers Univ.), James Chisholm (Univ. New

Effects of Alcohols and Other Membrane-Active Drugs on Yeast and Other Microorganism, 30 August-10 September, Anthony H. Rose (Univ. Bath), L.O. Ingram (Univ. Florida), Vitor M.C. Madeira (Univ. Coimbra), N. van Uden (Gulbenkian Inst.

Comparative Historical Sociology, 20 September 1 October, Richard M. Smith (Cambridge Group Hist, Pop. & Soc. Structure), Robert Rowland (Gulbenkian Inst. Sci.).

Taxonomy and Identification of Yeasts, 20 September-15 October, N.J.W. Kreger-van Rij (Univ. Groningen), C.P. Kurtzman (NRRC, Peoria, III.), J. Fell (Univ. Miami), S.A. Meyer (Georgia State Univ.).

Somatic Cell Genetics, 25 October-5 November, C. Thomas Caskey, David Konecki (Baylor Coll. Med., Houston), István Raskó (Biol. Res. Center, Szeged, Hungary).

Information and Registration Forms from: Professor N. van Uden, Gulbenkian Institute of Science, 2781 Oeiras Codex, Portugal.

#### **LECTURES**

# NATO ADVANCED STUDY INSTITUTE

# The Application of Laser Light Scattering to the Study of Biological Motion

20 June - 3 July 1982, Maratea, Italy

Speakers: N.S. Allen, R.D. Allen (Dartmouth), J.P. Boon (Bruxelles), F.D. Carlson (John Hopkins), B. Chu (Stony Brook), H.Z. Cummins (CCNY), V Degiorgio (Pavia), J.C. Earnshaw (Belfast), R.P.C. Johnston (Aberdeen), D.E. Koppel (Connecticut), D.B. Sellen (Leeds), M.W. Steer (Belfast), B. Ware (Syracuse), K.E. Wohlfarth-Bottermann (Bonn), H Yu (Wisconsin).

Scientific Programme

The aim of the meeting is to bring together physical scientists and biologists to explore the use of laser light scattering methods in biological research. Lectures, which will be comprehensible to members of the 'alternate discipline', will cover the following areas:

- Introduction: physical principles and biological problems
  Techniques: laser Doppler microscopy, fluorescence techniques, data interpretation
- In vitro studies: diffusion, electrophoresis, gels, model membranes, vesicles, muscles
- Whole cell movement: bacterial and sperm motility, amoeboid
- Intra-cellular motion: cytoplasmic streaming, vesicle migration, molecular motion in cytoplasm

Further details and registration forms are available on request. Completed application forms must be submitted by 28 February 1982 to Dr. J. C. Earnshaw, Department of Physics, The Queen's University, Belfast, N Ireland BT7 1NN. (028)K

# **STUDENTSHIPS**

## THE HANNAH RESEARCH INSTITUTE Post-graduate Research Studentship

Applications are invited for a 3-year studentship sponsored by an industrial company to carry out research into the heat induced gelation reactions of milks. The successful applicant will carry out research in the Chemistry Department of the Hannah Research Institute in Ayr and will be registered for a higher degree in the Department of Dairy Science of the University of Glasgow.

Applicants should have a first or upper second class honours degree in Chemistry or other suitable discipline.

Applications, including the names of two academic referees. should be sent by 11th January to:-

The Secretary, The Hannah Research Institute, AYR, Scotland KA65HL

### **FELLOWSHIPS**

# **EMBO**

**European Molecular Biology Organisation** 

# LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1982 AWARDS

Next deadline: February 19, 1982

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but subject to review of progress they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The followship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 19, 1982. Successful candidates will be notified of the their awards immediately after the meeting of the selection committee which is on April 30, 1982.

Application forms and further details may be obtained from Dr J Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1,F.R. Germany.
(W510)E

# POST-DOCTORAL FELLOWSHIP

(Mechanisms of bacterial mutagenesis and DNA repair)

Applications are invited from persons currently working in an EEC country other than the UK, or non-UK EEC citizens currently working outside the Community. Previous experience in this or a related field is essential.

Write to Professor B A Bridges, MRC Cell Mutation Unit, University of Sussex, Falmer, Brighton, England. (024)E

#### THE UNIVERSITY OF AUCKLAND New Zealand REMOTE SENSING RESEARCH UNIT

A Postdoctoral Fellowship is available in the Remote Sensing Research Unit for a period of 12 months commencing during 1982. Applicants must have completed a PhD or its equivalent before being eligible to take up the Fellowship. Expertise in digital processing techniques and remote sensing applications is desirable. The unit's current research interests include practical resource analyses of NASA and NOAA satellite data, analysis of seasurface temperatures and mapping of land resources. A monthly allowance of NZ\$1,519 will be paid.

Further information including application forms are available from Dr G R Cochrane, Department of Geography, University of Auckland, Private Bag, Auckland, New Zealand. Applications close 30 August 1982. (051)E

# UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF CIVIL ENGINEERING

#### RIDLEY FELLOWSHIP IN AIR AND WATER POLLUTION

Applications are invited, from persons who have shown themselves able to carry out original research, for the Ridley Fellowship in Air and Water Pollution tenable in the Public Health Engineering Division of the Department of Civil Engineering. The Fellowship is financed by the British Steel Corporation to promote research in some aspect of air and water pollution which is of interest to the steel industry. The proposed topic is biochemical transformations in the biological treatment of coke oven liquors but consideration will be given to other research topics proposed by the applicant.

The normal tenure of the Fellowship will be three years, tenable from 1 April 1982 or a date to be arranged. The value of the Fellowship is £6,070 (first year), £6,475 (second year) and £6,880 (third year).

Further particulars and application forms (which must be returned by 31 January 1982) may be obtained from the Registrar (Fellowships), University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE17RU. (044)E

CANCER SOCIETY of New Zealand

#### BRUCE CAIN MEMORIAL POSTDOCTORAL FELLOWSHIP

The Auckland Division of the Cancer Society of New Zealand (Inc) is offering a Fellowship for post-doctoral research in a field of Chemistry, Cell Biology, or Tumour Biology which is relevant to the interests of the Cancer Research Laboratory, located in the University of Auckland School of Medicine.

Applicants should have, or have almost completed a PhD or equivalent qualification. The Fellowship is available for 2 years with a possible extension for a 3rd year. Salary will be NZ\$18,229 per annum and a return economy class airfare will be paid. Consideration will be given to payment of other expenses, including an airfare for a spouse.

Applications will be accepted up to 1 March 1982.

Further information and application forms are available from: The Chief Executive, Auckland Division Cancer Society of NZ (Inc), PO Box 1724, Auckland, New Zealand. (033)E

#### LINCOLN COLLEGE, Oxford

# EPA CEPHALOSPORIN JUNIOR RESEARCH FELLOWSHIP IN MEDICAL, BIOLOGICAL OR CHEMICAL SCIENCES

The College invites applications from graduates, of either sex, under 28 years of age on 1st October, 1982, for a Junior Research Fellowship in Medical, Biological or Chemical Sciences, tenable for three years from October, 1982; applications from older candidates will be entertained in special circumstances only.

Further particulars may be obtained from the Rector, Lincoln College, Oxford OX1 3DR, to whom applications should be submitted by 14th January, 1982. (013)E

The MOUNT WILSON and LAS CAMPANAS OBSERVATORIES of the CARNEGIE INSTITUTION OF WASHINGTON Announce the availability of THREE RESEARCH FELLOWSHIPS

Applications are invited for Carnegie Fellowships and Las Campanas Observatory Fellowships at the Mount Wilson and Las Campanas Observatories, Pasadena, California, beginning in September 1982. Fellows will be expected to reside in Pasadena, and to devote a major portion of their time to independent research projects. They will have access to the Observatories' research facilities on Mount Wilson, on Palomar Mountain, and on Cerro Las Campanas, Chile. A cooperative arrangement between the Carnegie Institution and the California Institute of Technology permits access to the facilities of Caltech's Palomar Observatory.

Carnegie Fellowships are postdoctoral appointments, normally of two years' duration. Las Campanas Fellowships are senior research fellowships open to applicants with at least two years' experience beyond the PhD. These senior Fellowships are usually of three years' duration.

Applicants should arrange for separate transmittal of confidential letters of recommendation from three professional scientists. Applications should include biographical data, educational record with dates and degrees received, professional positions held, and a list of papers published or submitted. Applicants should also write a brief essay describing their recent astronomical research and indicating what they would hope to accomplish during the tenure of a fellowship.

Applications, letters of reference, and all supporting materials must be received before January 15, 1982. They should be sent to:

Dr. Alan Dressler, Chairman, Fellowship Committee, Mount Wilson and Las Campanas Observatories, 813 Santa Barbara Street, Pasadena, CA 91101-1292, U.S.A.

The Carnegie Institution of Washington is an Equal Opportunity Employer, M/F/H. (NW142)E

# POSTDOCTORAL FELLOWSHIPS IN IMMUNOLOGY

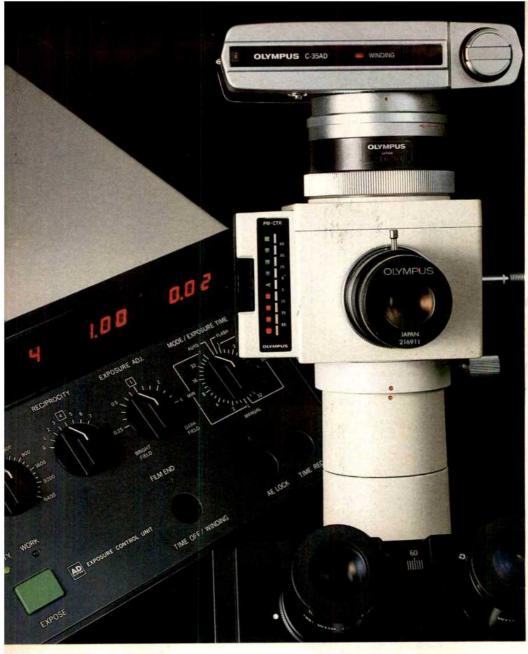

Position available for postdoctoral training in basic immunology (idiotypic regulatory mechanisms) and applied problems (tumor immunology and leukemia viris-lymphocyte interactions). Other related activities in the department include research on biology of interleukins, interferons, and cellular immunity (cytotoxic and NK cells)

Send complete CV and references to: Jan Cerny, MD, PhD, Department of Microbiology, University of Texas Medical Branch, Galveston, Texas, 77550.

An Equal Opportunity/Affirmative Action Employer. (NW137)E

For photomicrography or cinemicro graphy, it pays to match Olympus microscopes with something equally outstanding: The Model PM-10AD. The PM-10AD faithfully records the high image resolution, definition and clarity of Olympus microscopes. An it does so with the convenience of fully automatic exposure.

The time and effort you save are remarkable. Thanks to a built-in micro computer and a Silicon Blue Cell (SBC that relays information to it quickly an accurately, you need no longer worn about complicated adjustments.

The automatic exposure range is ex tremely wide, from 1/5000 of a seconto 2 hours. The microcomputer auto matically corrects the reciprocity failure characteristics of the film you are using and operates continuously to yield perfect exposures.

The PM-10AD allows automatic and manual operation. In either mode, it can be used not only for conventiona purposes but also for multiple exposures of double-stained fluorescence specimens and panorama photography, in which case uniform density is assured.

#### Other features:

- Clear digital displays include estimated and actual exposure times, time remainin to complete exposure and recall of the previous exposure time.
- Unique vibration-free electromagnetic shutter. The contact-free design provides a shutter life of at least 100,000 operation with absolutely no adverse effects on image quality.
- Optional PM-CTR color temperature meter module for simple checking and adjustment of color temperature.

# A TRIUMPH OF INSPIRED SIMPLICITY PM-10AD Photomicrography and Cinemicrography System

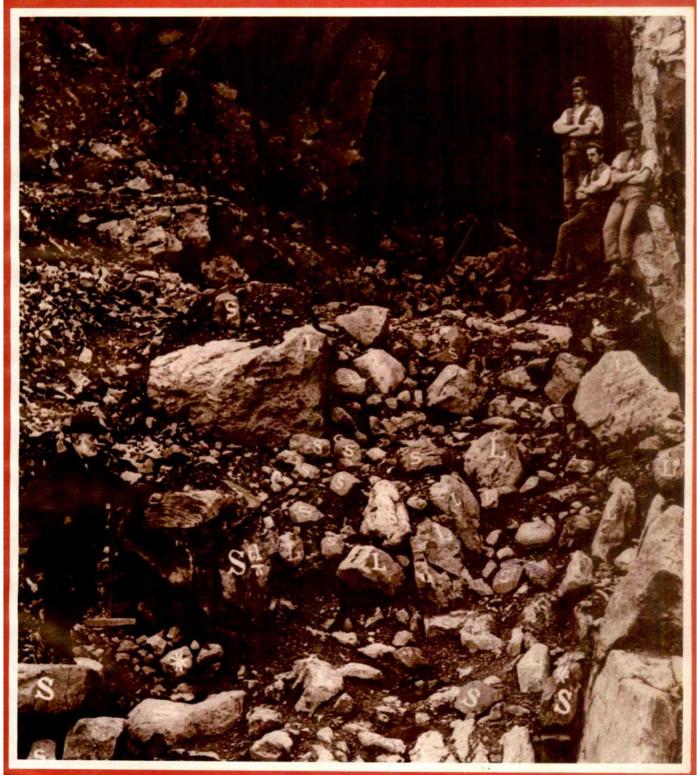

The PM-10AD is a triumph of inspired simplicity—a simplicity that means optimum results.

# THE FAST ONE!

IgGsorb is the IgG adsorbing agent that won't keep you waiting. It removes antibody and antibodycomplexed antigen from solution in a mere 15 minutes!

Highly specific for binding the FC portion of IgG antibodies, IgGsorb is a lyophilized preparation of Protein A fixed to the cell walls of inactivated **Staphylococcus aureus**.

IgGsorb has more than speed too. It has long storage life. Its homogeneity can be assured. And it serves a variety of applications, in some cases replacing charcoal, double antibody, and other cumbersome methods of separation.

Plus, there's news. IgGsorb now comes in liquid form as well as dry!

special Offer! Try it yourself and see how fast IgGsorb really is. Order a 10ml vial for just \$19.00. Or a 100ml one for \$80.00. Because two hour waits you really don't need!

# Becton Dickinson FACS Systems ADVANCES IN INSTRUMENTATION

The FACS™
Analyzer is now available as the world's newest and most innovative flow cytometer. The system measures individual cells simultaneously for

FLUORESCENCE intensity and color (using mercury-arc illumination) and for SIZE (as measured by electronic volume) at up to 1,000 cells per second. Data analysis and display rapidly provide a distribution of measured properties for evaluation of cellular subpopulations.

#### Instrumentation Firsts

The FACS Analyzer System is a highly capable laboratory instrument of the highest quality. It represents two very important firsts in instruments generally available for flow cytometry: sufficient fluorescence sensitivity is obtained using a mercury-arc light source to enable very low level immunofluorescence measurements, and these two fluorescence measurements are obtained simultaneously with cell volume. These features are provided at surprisingly modest cost for an instrument of such capabilities. Continuing operating costs are low due to the simplicity of design and use of mercury-arc illumination. Ease of operation is another direct result of the design.

## **Highest Sensitivity and Resolution**

FACS Analyzer measurements have been documented for sensitivity to as few as 30,000 fluorescein molecules. This is of paramount importance in measurement of lower-level immunofluorescence

signals, and represents the greatest sensitivity thus far achieved using a non-laser illumination source in a commercial flow cytometer. The Analyzer volume measurement is sensitive to particles as small as 1.6 microns diameter. Resolution attainable meets or exceeds that stated for test samples; that is, 2.0 to 2.5 percent coefficient of variation in fluorescence and the same in volume. Resolution of this degree is of importance in cell kinetics data representing DNA content per cell. Analysis is available with several size flow orifices to enable operation with a wide variety of samples.

### **Advanced Applications**

Since the introduction of the first FACS Cell Sorter, the number of instruments in use and their contributions to active research have steadily accelerated. Hundreds of publications have appeared in the scientific literature. There are several annual, international meetings

devoted to this technology. FACS analysis is now a major research technique in cancer immunology, hematology, cell kinetics, pathology, biochemistry, general immunology, and quantitative cytology. Cells and substances of interest include DNA and RNA, lymphocytes, leukocytes, platelets, antigens, immunoglobulins, enzymes, viruses, chemical agents, and

chromosomes. Potential research applications range over virtually all biology and medicine.

#### **Advanced Features**

FACS Cell Sorter features are of proven importance in diverse applications worldwide. Many are incorporated in the FACS Analyzer. Major features include the two fluorescence measurements made simultaneously with electronic cell volume on individual cells. Mercury-arc lamp illumination is standard, with filter sets for use with numerous fluorescent probes. Fluorescence and volume sensitivity are provided for immunofluorescence studies, and fluorescence and volume resolution

for cell kinetics work. Both logarithmic and linear signal amplifiers, front panel compensation for two-fluorescence emission overlap, third parameter gating, and ratios of any two parameters for analysis enable easy operation of sophisticated functions. Separate Sensor

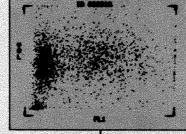

and Analysis Units enable operation of the Sensor Unit with existing FACS Cell Sorters

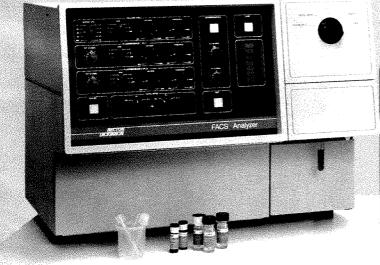

For additional information, please call or write Becton Dickinson FACS Systems.

490-B Lakeside Drive Sunnyvale, California 94086 (408) 738-8558; TWX 910 338 2026

Antwerpse Steenweg 277 2800 Mechelen, Belgium 015/29.01.43; Telex 846 72096

From detection of monoclonal antibodies, through specificity determination and purification from ascites, BRL has the reagents to enhance all phases of your hybridoma-based research.

A complete system for the screening of hybridomas that secrete mouse immunoglobulins. The kit includes: β-galactosidase conjugated sheep anti-mouse IgG F(ab'), p-nitrophenyl-β-D-galactoside as substrate, and complete protocol for use. In this enzyme-linked immunosorbant assay (ELISA), the second-antibody reagent has several advantages over alkaline phosphatase- and peroxidase-coupled antibodies: β-galactosidase is highly purified, and has a high specific activity. It is not present in most eukaryotic cells, and low background values are encountered when screening for cell surface antigens. Thus, sensitivity is enhanced. Also, p-nitrophenyl-β-D-galactoside does not show the potential carcinogenicity of other substrates used in ELISAs.

**BRL 9502 SA** 

## Immunoprecipitin

Immunoprecipitin is formalin-fixed Staph A cells for the selective adsorption of IgG immunoglobulins. It specifically and tightly binds to the Fc portion of an IgG molecule and therefore will precipitate antigen-antibody complexes.

BRL® Immunoprecipitin is subjected to rigorous quality control assays to assure you a reliable high quality product. Its features include: High specificity and affinity for IgG immunoglobulins; 1 mg of Immunoprecipitin will bind ≥ 8 µg purified rabbit IgG ■ High stability for at least four months when stored at 4°C ■ Complete elution of the antigen from the absorbant for both analytical and preparative purposes Completé protocol describing the removal of loosely bound proteins to reduce contamination of antigen by bacterial proteins

**BRL 9321 SA** 

# Protein A Agarose

BRL® Protein A Agarose is an affinity matrix prepared by covalently coupling purified Protein A to agarose beads. Protein A binds to the Fc portion of IgG molecules without interfering with ability of the immunoglobulin to bind antigen. This specificity permits the single-step purification of IgG antibodies and some IgM and IgD classes. BRL® Protein A Agarose is distinguished by: Stability over a wide pH range (2 to 11) Compatability with strong denaturants like guanidine hydrochloride and urea Actual lot analysis to determine the amount of Protein A bound to the gel (1.8 to 2.5 mg/ml of gel), and the binding capacity for human IgG (8 to 10 mg/ml of gel)

**BRL 5918 SA**

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

OLYMPUS started the true pocket recorder revolution when they developed this light weight, high precision and exciting new MICROCASSETTE PEARLCORDER system for business and pleasure.

We offer readers part of this revolution with the latest and advanced 2 speed OLYMPUS PEARLCORDER S802. The capstan drive 8 oz MICROCASSETTE will give you up to two hours recording and play-back. (Unlike Mini-recording machines). The S802 is a light weight complete miniature recording system, capable of accepting verbal notes, record business meetings, computer programmes and even your favourite music. The S802 has a comprehensive range of attachments, including sub-miniature microphones, remote control, conference room amplifier, telephone pick-up, TRANSCRIBER for your secretary etc.; all this together with a 1 year guarantee from OLYMPUS, makes the S802 an absolute must for all busy Businessmen and Women both at home and at work. In addition we offer a 14 day complete money-back guarantee, at a price which we believe like the S802 is unbeatable. Batteries not included.

The reason more researchers buy our CAMP and cGMP kits in the first place is convenience: They're great time and trouble savers. But the reason researchers keep reordering is peace of mind: Our kits assure lot-to-lot sensitivity and reproducibility that does wonders for their confidence in the end results.

Everything you'll need is in the kit — pretested, matched, ready for use at room temperature. No salting out required, no second incubation . . . because the antibodies are preconjugated. Sensitivity is in the femtomole range.

And if you prefer to count by liquid scintillation, you can, using a technique developed by our LSC Applications Laboratory that is equivalent to gamma counting. Ask for it when you call in your order.

Meanwhile we'll be glad to send you details of our convenient, dependable Cyclic AMP and GMP [125]] RIA Kits.

Simply circle the inquiry number.

# Computerized Cell Sorting and Analysis from Ortho Ortho offers unexcelled systems for immunobiology researchers

LYMPHOCYTES

MONOCYTES

Three major subpopulations of white cells by forward and 90° light scatter measurements of whole blood (RBC lysis only). Using Ortho-mune Monocional Antibodies, gating on the lymphocyte population, human peripheral T lymphocytes (OKT3 \* cells) can be quantitated and/or sorted.

**GRANULOCYTES** 

it can perform rapid multiparameter sort decisions while simultaneously providing complete statistical data analysis. This capability provides significantly higher throughput and increased sorting efficiency.

Wide Applicability

FORMARD SCATTER The system has proved extremely valuable in cell-antigen and tumor studies. It can also be

employed for research into cell sizing, DNA and chromosome analysis and many aspects of cell kinetics and microbiology. The exceptional versatility of the system allows it to keep pace with the researcher's interests, never to limit them.

**OKT3 POSITIVE** 

Green Fluorescence Total Professional Support

Ortho's interest in cellular biology extends beyond producing instrumentation. For example, Ortho has developed Ortho-mune\* monoclonal antibodies, the first panel (for research use only) of murine monoclonal antibodies reactive with human T lymphocytes. The company maintains wellequipped applications and training laboratories to develop new techniques and to provide consultative services for customers.

The results of these investigations and others are published in Protocols so that other researchers may share the results. Free copies are available by contacting Ortho.

Ask about the Cytofluorograf Flow Cytometer, 2150 and the complete range of Ortho services. Contact Ortho Diagnostic Systems Inc., Research Instruments Division, 410 University Avenue, Westwood, MA 02090 (617) 329-6100.

90" SCATTER

Ortho Diagnostic Systems has established a firm leadership position in cell sorting and analysis instrumentation-in fact, acceptance of Ortho systems by the scientific community has been so great that these instruments now are considered the standard of performance in the field.

#### Versatile Instrumentation

The Ortho Cytofluorograf\* Flow Cytometer is an example of that leadership and commitment to research. As the only flow cytometer to offer a choice of five lasers, (including two installed as standard), the Cytofluorograf provides exceptional applications flexibility.

Flexibility is enhanced further by a modular design which allows the system to be upgraded as research needs change. Performance too is outstanding with analysis rates of up to 10,000 cells per second. And only Cytofluorograf offers direct measurement of seven optical parameters including axial light loss, a valuable technique that allows the use of non-fluorescent stains.

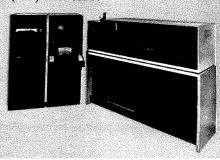

The new 2150 Computer and software can acquire up to 16 histograms and simultaneously display any four of these, all in real-time, allowing the operator complete control over all aspects of the experiment. Because 2150 has two independent microprocessors,

# INTERNATIONAL DRTALITY STATISTICS

Michael Alderson, Professor of Epidemiology at the Institute of Cancer Research

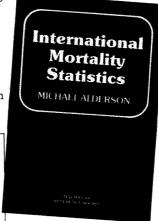

For the first time ever, 20th century mortality statistics are now available in a single volume, working with a common statistical base and a common set of premises.

405 pages of clearly laid-out tables present mortality statistics for 32 countries, 25 of them European. They are tabulated by sex, five-year periods from 1901 to 1975, 178 causes of death, and country.

Six introductory chapters give full explanations of the statistical method used, the validity of the data, and alignment of the international classification of diseases. This enables you to make your own evaluations and comparisons using the data, rather than providing a textual interpretation of the tables

If you want to examine long-term mortality trends in one country, or to compare patterns in different countries, this book is your essential reference.

The European countries examined are: Austria, Belgium, Bulgaria, Czechoslovakia, Denmark, England and Wales, Finland, France, Greece, Hungary, Iceland, Ireland, Italy, Luxembourg, Netherlands, Northern Ireland, Norway, Poland, Portugal, Romania, Scotland, Spain, Sweden, Switzerland and Yugoslavia. Outside Europe data are presented for the USA. Canada, Japan, Australia. New Zealand, Chile

## 17 December 1981

# One message on the state of science

The new Presidential Science Advisor last week gave the House of Representatives a vision of how smaller budgets may bring strength. He was partly disingenuous; may he also be right?

The United States Congress has a built-in flair for the theatrical. So much is clear from the circumstances that brought Dr George Keyworth and Dr Frank Press (his predecessor as Presidential Science Advisor now transmogrified to president of the National Academy of Sciences) to the same witness table last week (see page 601). True to expectation and perhaps even to form, Dr Keyworth, the government representative, talked confidently of how his government's policies would make the United States research enterprise more and not less efficient. Dr Press, a little on the defensive, offered a compact between the research community and the United States Administration that would assure basic research in the United States of modestly rising budgets and the United States government of the cooperation of the research community in transferring funds from the "less productive areas or institutes". Both witnesses were talking about the future, naturally enough. Neither of the set speeches mentioned the 12 per cent cut in federal budgets which President Reagan declared in August but which Congress will probably, in the end, decline to give him. But Dr Keyworth's vision was of a future so distant that, by the time it arrives, he may again be an ordinary person not bound to support the policies of the administration of the day.

Whatever the time scale of their dreams, however, Keyworth and Press agreed last week on one essential point — that the federal government has a continuing responsibility for the support of basic research. Keyworth argued that the private sector cannot be expected to support a sufficient effort in basic research, given its short-term need for profit; Press tended to quote President Lyndon Johnson on the subject. One obvious difficulty, which each of them might have mentioned, is that Congress is unlikely to endorse such a fine distinction between basic research — the pursuit of generally unpopular academics and what is called applied research and demonstration. Why should a congressman, never more than two years from his reelection ordeal, vote for the general distribution of research funds to the generality of academics when he could vote instead for his own state's favourite federal laboratory or demonstration project? Dr Keyworth should have been prepared to remind Congress of its own responsibilities. Dr Press would no doubt have been prepared to back him up with accounts, gathered at first hand, of how the pork barrel rolls.

For the immediate future, the outstanding question is whether the scientific community is in a position to do what Dr Keyworth asks of it, and to use the system of peer-review committees, and of the advisory committees that advise the grant-making and mission-oriented agencies respectively, in such a way as to concentrate funds for basic research in fields of enquiry and on institutions that are likely to make best use of them. Broadly speaking, the answer is that it all depends. For Press is also right to imply in what he said last week that the research community can do this kind of job when it believes that it can do so safely, knowing that its paymasters will not take its recommendations of places or people from which funds can be withheld as licences to go ahead while saying that recommendations of where support should be increased can wait until the economy has improved. Dr Keyworth's speech last week, full though it was of references to a creative basic research community x years from now, conspicuously lacked a sense of responsibility towards — or even regret for - those who have contributed to the same endeavour in

the past x years. Keyworth was looking not at the future but at the horizon beyond it.

Press's recipe for the immediate future is, unfortunately, equally unpalatable. Faced with present economic uncertainties, the United States government could not agree to a compact that would assure basic research of some specified rate of growth each year. The economic crisis that afflicts science in the United States (and elsewhere) has arisen precisely because people are uncertain about the economic future. Other institutions are similarly afflicted. None can be insulated. Keyworth last week would have been wrong to promise that they might be. The best course for him and Dr Press for the weeks ahead will be to make plain that nobody is owed a living, but that the government will do what it can, within the resources at its disposal, to make the best use of what can be spent on basic research.

Two minor scandals stand out from last week's exchange. Dr Keyworth argued in his statement that things may not be too bad because the Pentagon's spending on basic research will be increasing in the years ahead. One trouble is that what the Department of Defense counts as basic research is not always what other people understand by the term. Another is that the Pentagon's sense of what is excellent is often compromised by its sense of what may be expedient. If the traditional and trusted sources of support for basic research are to be cut back but the Pentagon enlarged and the research community as a result given less of a say in what is excellent and worthwhile, should not Dr Keyworth have been urging that this year's increase in the Pentagon's operating budget should be matched by a corresponding increase of the budgets of the agencies dedicated to (and skilled at) providing support for basic research?

The second scandal that will stick in people's minds is Dr Keyworth's homily last week about the neglect of science and mathematics in American high schools. Since the post-sputnik era in the late 1950s, enthusiasm for the physical sciences has evidently waned. Rightly, Dr Keyworth shares with other observers a sense of anxiety about the consequences. Will United States universities in future be providing remedial mathematics as freely as they now have to offer remedial English? Or will it simply be that the brightest young people follow different kinds of courses, letting American industry depend on skilled people recruited from abroad? The fears may be exaggerated, but Dr Keyworth's defence of his government's inaction is equally an exaggeration of the doctrine that Republican governments are ideologically opposed to intervention in other people's affairs. Keyworth said that the Administration is concerned at the decline in high school studies in the physical sciences, but that education is a matter for state and local government and that he had confidence that, sooner or later, they would see the light. Can he be sure, especially when the government for which he works has decided (as it did in its March budget) that the National Science Foundation should be effectively robbed of funds for the further development of the science curriculum? If the benefits of basic research are too distant to be left to industry, can it safely be assumed that the long-term needs of the educational system can be entrusted to embattled school committees? And if not, does not the Administration have a duty to show the way? The National Science Foundation's educational programme may have aged ungracefully, but the Administration cannot wash its hands of the set of problems its science adviser has identified.

# Finniston's pale shadow

The British Engineering Council now exists. Its first task is to define for itself a role.

Engineering education promises to be in the 1980s a lightningrod for public solicitude to take the place occupied in the 1950s by the cause of motherhood. In the United States last week, Dr George Keyworth was wringing his hands before Congress in anxiety about the difficulties of recruiting and then keeping members of university engineering faculties — but was confident that the market would somehow find a way. In Britain, engineering education has been a public issue for at least four years, since Sir Monty Finniston's committee was set up. Broadly speaking, there have been three distinct complaints. First, there is not enough engineering education. Second, what there is is either inappropriate or not good enough or both. And third, in universities as in the world outside, engineering has a lower status than science. Finniston's report (now nearly two years old) embraced all these views and more, and urged that there should be an Engineering Council equipped with powers over engineering curricula in all kinds of teaching institutions and with the funds with which to implement reforms. Implicitly, Finniston asked that his council should supersede the existing engineering institutions, some of them monuments to the Industrial Revolution.

The contrast between the United States and Britain is instructive. In both countries, it is acknowledged that engineering skill is one of the mainsprings of industrial innovation, productivity and prosperity. There, however, the similarity ends. Dr Keyworth last week was merely echoing the longstanding complaint that American industry is so fully seized of the economic importance of engineering skill that universities cannot easily compete for teachers — and graduates flock off to lucrative jobs in industry undiverted by the prestige of the academic life. In Britain, much the same may be happening in fields of engineering linked with computer engineering, but for the most part those carrying a torch for British engineering are still mouthing hackneyed slogans — that engineering (and engineers) should be accorded more "status" by everybody in sight.

This is the spirit in which the Committee of Engineering Professors has in the past few months been urging that the Science and Engineering Research Council should be split into two, one part concerned with the support of engineering research in universities. For, the argument seems to be, how can engineers respect themselves without a research council to call their own? (The proposal, mercifully, seems to have been headed off by the willingness of what used to be the Science Research Council to mention engineering in its title.) Similarly, there is excited talk, from people such as Lord Caldecote, the president of the Engineering Fellowship (another pressure group), that the new council may help to give the engineering professions public esteem. What these complainants consistently overlook is that the exercises in public relations on which they are embarked are merely palliatives, and that British engineering would be better off if its esteem were reflected in the eagerness of British industry to snap up young engineers — and to pay them decent salaries.

How is that to be accomplished? And will the new council help? Much will depend on its willingness to come to grips with the educational questions which Finniston grasped too firmly — like a man picking up a stinging nettle. In spite of the inquiries of the past four years, nobody is much wiser about the balance that should be struck between the various ingredients in various kinds of engineering courses. Instead, at the university level, the assumption is being established that there should be two kinds of courses, one lasting three years and one for four.

Unfortunately, very little thought has been given to the academic content of these courses, and the suspicion remains that university engineering courses, like those in other educational institutions, are too narrow because the separate engineering institutions too jealously insist that courses should concentrate on the topics judged to be relevant to their fields of interest.

Mechanical engineers worry about the design of gear wheels, civil engineers about the design of bridges, electrical engineers about the design of circuits and so on. The influence of the engineering institutions stems from their willingness to grant exemption from some of the requirements for professional qualification to students who have followed approved courses. This right will remain under the new arrangements. But who is to say that these are the lines on which engineers should be taught? Might not a preparation in something called engineering science be a better preparation for work in a profession that must turn its hand to almost everything? And how is the engineering profession to come to terms with the disconcerting truth that many whose academic training is quite different from that now required of engineers still function in industry as engineers? It would be splendid if the new council chose, as its constitution allows, to license the occasional physicist or chemist to practise as an engineer. Better still, it should take a fresh look at what academic preparation is needed by those who may in future keep British industry alive. But it should firmly acknowledge that a demand for more prestige for engineers is tantamount to a demand that water should run uphill.

# Who pays what piper?

British universities and football clubs are in trouble. Can they make common cause?

Economic crisis is at least even-handed. Last week, British newspapers were full of gloomy prophecies of how no fewer than a dozen among three-score British institutions are threatened with bankruptcy in the months ahead. The causes are easily described. Running costs have risen. The cost of employing staffs has become doubly onerous - the annual salary bill is high, but the longer-term implications of people's contracts with their institutions are a shadow over the future. But income is falling. Traditional customers can no longer afford to take advantage of the services the institutions exist to provide. Inevitably, where the threatened institutions command particular loyalty from the cities in which they are based, especially when they are the only one of their kind, bands of loyal supporters have formed to conjure a phoenix from the impending ashes. Elsewhere, newspaper columnists comfortably bemoan the passing of a revered tradition and a past source of public pleasure and enlightenment. The institutions are the professional (commercial) football clubs that play with a round ball, otherwise known as soccer or "association football' clubs.

British academics reading this torrent of gush (which may be made meaningless if only the clubs can negotiate a better television contract next season) may be forgiven for not recognizing that much of the purple prose could apply to the institutions for which they work. The proportions at risk are about the same. The inexorable increase of expenditure has similar causes. And income is falling because the government, effectively the only customer, cannot afford to pay for the services on offer. But may not academics, most of whose institutions will be making critical decisions about their future this week and next, learn from what the football clubs are planning?

Many football clubs plan to make better use of their fixed plant; universities might similarly offer courses out of business hours or in vacations. Other clubs plan to increase their ancillary income; selling franchises to put university coats of arms on tee-shirts would hardly be lucrative, but what of the benefits from academic enterprises with which British univesities have so far only flirted? Some clubs plan to sell off players, presumably the most saleable and thus probably the best; but universities are thinking of offering early retirement only to the least employable. No football club lacks a local constituency, a group of people to which is has given pleasure in the past and which is now prepared to fight that it should have a future; too many universities, unfortunately, are unable to make a comparable claim on their localities. In a macabre way, it will be interesting to see which threatened group does best in the months ahead.

# Keyworth and Press on basic science

# Researchers to decide where funds go?

Washington

In the first coherent statement of the Reagan Administration's thinking on science policy, Dr George (Jay) Keyworth, the president's science adviser, said last week that the scientific community must be prepared not only to help identify areas in need of increased support, but also to say where support should be decreased.

The time of constantly growing budgets across the board had passed, Dr Keyworth said, and the scientific community's "best and most thoughtful judgement" was needed to identify areas to deemphasize as well as those meriting new emphasis. "To those who object to such undertakings, and to all of my scientific colleagues, I must say that if scientists do not make such choices, others will, but with less acuity."

Dr Keyworth was addressing a hearing of the House of Representatives Science and Technology Committee on the implications for science of the present budget reductions. At several points in his testimony, Dr Keyworth claimed that the Reagan Administration was promoting a fundamentally new approach to the government's responsibilities for science and technology. "I am proposing a federal role in research and development which is appropriate to the 1980s — appropriate to a national mood which calls for increased vigour and acceptance of responsibility by individuals and organizations in the private sector and decreased involvement by the federal government in many of our affairs", Dr Keyworth said.

Yet apart from promoting the need to trim research budgets to fit straitened economic circumstances, much of the substance of what Dr Keyworth had to say was similar to statements to the committee made by his two predecessors, Dr Frank Press, science adviser to President Carter and Dr Guyford Stever, adviser to President Ford. All three stressed the federal government's responsibility to promote basic research as a long-term investment in the future. And all agreed that short-term research and development should primarily be the responsibility of the private sector.

Dr Keyworth, in line with the overall policy of the Reagan Administration, emphasized that science policy had to be carried out in the context of other national policies such as national security, international relations, energy, social services and the economy. "For example, science policy, made without considering econo-

mic policy, is irrelevant", he said.

Dr Keyworth's immediate predecessor, Dr Frank Press, now president of the National Academy of Sciences, while accepting the need for financial restraint, gave last week's committee hearing a sharply different view. He advocated a ten-year "compact" between government, industry and universities to establish new national goals for the support of science. This would include commitment to an annual real growth of between 1 and 2 per cent in the scientific research budget; an additional 1 per cent growth to support special "targets of opportunity" in different fields; and a real growth of 1 per cent, equivalent to about \$50 million a year in the contribution made by industry to university research.

To a large extent, however, the differences in the statements from Dr Keyworth and Dr Press were a reflection more of their different constituencies than of disagreements on substance. Both agreed that there should be a reduction in federal support for "demonstration projects" that should properly be taken over by the private sector. And Dr Press spoke of Dr Keyworth's "courage" in

making uncomfortable decisions about what research projects should be cut.

Responding to a question about press reports that he had recommended the elimination of all new planetary exploration missions by the National Aeronautics and Space Administration (NASA) over the next decade—a proposal being discussed this week by President Reagan and NASA administrator James Beggs—Dr Keyworth emphasized the many scientific gains to be made from space shuttle missions, and suggested that this was one area in which direct scientific comparisons might be made.

Expanding on a theme of several of his earlier speeches, Dr Keyworth told the committee that there were several reasons why the United States could not expect to be preeminent in all scientific fields. He also warned against the tendency to avoid tough decisions about which projects should be cut by applying cuts uniformly across all fields. "I believe the discipline of making such hard choices will ultimately benefit science, just as the occasional pruning of a tree can promote, rather than retard, its heal."

David Dickson

### Spain has the money but not the people

Science in Spain seems to be embarked on a period of rather heady growth. Money under the direct control of the Spanish science research council, the Consejo Superior de Investigaciones Cientificas (CSIC), will triple next year if decisions taken by the lower house of the Spanish parliament are confirmed by Senate. This comes on top of a doubling last year of the centrally administered "funds for research", from which CSIC draws the largest single portion. One sign of how the wind is blowing is the story of a Spanish chemist, recently returned from the United States, in a poorly-equipped CSIC laboratory. In the past few weeks he has found himself spending money "eight or nine hours a day" bringing his laboratory up to scratch; and he has not even had to submit a formal grant application.

CSIC plays a major role in science in Spain, maintaining 23 institutes in the humanities and 77 in natural sciences and employing 1,600 scientists plus 4,400 supporting staff. But the Consejo is not the only beneficiary of increased spending. Parliament has also agreed to create two new research funds, on which universities (and others) will be able to draw: one to be controlled by the Ministry of Industry, and one by the Ministry of Health, together increasing the government research budget by about a quarter.

The regional distribution of support is also becoming a shade more equitable. Whereas some 85 per cent of the central funds for research have usually been spent in Madrid, parliament this year has insisted that 25 per cent be spent in the regions; and the autonomous government of Catalonia is also expected to increase its fledgling research budget next year, from 100 million pesetas (around £500,000) to 200-250 million pesetas.

In total, over the past two years Spanish spending on research and development has nearly doubled as a fraction of gross national product from around 0.3 per cent to 0.5 per cent now — still way below the developed world average of something over 2 per cent but an increase which is already proving difficult to manage.

The problem is people. The truly effective Spanish research community is very small, and there is a government freeze on new appointments. This is having two serious effects, which some feel must be corrected quickly or the new money will be merely wasted.

First, there are not enough highly qualified scientists to act as critical referees in all fields in which Spain would wish to do research; although arrangements have been made for refereeing all proposals, in practice the judging has proved to be imperfect and partisan. An international refereeing system is proposed by those who would survive it; the others — inevitably the majority — resist.

Second, there are too few posts becoming vacant to employ the rising tide of experienced Spanish scientists who wish to return from other countries and make use of the new money. So paradoxically the coffers are open, but there are good

scientists unemployed.

The man who may change all this is the new minister for universities and research, Professor Federico Major, recently returned from Paris after a spell as Deputy Director-General of UNESCO. Major, a 47-year-old developmental neurobiologist, has kept in touch with science despite a long career in politics. He is a personal friend of King Juan Carlos, and yet is right wing (he was minister of universities under Franco) and so may be able to ride the strong conservative opposition in Spain. He has to steer through a new law for the universities (now entering its seventh draft). And he appears to have been impressed, during his time in Paris, by the new French commitment to science as a means of economic development. He is already talking of a "law for science" which would define a budget and a programme for a stretch of a few years, so clearing all political hurdles in one jump. This is exactly the strategy of the French minister for science. It will be interesting to watch how far Professor Major will mimic him.

Robert Walgate

#### UK biotechnology

### **Blood money**

A British publicly-funded organization for encouraging innovation in industry has made its second major investment in the fledgling biotechnology industry. The British Technology Group (BTG — an amalgamation of the former National Research Development Corporation and the National Enterprise Board) announced this week that it is investing £2 million in Speywood Laboratories Limited of Nottingham for the development of new techniques for blood protein manufacture. Prutec Limited, a subsidiary of the Prudential Assurance Company, will be matching BTG's investment.

BTG's other biotechnology venture is Celltech, the company it established last year with three finance houses and the Medical Research Council to develop recombinant DNA techniques for manufacturing medical products, including monoclonal antibodies. The group's latest venture is to develop a new fractionation technique for manufacturing blood proteins, an area in which Celltech is not involved.

Speywood, a small company set up seven years ago, will use the £4 million roughly to double the size of its factory and research laboratories. Its initial aim is to improve its polyelectrolyte process for fractionating blood cryoprecipitates, which allows the separation of a greater variety of blood proteins than the traditional Cohn process for fractionating whole-blood plasma. The company has already used the new technique for isolating a pure form of factor VIII from pigs' blood for use in particularly sensitive human patients. Clinical trials are expected next year. It now plans to expand factor VIII

production and extend the technique to factor IX, factor VWF (for treatment of von Willebrand's disease) and fibronectin.

Speywood is the only commercial company now producing blood products in Britain, the bulk of production being controlled by the health department through its Blood Products Laboratory at Elstree, and Speywood's plans for expansion are likely to be welcomed by the National Health Service, which has to import a large proportion of its supplies.

Speywood's longer-term goal, however, is to develop and use recombinant DNA techniques for manufacturing blood proteins such as factors VIII and IX, fibronectin,  $\alpha_1$  antitrypsin and albumin.

David Heath, managing director of Speywood, welcomes investment from BTG and Prutec not only for the money but also because it gives the company access to expertise on recombinant DNA technologies in universities (BTG acts as a "broker" between industry and the universities). He hopes that the £4 million will launch the company into an expansion plan costing about £19 million over the next five years. Later on, he will be looking for further investment, but BTG is for the time being non-committal, preferring to see how the company shapes up before committing itself further. Judy Redfearn

#### **Telecommunications**

# French hanging on

Brussels

French doubts about the wisdom of opening up some public purchasing contracts in telecommunications to its partners in the European Economic Community held up agreement last Monday on a set of recommendations designed to stimulate the growth of the European market in telecommunications.

Although the recommendations would not be binding, they constitute a first step towards achieving community-wide services and a community-wide market for terminal and other kinds of equipment. The telecommunications administrations of the various member countries have, of course, been cooperating for a long time but the supply of equipment for national networks has tended to remain in national hands. Following the meeting of the Council of Telecommunications Ministers in December 1977, the European Commission established a working group on future networks which has recommended urgent action in the field of digital networks. But the different policies being pursued and conflicting commercial considerations continue to hamper progress.

The first recommendation is for consultation with a view to ensuring that new services are introduced within the community only when they are mutually compatible. Second, the telecommunications administrations of member

#### Pleasant surprise

The shortfall in admissions of overseas students to British universities has not been as great as anticipated. According to the University Grants Committee (UGC) admissions of overseas undergraduates in 1981-82 totalled 4,918 compared with 5,017 in 1980-81, a shortfall of about 2 per cent. Postgraduate admissions were 7,414, only 0.5 per cent less than in 1980-81.

These figures, however, come on top of reductions in 1980-81 compared with 1979-80. The sharpest reductions then were in students from the United States and Malaysia which sent 1,105 and 3.988 undergraduates respectively, compared with 1,450 and 4,188 in 1979-80. Most other countries cut back by two to five per cent. The exceptions were West Germany, Hong Kong and Nigeria which sent more students than in 1979-80. The largest contributors of overseas students are still Malaysia, Hong Kong and the United States, between them sending more than half of Britain's total overseas enrolments.

As yet UGC has no figures for individual universities or for the countries of origin of new entrants for 1981-82, but the unexpectedly small decline should mean that some universities, at least, have not suffered as severe a loss of in income from overseas students' fees as had been feared. The effect may be to lessen the impact of the government's cut in the university grant.

Judy Redfearn

countries should not discriminate between domestic and other EEC suppliers of telematic terminal equipment by means of type approval procedures taking longer than six months, or which are more complex and costly to comply with than those employed elsewhere. But it was the third recommendation which caused the greatest problems. This specified that for the period 1981–83, telecommunications agencies should seek tenders from suppliers who manufacture in other community countries for at least 10 per cent of their annual orders.

The French quibbled about the phrasing "suppliers who manufacture", partly because, as one diplomat put it, "they don't want to go ahead with the recommendations anyway". But the French also want to avoid loopholes that will open up their market to non-EEC countries. The worries of the Germans, the other main objectors to the recommendations, were, however, removed. The Bundespost's ambitious videotext programme is being accompanied by a new law to extend its monopoly in new information systems and terminals such as modems, although this move will be examined by the European Commission's directorate on competition.

#### Chemical health risks

### Not so great

Washington

After reviewing the scientific literature on the health risks associated with the use of nitrites and nitrates as food preservatives, a committee of the National Academy of Sciences National Research

#### Backing a winner

One of the few European research facilities which can claim a substantial lead over the United States in both size of budget and research quality, the high flux neutron beam laboratory at Grenoble (Institut Laue-Langevin, ILL), now has the money and agreements it needs to keep ahead of the opposition until the 1990s, its directors believe.

In the past two weeks two major decisions affecting the future of ILL, which provides services to 1,700 visiting scientists each year, have been taken. The treaty between France (the host country), Germany and the United Kingdom, which guarantees support for ILL, was extended a further 10 years to 1992; and the international steering committee, which decides the budget and a five-year forward look each December, has agreed to a substantial addition to the neutron source costing some £2 million, and an increase in the number of major instruments at Grenoble to make use of it.

The improvement — a new "cold source" which produces neutrons at long wavelengths for large-scale structural studies such as of polymers or of biological materials — was the principal part of a large programme approved in outline in 1979; but there were fears that cuts in German and British budgets might threaten it. These fears have now proved unjustified.

ILL directors see the new source, basically a tank of liquid deuterium which cools thermal reactor neutrons to low velocities and hence long de Broglie wavelengths, as a means of capitalizing on ILL's greatest successes (which have been in long-wavelength scattering) and of countering — or complementing competition from accelerator-driven 'spallation' neutron sources. These may provide improved flux and resolution at short wavelengths by making use of spallation reactions, where incoming protons (from an accelerator) collide with heavy neutronrich nuclei (such as uranium) to produce a spray of neutrons ten to one hundred times the intensity of the incident proton beam. Spallation sources are planned in Japan, and at Argonne and Los Alamos in the United States; and one is under construction at the Rutherford Laboratory in the United Robert Walgate Kingdom.

Council (NRC) has concluded that current exposure levels constitute an insufficient risk to require major reductions in their use.

However, because many nitrosamines and other nitroso compounds which can be formed from nitrates and nitrites have been found to cause cancer in laboratory animals, and can therefore be associated with cancer in humans, the committee has recommended some reductions.

The committee was set up by NRC at the request of the US Department of Agriculture and the Food and Drug Administration to study the health effects of nitrate, nitrite and N-nitroso compounds, following the publicity which occurred in August 1978 when workers at Massachusetts Institute of Technology found that sodium nitrite caused tumours in the lymph systems of rats.

At the time the federal government rejected calls for a temporary ban on the use of nitrites as a food preservative, but established an immediate study of the problem. In August 1980, the two agencies announced that they had found "insufficient evidence" to link the use of nitrites to cancer but said that they intended to study the issue further.

Last week's report is the first of two to be produced by NRC in response to the government's request by a panel chaired by Dr Maclyn McCarty of the Rockefeller University in New York. The panel's second report will consider current research and prospects for developing alternatives to nitrite as a food preservative.

In its first report, the committee says that the results of limited experiments suggest that nitrate is neither carcinogenic nor mutagenic, but that evidence from several epidemiological studies in human populations is consistent with the hypothesis that exposure to high levels of nitrate may be associated with an increase of cancer of the stomach and oesophagus, recommending further studies to confirm these preliminary findings.

The committee also says that scientific evidence does not indicate that nitrate acts directly as a carcinogen in animals. In contrast it says that most N-nitroso compounds are carcinogenic in laboratory animals, mutagenic in microbial and mammalian test systems, and that some are teratogenic in laboratory animals. However, it adds that such results are of limited value for predicting the quantitative risk to humans.

At the same time, it points out that nitrites found in cured meats account for only a small proportion of the total exposure to nitrosamines.

According to the committee, cigarettes represent the single largest source of nitrosamines, with a daily pack of American filter cigarettes producing an exposure of 17 microgrammes. In contrast, the level ingested from all dietary sources is about 1.1 microgrammes a day.

**David Dickson** 

#### Satellite launcher market

### Ariane set fair?

The European commercial satellite launcher business is itself well launched. With two successful test flights to its credit, Ariane, the European Space Agency's heavy satellite launcher, is already qualified for service. So whatever the outcome of the fourth and final test flight this week, the fifth launch next March will be the first of six promotional flights, after which production and marketing of subsequent launchers will be officially handed over to the French-based company Arianespace. But the space agency's role in rocket development continues. By 1983, Ariane 2 and 3, capable of placing 2,100 kg and 2,580 kg payloads into geostationary transfer orbit, will be in service.

Further ahead, in 1985 there will be a test launch of Ariane 4, which uses the basic design of Ariane 3 but is to be offered in six versions, with payloads of 2,300–4,300 kg, achieved by strapping onto Ariane 3 various combinations of liquid and solid-propellant boosters. This more ambitious version of Ariane 4 has been prompted by calculations of the mass of the telecommunications statellites likely to be built towards the end of the decade. The European Space Agency's swift approval of this version of Ariane 4 is evidence of its determination to compete internationally in the growing market for satellite launchers.

The only other present source of commercial launching facilities is the United States National Aeronautics and Space Administration. The Thor Delta and Atlas Centaur launchers can put 900 kg and 1,850 kg into geostationary transfer orbit respectively, compared with the current capacity of Ariane 1 of 1,700 kg. Although the shuttle will be capable of carrying much heavier payloads, Europeans are quick to say that it is technically unproven and that availability is still in doubt.

Meanwhile, there is little competition for Ariane from elsewhere. The Soviet Union has geostationary launch capabilities of 2,400 kg and 5,000 kg aboard Soyuz and Zonda, but these are not generally commercially available. Thus the most likely competition in the future will come from Japan, which already has a small rocket capable of launching 220 kg into a low circular orbit and is developing a heavy satellite launcher, which could rival Ariane, for a first launch in 1987.

The only other contenders so far are China, India and Brazil. China and India have already launched small scientific payloads into near-Earth orbits. The immediate goal of the Indian programme is to develop a Polar Satellite Launch Vehicle by the mid-1980s for putting meteorological and remote sensing satellites weighing up to 600 kg into near geopolar orbits which pass over all points on the Earth at the same time of day. Only then will attention be turned towards a launcher

for heavy communications satellites.

Brazilian plans are more tenuous. For a decade, the government has been talking of launchers to place remote sensing and meteorology satellites into orbit, though little seems to have been done.

Judy Redfearn

#### Polish science advice

#### Reforms in limbo

One of the casualties of the Polish government's sudden suspension of the Solidarity trade union at the weekend may well be the draft bill that would have made it obligatory for government agencies to consult "scientific experts" before making important decisions. News of the bill came in a communiqué issued last month after a meeting between the Prime Minister, General Wojciech Jaruzelski, the Primate of Poland, Archbishop Jozef Glemp and Lech Walesa, leader of Solidarity.

To be effective, the proposed bill would have had to ensure that consultations were more than an empty formality. In some cases it would seem, past governments acted without even an appearance of consulting scientists. A notorious case was the siting of vast industrial plants — the Skawina aluminium smeltery and the Lenin steel mills — just outside Krakow. The decision to develop industry in the area in the 1940s had political overtones but meteorologically Krakow is a very poor site because of the limited circulation of the air. The toxic fumes from industry have undermined the health of the population and made the produce of farms unsafe within a radius of 50-60 km.

Until September 1980, any public discussion of such issues was impossible. Within a month of the signing of the Gdansk accords, however, a new Club of Polish Ecologists was established, based in Krakow, which early in January succeeded in having the obsolete production lines at Skawina (which had been emitting hydrogen fluoride) closed down. General Jaruzelski has been a strong supporter of moves to give scientists a louder voice, and he seems committed to continuing with consultations. But exactly who will be involved in any future talks is now unclear, as a new format is likely to emerge after a brief hiatus.

A second new bill now being prepared is aimed at reforms in the Academy of Sciences. The academic secretary of the academy is at present directly responsible to the prime minister and has himself quasiministerial rank. In recent months there has been a considerable movement within the academy to change this anomalous status by making the academic secretary responsible only to his fellow academicians. It seems likely that the prevailing "state of emergency" will mean a considerable weakening of provisions in the bill aimed at increasing the independence of the academy. Vera Rich

#### Creation on trial

# **Battle engaged**

Washington

While a federal judge in Little Rock, Arkansas, listened to the closing arguments this week in a case claiming that a new state law which requires the teaching of "creation science" violates the separation of church and state, both sides in the dispute were already sharpening the arguments for the next round of what promises to remain an escalating battle of wits.

In Washington, the National Academy of Sciences held the first meeting on Monday of a committee made up of prominent scientists and legal advisers who will prepare a legal brief on the scientific status of the theory of evolution to be presented by the academy as an *amicus curiae* ("friend of the court") document, either to the Arkansas court if there is enough time, or in any future legal proceedings.

Meanwhile the creationists are working on a revised version of their "model bill" used as the basis of the Arkansas law passed in March, requiring equal efforts to be devoted to teaching the theory of evolution and creation science in school biology classes. The new bill is designed to meet some of the legal challenges thrown up in the Little Rock proceedings and elsewhere.

Whichever way the Arkansas verdict goes, there is a good chance that the fight will make its way up to the Supreme Court. And the supporters of creation science are unlikely to be put off by an adverse legal ruling, since they claim to be backed by a groundswell of popular support.

The academy panel is being chaired by Dr James Ebert, vice-president of the National Academy of Sciences and president of the Carnegie Institution of Washington. Others on the panel include Dr Steven Weinberg, professor of theoretical physics at Harvard; Dr Preston Cloud, professor of biogeology at the University of California, Santa Barbara; and Professor Norman Newell, curator emeritus in the department of invertebrates at the American Museum of Natural History in New York.

Several legal experts have been included on the panel to advise on the constitutional issues raised by the creationists. These include Mr Peter Barton Hutt, previously general counsel of the Food and Drug Administration, and Dr Richard Maserve, a staff member of the Office of Science and Technology Policy under the Carter Administration. Both are now members of the Washington law firm Covington and Burling.

The legal brief will concentrate on providing an academy-endorsed statement on the definition of science which, it is hoped, will help both courts and state legislatures distinguish the philosophical status of the theory of evolution from creation science.

The academy is also considering

producing a booklet to summarize current thinking on evolutionary theory.

The main claim being put forward by the state attorney general, Mr Steve Clark, in Little Rock is that, since holes can be picked both in the theory of evolution as a conventional science and in creation science as a conventional religion, the two are "just as scientific" and "just as non-religious" as each other.

The American Civil Liberties Union (ACLU), which has filed the case against the state of Arkansas on behalf of several local religious groups and school teachers, has so far had no difficulty in generating substantial support, from both the legal and the scientific professions, in preparing its case. A prominent New York law firm for example has been providing free legal support — including extensive research and the services of eight back-up attorneys in Little Rock — which would normally cost many hundred thousand dollars.

"Next witness"

ACLU has received help and advice from between 60 and 70 scientists in preparing a brief. Among those called to the witness box who gave a vigorous defence of evolutionary theory and challenged the claims of creation science were Professor Francisco Ayala of the department of genetics at the University of California in Davis, a member of the new National Academy of Sciences committee; Dr Gary Dalrymple, a geologist who is an associate director of the Western region of the US Geological Survey; and Harvard evolutionary biologist and historian Dr Stephen Jay Gould.

In contrast, although the state attorney general's office is presenting a number of scientists to put the creationist interpretation of human origins, few have significant standing in the scientific community. Attorney General Steve Clark complained last Thursday that several scientists had refused to testify in defence of the new law, suggesting that they had been subject to "peer group pressure".

Not all creationists have been happy with the way that their case is being handled. Two of the more prominent attorneys associated with the creationist movement, constitutional expert Wendell Bird and Virginia attorney John W. Whitehead, complained that they had been excluded from playing a major role in preparing a defence of the law, and that the state had therefore prejudiced its own chances of defeating the law suit.

Both, however, are now preparing for the legal battles that lie ahead. And even if ACLU wins in Little Rock — as seems likely, given the liberal background of Judge William Overton and the way he has handled the case so far — next time round the arguments could be tougher to defeat.

One passage in the Arkansas bill, for example, speaks of creation science being based on the explanation that the world was created ex nihilo, a passage which theology professor Langdon Gilkey of the University of Chicago described as "the most religious" of various statements implying the involvement of a God, since "there are no other sources at work". The new version of the model bill, however, which is being circulated by Mr Paul Ellwanger of Citizens for Fairness in Education of South Carolina, merely states that creation science must be based on 'evidences that indicate creation of the Universe, matter and energy suddenly".

Given the fact that challenges from creationists are unlikely to evaporate, even if they lose the Arkansas case, ACLU is asking the judge for a "finding of fact" that any science must be based on natural laws and must be explanatory, falsifiable and tentative, criteria which they hope will rule out creation science as a genuine science, however it is described.

#### UK cancer research

### **Unequal shares**

If the Medical Research Council's (MRC) reshuffle in the allocation of funds for cancer research in Britain was intended as a bid to save money, it has been largely unsuccessful. The complete withdrawal of financial support from two cancer research institutes in Manchester and Glasgow has saved the council a paltry £0.5 million.

Instead, it seems, the changes - announced last month in the council's annual report — were aimed at a rationalization of administration in the Patterson and Beatson cancer research institutes in Manchester and Glasgow. Since 1970 the two independent laboratories have been financed by a joint committee of the Cancer Research Campaign (CRC) and the MRC, with the two bodies taking equal financial responsibility. "The MRC's decision to relinquish financial commitment to the CRC," says Dr John Paul, director of the Beatson laboratories, "has made administration here much easier. Working for two paymasters can become complicated.

The Beatson and Patterson laboratories may benefit from dependence on the publicly-supported CRC, but the Institute of Cancer Research in London (ICR) is left as pig-in-the-middle. It had been hoped

#### Painful adaptation at cancer institute

The problems of the British Institute of Cancer Research (ICR) stem largely from the events of four years ago, when its funds were substantially cut and put on a basis unusual for a British institute. The block grant to ICR has been tapering away for the past few years. From next April, research groups will have to compete exclusively for funds with other applicants to the Medical Research Council and the Cancer Research Campaign. To make matters more complicated, block funding of laboratory services has now also been withdrawn so that, for example, a research group which needs electron microscopy is now expected to obtain sufficient funds to pay for it as a properly costed service; consequently ICR will be able to maintain an electron microscopy facility only if there is sufficient demand and cash from the research units to support it continually.

Worse still, in the period between the sudden early retirement of the previous director of ICR, Dr Thomas Symington, in August 1977 and the appointment last year of Dr Robin Weiss, little had been done to adjust to the new circumstances. Indeed, ICR had gone on spending almost as though its total funds had not been cut by about 18 per cent, with the result that Dr Weiss inherited a deficit of about £1 million even though the Imperial Cancer Research Fund had donated about the same amount to help stave off the day of reckoning.

Since his arrival, Dr Weiss has had to clear the £1 million deficit and adjust to an annual budget that is now about £6.5 million — £4 million from the Medical Research Council and the Cancer Research Campaign, the rest from legacies, the National Health Service, endowments and granting bodies. About £400,000 a year has been saved by early retirements, the freezing of

vacancies and other means — for example, ICR no longer has laboratory cleaners. (Has anybody noticed?) About 45 members of staff have gone, a loss offset because Dr Weiss, with separate funds linked with his appointment, has brought in about 20 new people to establish a core of molecular and cellular geneticists.

But now, Dr Weiss and his newly appointed deputy director, Dr Tony Davies, have to find more savings. Unless some means can be found to spread the contraction over four years or so, by which time more natural or voluntary retirements will have done the trick, it looks as if there will have to be perhaps 50 compulsory redundances.

One immediate threat is to the Division of Tumour Immunology under Professor Peter Alexander at the Sutton branch of ICR. As a result of recent site visits, the Medical Research Council and the Cancer Research Campaign have very substantially cut the funds of this division, leaving uncertain the future of all the tenured staff.

Dr Weiss is not convinced of the justification of this drastic cut when he sees little or no evidence that either the council or the campaign is cutting back on tumour immunology in their own units. By similar reasoning, he also fears for the future of radiobiological research at ICR. With the Medical Research Council about to continue its large Radiobiology Unit under a new director, and with the Cancer Research Campaign committed to its Gray Laboratory in Northwood. Dr Weiss wonders if they will see fit to continue support for radiobiology at ICR, in spite of its good record and close links. with clinical radiotherapeutics. Dr Weiss holds that the institute is better placed to integrate radiobiology with other research activities than other establishments. Peter Newmark

that the MRC could allocate further funds to the ICR because of its divorce from the other two laboratories. But in practice the council has stepped up its commitment to the ICR by just 10 per cent, leaving the funding shared 60:40 with the CRC. This year the council also gave the institute £0.5 million for equipment, but this cannot be guaranteed in the future, says the MRC.

Dr Robin Weiss, ICR director, maintains that the reshuffle has had no immediate effect on the institute. But he is concerned about the future: "With the present arrangement of joint funding, I sometimes worry that we become neither's ultimate responsibility."

In this financial crisis, it would seem logical to predict that the CRC would be loyal to its wholly CRC-funded bodies and that the MRC's responsibility would rest preferentially with its own units. That

leaves the ICR in a rather vulnerable position. For there is no agreement, says Dr Weiss, that the financially healthier CRC should make good where the MRC falters.

Perhaps, though, the concern of the ICR for its future stems from its rough ride through the cuts of 1977. And the MRC is not last to admit that the financial status of the institute is far weaker than that of the Beatson or Patterson laboratories.

And while the CRC and MRC swear allegiance, one message emerges loud and clear, affirming Dr Weiss' concern. The CRC, dependent as it is on finance from the public, can in no way guarantee to act as back-up to the MRC with its government funding under continual threat. It is understandable that the ICR, funded by both bodies, should look nervously towards future government cutbacks.

Susan Douglas

### **NIH** guidelines

Sir - Comments are invited on two proposals for a major revision of the US National Institutes of Health (NIH) guidelines for research involving recombinant DNA molecules. The recombinant DNA Advisory Committee (RAC) has developed a proposed revision and recommended that it be published for comment. This proposal appears in the Federal Register dated 4 December 1981. The major features of this proposal are:

- (1) The guidelines would cease to be mandatory and would become a voluntary code of standard practice. The following requirements would be eliminated: that institutions have an Institutional Biosafety Committee (IBC), that investigators obtain prior approval from the IBC before beginning certain experiments and that investigators obtain prior approval from NIH before beginning certain experiments. The section of the guidelines specifying that noncompliance could lead to loss of NIH funds would also be eliminated.
- (2) Section III of the guidelines giving containment levels would be greatly simplified, and most experiments currently requiring P2 or P3 containment would be recommended at P1.
- (3) The prohibitions section (I-D) of the guidelines would be eliminated, although two of the current prohibitions (I-D-2 and I-D-5) would be retained as admonishments. An alternative proposal appears as item 7 in the Federal Register notice of 7 December 1981. The major features of the proposal are:
- (1) The guidelines would continue to be mandatory for institutions receiving NIH funding. Certain experiments would require prior review by NIH. Certain experiments would require prior review by IBC, and certain experiments would require notice to an IBC simultaneously with initiation of the
- (2) Section III of the guidelines would be reorganized and simplified. All experiments would fall into one of four classes. Physical containment requirements for some classes of experiments would be lowered.
- (3) Three of five current prohibitions (I-D-2, I-D-4, and I-D-5 in the current guidelines) would be listed in a new section that would continue to require RAC review and NIH approval before initiation. Experiments currently falling under prohibition I-D-1 and I-D-6 could proceed after IBC approval.

Copies of the above-mentioned Federal Register notices as well as a summary comparing the current guidelines with the two proposals are available from the NIH Office of Recombinant DNA Activities. Comments on these proposals should be directed to the attention of the Director, Office of Recombinant DNA Activities, National Institutes of Health, Building 31, Room 4A52, Bethesda, Maryland 20205, USA. These proposals and comments on them will be considered by the RAC at its next meeting on 8-9 February 1982.

### Laotian postscript

SIR — The clandestine US war against Laos during the Second Indochina War was for the United States substantially an air war - in terms of environmental impact almost entirely so. Its operational aspects have been well described1. Laos received more than 2.2 million tonnes of air-delivered munitions, fully 31 per cent of the US air war against all Indochina<sup>2</sup>. The massive wide-area saturation bombing from B-52 stratofortresses alone ultimately added up to 800,000 tonnes of bombs, accounting for 36 per cent of all such missions flown during the war throughout Indochina. The air war against Laos was carried out during the years 1965-73; the three peak years were 1969-71, which were almost equally intense and together accounted for 68 per cent of the Laotian total. An estimated 70 per cent of the entire US air assault upon Laos was in southern Laos (the panhandle), carried out primarily against the supply routes into South Viet Nam (the Ho Chi Minh trail). The remaining 30 per cent of the bombing was directed against northern Laos, to a major extent against the Plain of Jars in central Xieng Khouang province.

Herbicidal chemical warfare attacks by the United States during the Second Indochina War were at one time or another directed against all four of the Indochinese nations of the time, overwhelmingly so against South Viet Nam and in only small but unknown amounts against the others. However, the United States has recently released some relevant information regarding Laos<sup>3</sup>. During

the years 1965-69, the United States flew some 100 anti-plant missions (over 400 sorties), with 1966, the peak year, accounting for 76 per cent of them. Altogether 1,600 cubic metres of herbicides were dispensed, mostly (83 per cent) Agent Orange. This Laotian spraying thus represented 2 per cent of the total Indochina effort. The area sprayed was some 67,000 hectares (not counting overlap), 0.2 per cent of the area of Laos. Most by far of this spraying occurred in southern Laos; and most of the spraying was for purposes of forest destruction to expose the Ho Chi Minh trail. A very small but unknown amount of the total spraying (perhaps 3 per cent, the proportion of Agent Blue dispensed) was devoted to crop destruction in the Plain of Jars and possibly elsewhere

The Plain of Jars was especially hard hit during the war in terms of both social and environmental upheaval4 and is recovering extraordinarily slowly<sup>5-8</sup>.

### To trans, trans, trans-tricyclo [7,3,1,0<sup>5,13</sup>] tridecane

SIR - We are investigating the mechanisms of reactions of organic compounds in solution, in particular the relationship between a compound's reactivity and its molecular shape. We have prepared a number of new compounds, and the most recent of these has an especially pleasing shape and symmetry.

To celebrate this, we thought that a new form of reporting serious scientific results was appropriate, and the sonnet (Elizabethan rather than Petrarchan) seemed worth investigating. A fuller report, not in verse, is to be given today (17 December) at the Scottish meeting of the Perkin Division of the Royal Society of Chemistry at Strathclyde University.

Shall I compare thee to a single form Of cyclohexane locked with bulky group? Or should it be with that bicyclic norm Whose ethane bridge 1,5 doth fix the hoop?

Thy undistorted, perfect, trans-fused rings By force field calculation hold no strain: No rapid rates which angle bending brings As in bicyclo [3,2,1] octane.

Some help thy ground state conformation needs To free an equatorial tosylate, So ring-flip from an all-chair form precedes Reaction from a boat transition state.

And then departs the leaving group when trans Coplanar hydrogens the rate enhance.

# NEWS AND VIEWS

# DNA supercoiling by DNA gyrase

from L. Mark Fisher

THE enzyme DNA gyrase is essential for bacterial viability and plays a critical role in DNA replication and repair, transcription and recombination. Since last reviewed in these pages<sup>1</sup>, gyrase has been the subject of intense study and we are now beginning to understand how it carries out its function of catalysing the ATP-dependent introduction of negative supercoils — a coiling of the DNA helix axis itself — into circular duplex DNA.

Supercoiling can be understood in the following way. In linear duplex DNA, the two antiparallel DNA strands form a righthanded helix with about one helical turn for every ten base pairs - the B configuration. If the DNA is in the form of closed circles and has the same helix pitch as in the B configuration it is said to be relaxed. If, however, the two strands of the duplex circle are intertwined fewer times than in the relaxed circle, the DNA minimizes its departure from the energetically favoured B configuration by coiling about its helix axis (see Fig. 1). The degree of this supercoiling depends on the difference between the linking number (the number of times the two DNA strands are intertwined) of the DNA circle and the linking number of the same DNA in the relaxed state. By convention, underwound DNA forms 'negative' supercoils while overwound DNA forms 'positive' supercoils.

The mechanical strain energy stored in negatively supercoiled DNA exerts a persistent torsional stress tending to unwind local regions of the DNA double helix (Fig. 1). Thus, negative supercoiling catalysed by gyrase facilitates processes that entail unwinding of the helix, for example, at replication forks, during transcription and in the DNA strand transfer reactions involved in DNA recombination.

Gyrase belongs to a group of enzymes called DNA topoisomerases that change the linking number of circular DNA. They act by temporarily breaking and then reforming DNA phosphodiester backbone bonds. For all topoisomerases, transient DNA breakage is thought to proceed via the formation of a covalent enzyme–DNA intermediate that conserves the bond energy of the broken DNA phosphodiester bond for later rejoining. Topoisomerases

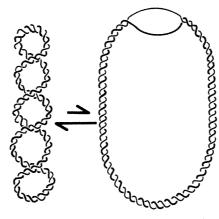

Fig. 1 Underwound circular duplex DNA (shown schematically on the right) forms negative supercoils (left).

are of two types, depending on whether they transiently break one DNA strand (type I) or both strands (type II)<sup>2</sup>. The omega protein of *Escherichia coli* is an archetypal type I enzyme and the eukaryotic nicking-closing enzymes also belong to this class. In contrast, gyrase, phage T4 DNA topoisomerase and some recently discovered eukaryotic topoisomerases are type II enzymes<sup>2</sup>. Gyrase is unique in catalysing DNA supercoiling: all other topoisomerases examined so far catalyse the removal of DNA supercoils, that is, they 'relax' DNA.

Two lines of evidence indicate that gyrase acts by making an enzyme-bridged transient double-strand break in DNA and passing another duplex segment through the break. First, gyrase can tie and untie knots in duplex DNA and can mediate the formation and resolution of catenated (interlocked) duplex DNA circles2-4. Second, both the supercoiling and ATPindependent relaxing activities of gyrase change the linking number of the substrate DNA in steps of two4.5. This result is precisely that expected from passage of one duplex DNA segment through another (Fig. 2). Type I topoisomerases change the linking number of circular DNA in steps of one, consistent with mechanisms involving

L. Mark Fisher is in the Department of Biophysics, King's College, University of London.

single-strand breakage of DNA5.

How does gyrase catalyse DNA breakage? Information regarding this question has come from studies using the gyrase inhibitor, oxolinic acid. In the presence of the drug, E.coli gyrase forms a complex with DNA that on disruption with a detergent induces double-strand DNA cleavage at specific sites<sup>6,7</sup>. Breakage of complementary DNA strands occurs with a 4 base pair (bp) stagger and results in covalent linkage of the two A subunits of the A2B2 gyrase complex, one to each 53 phosphate end of the break8-12. The A protein-DNA linkage is via an O<sup>4</sup>-phosphotyrosine bond, the same linkage used by some type I topoisomerases in attaching to DNA11,13. Thus, the gyrase A subunits are presumably engaged in breaking and resealing the DNA during catalysis, whereas the B subunits, known to bind ATP, participate somehow in energy transduction. Although the DNA sequences of many gyrase cleavage sites have now been determined, no readily apparent sequence rule governing cleavage has been uncovered8-10

The work of Liu and Wang showed that when gyrase binds to DNA, there is a positive superhelical wrapping of DNA on the outside of the enzyme<sup>14,15</sup>. Thus the gyrase-DNA complex resembles in part the nucleosome formed between histones and DNA, in which the DNA is known to be on the outside of the histones, although wrapped with a negative superhelical sense. Recently, detailed structural information about the gyrase-DNA complex has been obtained by several groups using nuclease protection methods<sup>9,10,16</sup>. These studies made use of specific gyrase binding sites on DNA, which were identified using the oxolinic acid cleavage reaction, or in the case of Micrococcus luteus gyrase, by a DNA binding assay. Gyrase bound at these sites protects 100-140 bp of DNA against DNase I, contained within the 143 bp of DNA protected against staphylococcal nuclease<sup>15, 17</sup>. Protection is observed both in the presence and absence of oxolinic acid. A 40 bp region encompassing the oxolinic acid cleavage site is most strongly protected. Assuming that gyrase cleavage sites are sites of transient DNA breakage

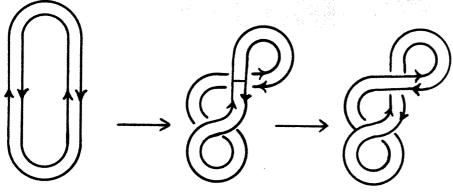

Fig. 2 Passage of one duplex DNA segment through another changes the linking number of circular duplex DNA in steps of two. A circular duplex DNA of unique linking number (left) is folded (centre) bringing together two different segments of DNA helix. Breakage of both strands of one helical segment, passage of the second helical segement throught the break followed by resealing generates a DNA molecule (right) differing by two turns from the starting DNA. Thus, strand passage has changed the linking number of the DNA by two.

during catalysis, then this 40 bp segment presumably forms part of the gate through which the second DNA duplex is passed. Protected DNA flanking this region contains sites of enhanced DNase I sensitivity spaced on average 10 or 11 bp apart, in a pattern similar to that observed for DNase I digestion of nucleosomal DNA. This result is diagnostic of DNA adsorbed to a surface and indicates that DNA flanking the cleavage site is wrapped around the outside of gyrase.

Several related models incorporating double-strand DNA breakage have been advanced to explain how gyrase supercoils DNA. All of the them embrace the following basic scheme. First, gyrase binds to DNA resulting in a positive wrapping of DNA around the enzyme and the formation of a compensating negative turn elsewhere in the DNA. ATP binding allows transient DNA breakage and passage of a second DNA segment through the break into the enzyme complex. The break is sealed and then ATP hydrolysis promotes release of the translocated DNA segment ready for another cycle. This sequence of events has been deduced in part from the finding that the non-hydrolysable ATP analogue ( $\beta$ ,  $\gamma$ -imido)ATP promotes only a single cycle of DNA translocation<sup>18</sup>. Wang et al. suggest that the positive superhelical wrapping of DNA on gyrase is retained during catalysis and that the translocated DNA segment can be anywhere in the nearby DNA19. Mizuuchi et al.4 and

Morrison and €ozzarelli<sup>16</sup> propose that the translocated DNA segment is directly contiguous with the wrapped DNA. Strand passage then results in conversion of the wrapped positive DNA turn on gyrase directly into a negative turn, thereby accounting for the directionality of the supercoiling reaction. It is unknown how the DNA duplex passed into the gyrase-DNA complex during catalysis is subsequently released. The DNA could be shuttled along an interface between gyrase subunits ultimately emerging from the gyrase complex at a location different from its entry point<sup>4, 19</sup>. Alternatively, a single entrance/exit port could be used, in which case, release of the passed DNA would require prior unwrapping of the resealed cleavage site16. These problems await clarification.

Type II enzymes have recently been isolated from eukaryotic cells2, 20, 21. Like T4 DNA topoisomerase, they do not supercoil DNA but act as ATP-requiring DNA relaxing enzymes. Intriguingly, they use ATP even though the removal of DNA supercoils is favoured thermodynamically. The biological functions of eukaryotic type II (and type I) topoisomerases remain to be elucidated.

### **Site-specific recombination**

from David Sherratt, Avril Arthur and Paul Dyson

GENETIC RECOMBINATION can conveniently be divided into two types distinguished by the extent of the DNA homology in the region of recombination. Homologous (or generalized) recombination occurs efficiently only between regions of DNA having at least several hundred homologous base pairs whereas non-homologous (or illegitimate) recombination occurs at regions of little or no homology. At least in Escherichia coli these recombination types are also distinguishable by the enzymes required: in vivo and in vitro experiments show that the RecA protein is directly involved in homologous recombination, whereas nonhomologous recombination is RecA independent and is often promoted by proteins whose genes are adjacent to the recombination site. Non-homologous recombination can be accompanied by DNA replication, for example in genetic transposition, or can simply be a conservative reciprocal breakage and reunion of DNA strands as first proposed by Campbell for bacteriophage  $\lambda$  site-specific recombination in 19622,3.

Several recent publications show that site-specific recombination is utilized in prokaryotes for a variety of functions, and though different systems show some similarities, their underlying molecular mechanisms may differ to allow efficient execution of their normal biological functions. The different possible outcomes of reciprocal recombination are schematically outlined in Fig.1, which also gives some indication of the activities and preferred directionality of the systems to be described here.

Bacteriophage  $\lambda$  integration and excision is the archetype of site-specific recombination and Campbell's model has been elaborated and substantiated by a wealth of elegant biochemical and genetic data<sup>4-6</sup>. Integration of  $\lambda$  in vivo requires  $\lambda$ int protein and normally occurs between attP, a region of about 240 base pairs (bp) on  $\lambda$ , and attB, a region of some 25 bp on the bacterial chromosome, generating two hybrid sites attL and attR. Though attP and attB are non-identical, they share a 15 bp homologous 'core' sequence within which recombination occurs. The reverse recombination reaction, between attL and attR, which leads to  $\lambda$  excision in vivo, requires both int protein and a second  $\lambda$ protein specified by the xis gene. In vitro, int promoted recombination occurs on negatively supercoiled DNA molecules containing both attP and attB, with little or no loss of supercoiling, no net DNA synthesis and no need for an exogenous energy source such as ATP. However, The authors are in the Genetics Department,

University of Glasgow.

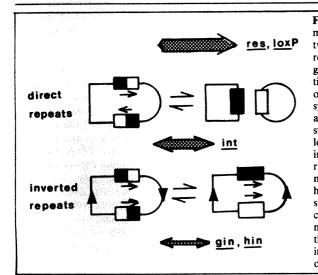

Fig.1 Consequences of intramolecular recombination between direct and inverted repeats. The hatched arrows give some indication of the activities and preferred directions of the different recombination systems. Whereas int protein acts on all combinations of substrates, Tn3/yô res and P1 lox appear primarily to act intramolecularly on directly repeated substrates. The normal biological function of hin and gin is to act on inverted substrates. Note that if any recombination sites are symmetrical, that is, palindromic, then repeats of them would be in both direct and inverted orientation.

there is a requirement for a host-protein complex, though int-protein alone has topoisomerase activity, that is, it can mediate breakage-reunion reactions.

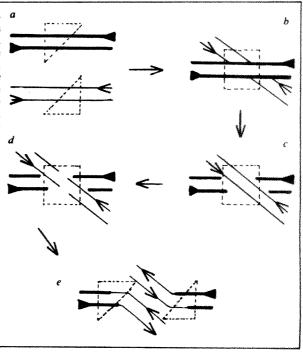

In contrast to λ-mediated site-specific recombination which can occur both intermolecularly (during normal integration) and intramolecularly (during excision), some other site-specific recombination systems, that have very different biological functions, usually operate intramolecularly at sites of fixed orientation. For example, in bacteriophage Mu, the expression of either of two different host ranges is specified by the orientation of an invertible segment of DNA bounded by a short inverted repeat. An adjacent gene, gin, specifies a recombination enzyme that acts at these repeats to mediate the inversion7. A closely related (and interchangeable) enzyme (hin protein) can similarly invert a l kilobase (kb) region of the Salmonella typhimurium chromosome by recombination across a 14 bp repeat to determine which of two flagellar types is synthesized?. In contrast to these two examples, where site-specific recombination acts to invert a sequence (exerting a 'flip-flop' phenotypic control), two other systems preferentially act on molecules containing directly repeated copies of the recombination site (Fig.1). Bacteriophage P1 exists as a plasmid in its lysogenic state and has a site-specific recombination enzyme which rapidly converts any dimeric plasmid molecules (generated during replication or homologous recombination) to monomers, by intramolecular recombination at a specific site, loxP8. It is postulated that such recombination may be important for stable maintenance of P1 as a plasmid, since its copy number control is so stringent that P1 replication is inhibited once there are two P1 replication origins in a cell. A single P1 dimer cannot be partitioned to both daughter cells.

Transposons of the Tn3 family also specify site-specific recombination systems that act most efficiently on directly repeated copies of the recombination site (res) within the same molecule<sup>9-11</sup>. Such molecules are generated in the first step of

intermolecular transposition of these transposons and are rapidly resolved to the normal transposition end products by the site-specific recombination. Two recent papers by Reed and Grindley<sup>12,13</sup> characterize the essentials of the reaction in vitro for one Tn3 family member, yô. The only requirements are the recombination protein (resolvase), Mg2+ and a negatively supercoiled circular DNA molecule containing two directly repeated copies of res. Although relatively large amounts of resolvase are required, the substrate is rapidly converted to the in vitro reaction products, two interlinked circles. In the absence of Mg2+, a limited reaction occurs in which a resolvase-DNA complex accumulates. Removal of the protein from the complex with protease leads to the appearance of linear DNA fragments that are the result of double-strand breaks at each of the res sites. The breaks are staggered, having two nucleotide 3' extensions, and have remnants of the resolvase bound to the 5' ends. Formation of such fragments depends on two res sites being present in the same DNA molecule, indicating that the breakage reaction can only be initiated on formation of a complex of resolvase bound to two res sites. If these resolvase-DNA complexes are subsequently incubated with Mg2+, then some of them are converted to the normal in vitro products, supporting the idea that the staggered breaks are intermediates in the recombination. It therefore seems that yo resolvase, like known topoisomerases, can conserve polynucleotide chain phosphodiester bond energy generated during strand breakage and use it for subsequent strand rejoining. Although similar intermediates have not been reported in the  $\lambda$ int-promoted reaction, experiments have shown that five or seven nucleotide staggered breaks with 5' extensions occur during such recombination5.

Nash and co-workers have suggested that during & recombination the two homologous 'cores' come together to form a four-stranded structure stabilized by intermolecular hydrogen bonds, a structure originally proposed by McGavin<sup>14</sup>. The int protein-promoted nicking of a single strand at the same position on each duplex could allow rotation around the uncut strands to bring broken ends adjacent to their recombinant partners, where ligation occurs. Subsequent nicking, rotation and ligation of the other two strands would produce recombinant DNA6. Though such a model is consistent with the type I topoisomerase properties of int protein, strand rotation appears not to be an inherent property of typical topoisomerases15. Reed's and Grindley's observations that γδ resolvase can generate a double-strand cleavage could mean that this enzyme acts like a type II topoisomerase, the recombination occurring as one cleaved res site undergoes strand passage through the

Fig.2 A model for res recombination. (a) Two regions of DNA each containing at least a dimer of resolvase bound to res sites, (b) protein interactions bring the two res sites together and now (c) double-strand cleavage of one of the helices occurs and a double-strand passage event is initiated, as during type II topoisomerase action 15. Strand separation and rotation are prevented by bound enzyme. During the strand passage, the second cleavage occurs (d) and is immediately followed by ligation to produce recombinant DNA. Though interlinking of helices to give catenanes will arise from accidental interwinding of DNA segments that will eventually reside in different recombinant products6, it could occur during strand exchange at the

second (Fig.2). Such a mechanism would implicate resolvase protein rather than four-stranded DNA both in initial synapsis and in the maintenance of superhelicity during recombination.

As more information becomes available it is becoming clear that despite similarities in these recombination systems, they have evolved diverse biological roles. For example, whereas the \(\lambda\) int, Tn3/y\(\delta\) res and P1 lox systems may need to act very rapidly, inversion in the gin and hin systems occurs relatively rarely. This is to be expected, since there would be little sense in rapid switching from one host range or flagellar type to another. The relative efficiencies of these systems may reflect both the activities and amounts of the recombination enzymes and the nature and position of the normal recombination sites. Because the energy states of the reaction substrates and products ought to be very similar, the presence of a functional site-specific recombination system should generate an equilibrium mixture of similar quantities of reactants and products. Though this appears to be the case for the inversion in the 'flip-flop' recombination systems, the other systems have evolved ways of apparently shifting this equilibrium. If  $\lambda$  excision were simply a reversal of integration, then establishment of stable lysogeny would be difficult or impossible. The asymmetric  $\lambda$ recombination sites (attP and attB) generate different integration and excision substrates, which in turn allow the additional xis protein to be required for excision. At first sight, the Tn3 and yô sitespecific recombination reactions appear as if they should be readily reversible: in a molecule containing two directly repeated transposons there is at least 5 kb of homology surrounding the res sites, yet though such a molecule is an excellent recombination substrate, the reverse reaction to join two separate molecules through res recombination appears very infrequent. Perhaps even more surprising, res recombination in vivo or in vitro acts poorly on inverted copies of res in the same molecule. In contrast, λ int protein can act on attP and attB in all configurations (Fig.1). We presume that topological considerations may determine the very different efficiencies with which res recombination takes place on the different substrates. DNA topology is likely to be important in control and determining specificity in many biological systems.

# A plasma wake for Mars' satellite Deimos

from Alan Johnstone

SUCH diverse topics in space physics as the formation of the Earth's magnetosphere and the electrical charging of spacecraft can be gathered together under one heading — the interaction between a plasma and a moving body. The physical processes involved are quite varied and depend on the size of the body and its physical characteristics.

Although some experiments have been carried out in the laboratory, the conditions in space cannot be modelled accurately. Empirical knowledge of the interactions in space is therefore limited to observations of naturally occurring cases where the parameters cannot be varied in controlled conditions. Fortunately, the exploration of the Solar System in the last decade has revealed an unexpectedly rich variety of examples which cannot even be listed in a short article. Now, yet another one has been discovered. One of the martian satellites, Deimos, which is only 15 km across its largest dimension, is believed to create a disturbance in the solar wind which is 5,000 km across, 15,000 km downstream from the object (Bogdanov J. geophys. Res. 86, 6926; 1981).

The solar wind is an extremely tenuous gas of positively and negatively charged particles [10 per cm<sup>3</sup>] flowing outwards from the Sun at hypersonic speeds (400 km s<sup>-1</sup>). The Russian spacecraft Mars 5, in orbit around Mars, found a region where the plasma density was lower than in the solar wind, the velocity was slower and the temperature higher at a time when the spacecraft was well upstream from any interaction with the planet itself. Another spacecraft, Mars 4, one million kilometres upstream from Mars at the same time, and which normally measured the same plasma parameters 20 minutes earlier than Mars 5, did not encounter a similarly disturbed region nor did it observe a variation in solar wind conditions which could have caused the martian bow shock to have formed in an unusual position upstream. Throughout its passage through the disturbed plasma Mars 5 continued to measure the same strength and direction for the magnetic field as it had in the solar wind.

When the solar wind encounters a solid body which absorbs the particles that strike it, like the Moon, then it simply leaves a wake little larger than its diameter extending tens of diameters downstream. If Deimos created the effect observed by Mars 5 it must interact more strongly than this. If the body deflects the particles, and if there is a strong enough force between the particles to organize their motion in a collective way, then the solar wind will flow around the body with a fluid-like motion, thereby creating a much larger disturbance downstream. Since the average distance between collisions is greater than the distance from the Sun to the Earth, it cannot be a fluid of the type we know in everyday life. In fact, the magnetic field frozen in the plasma organizes the motion and is strong enough when the gyroradius of the ions is small compared with the scale length of variations in the flow. The solar wind can be deflected by a magnetic field but, since the gyroradius in the solar wind is about 100 km, Deimos would need a relatively large dipole moment to create an obstacle capable of deflecting the solar wind as a fluid. If Mars 5 had crossed a magnetic tail from Deimos then the magnetic field should have been aligned antiparallel to the solar direction. It was actually at an angle of 70° to this direction, so it is unlikely that the interaction is magnetic.

The flow can also be deflected by an atmosphere, as at Venus. There the upper atmosphere is ionized by sunlight and induced currents deflect the solar wind. The gravitational field of Deimos is far too weak to hold a permanent atmosphere but if there is a continuous outgassing from the surface then the density of the outwardflowing gas could perhaps be sufficient. The molecules do not interact with the solar wind until they have been ionized either by sunlight or by charge exchange. The interaction suggested by Bogdanov is one where the thermal pressure of the electrons created by photoionization is sufficient to balance the solar wind pressure. In order to obtain a fluid-like interaction the surface of pressure balance must be placed at least an ion gyroradius from the surface. The outgassing rate required to achieve this would result in the loss of one-third the mass of Deimos in a billion years. The outgassing could therefore be sustained for a period comparable with its lifetime.

Bogdanov compares this process with the interaction between a comet and the solar wind. Water, carbon dioxide and other volatile compounds sublime from the surface of the comet's nucleus as it is heated during its passage near the Sun. As this gas flows outwards from the nucleus it creates most of the familiar visible features associated with a comet. The outgassing rate from Deimos, required by Bogdanov's theory, is only one-millionth that of a large

Alan Johnstone is in the Department of Physics and Astronomy at University College London.

comet near perihelion so Deimos should not produce a large visible coma.

While Bogdanov's mechanism may be important near the body, the outgassing should be important over larger distances and near comets. When the neutral molecules are ionized by sunlight they are accelerated by the electric and magnetic fields up to the solar wind speed. This addition of mass to the solar wind flow requires a reduction in speed to conserve momentum. These implanted ions follow cycloidal paths around the magnetic field direction and would not be detected by particle detectors aimed at the solar wind. The radius of the wake is roughly equal to the average distance travelled by a gas molecule before ionization. This mechanism should produce a larger wake at a lower outgassing rate.

Clearly the observations make Deimos a more interesting body but whether Deimos is the cause of the disturbance and, if so, which mechanism is responsible can only be determined by more measurements from spacecraft.

# Thermal instability of solar loop structures

from Robert Rosner

THE past decade has seen a fundamental revision of our conception of the spatial structure of the multi-million degree plasma (corona) surrounding the Sun<sup>1,2</sup>. The change involves recognition of the dominant role of the magnetic fields, which pass outwards from the solar interior through the visible layers of the solar surface, in structuring the overlying coronal atmosphere into regions topologically 'closed' and 'open' to the interplanetary medium.

The consequences for theoretical models of the solar corona have been quickly realized, primarily in calculations based on simple hydrostatic models3,4 involving magnetic plasma confinement. In the past few years, the existence and stability of these equilibrium solutions to the hydrostatic equations of motion have been extensively studied<sup>5-8</sup>. The extreme nonlinearities of the problem make the temporal behaviour of the confined solar atmosphere very difficult to predict theoretically. Especially troubling has been a discrepancy between theory and observation: most theoreticians believed that unless thermal conduction from the coronal loop down to the solar surface was 'large', instability was inevitable (so that the loop atmosphere was then unlikely to be in a state approximating hydrostatic conditions8), but X-ray observations of the Sun showed that the confined multimillion degree solar corona had little difficulty in maintaining plasma conditions often observationally indistinguishable from a quiescent, stationary state<sup>2</sup>. The extent to which the predictions based on simple equilibrium loop models match the data is quite remarkable9. The disparity is of great general interest because related problems of thermal and magnetohydrodynamic stability have arisen in laboratory plasma studies and interstellar medium and extragalactic plasma astrophysics; the solar

Robert Rosner is at the Harvard-Smithsonian Center for Astrophysics.

corona thus provides a 'laboratory' in which plasma stability can be put to test. In a recent issue of Nature Craig and McClymont<sup>10</sup> show how a large part of this difficulty can be resolved by more realistic modelling of the low-temperature boundary layer separating the coronal loops from the visible solar surface.

The early work on stability focused on two distinct issues: assuming isobaric perturbations, first, are the equilibrium solutions stable if the base temperature is held fixed; second, are the equilibrium solutions stable if the base conductive flux is held fixed. The first case (A) would seem to be appropriate if the base is located sufficiently deep in the atmosphere so that coronal (or transition region) pertubations do not disturb local energy balance. The second case (B) is more complex: the conductive flux may remain fixed either at a fixed spatial location (with varying base temperature; case B.1), or for a fixed temperature (with varying base location; case B.2); the latter case is appropriate if the base of the loop is chosen to lie in regions where radiative processes can control the temperature rise (see ref. 11), so that the base takes on the character of a free surface whose spatial location may vary. It is not obvious which of these three alternatives is in fact followed by the Sun's atmosphere.

Results for case A (which assumes unvarying conditions in the underlying chromospheric plasma) showed instability was inevitable if the base thermal conductive flux was very small ('thermally isolated' case), but with growth rates sensitively dependent on the ratio of base to peak temperature<sup>5-7</sup>. The basic physics of the instability involves the strong destabilizing influence of radiative energy losses (which decrease with increasing temperature for coronal plasma temperatures), and the stabilizing effect of thermal conduction, much as discussed in the classic paper by G. B. Field<sup>12</sup>, but recast in the context of the strong inhomogeneities found in the solar

atmosphere (so that effects of boundaries, for example, must be taken into account).

In contrast, it has been argued that for case B.1, instability is inevitable, but that for case B.2 the stability of hydrostatic equilibrium solutions depends both on the ability of the loop base to adjust to coronal (or transition region) perturbations and on the response of the local heating process to imposed perturbations6.

Two very distinct approaches have been followed in trying to resolve this impasse. Recently, several groups have developed numerical time-dependent hydrodynamic codes which are capable of following the evolution of solar coronal structures; these studies follow the evolution of perturbed equilibrium models, and appear to conflict with much previous analytical work: imitating nature, the loop simulations show great robustness against perturbation<sup>13-15</sup>. The work of Craig and McClymont<sup>10</sup> avoids the necessity for such 'brute force' calculations by asking a simpler (yet crucial) question: can the earlier analytical results predicting strong instability for fixed conductive flux conditions be maintained if one takes into account the rapid temperature variation along magnetic field lines at the photospheric base of the coronal loop structures; specifically, can a change in the (de)-stabilizing properties of the radiative energy losses at low temperatures significantly affect loop stability? This question's relevance is clear from the earlier results, which typically showed that the denser and cooler portions of the loop atmosphere tended to control the instability time scale5.

Starting with a realistic radiative energy loss function (in particular, at low temperatures), Craig and McClymont proceed to calculate the linear growth rate of the most unstable mode for a model with a fixed, vanishing base thermal conductive flux (case B.1 above), as a function of the amount of low-temperature material included at the base of the model atmosphere. The basic result is that, in typical solar conditions, the instability time

scales for the unstable modes far exceed typical observed lifetimes (viz., days) of the loop structures in question; remarkably little low-temperature material is, in fact, required to quench the instability. Theory can thus now be fully reconciled with observation: if proper account is taken of the stabilizing influence of the boundary layer separating the solar corona from the underlying (visible) photosphere, analytical normal mode analysis does predict stability for time scales of the order of the observed coronal structure lifetime:

the error of previous calculations — and the source of the apparent discrepancy with observations — was simply the neglect of this stabilizing factor.

From both the observational and the theoretical perspectives, it thus now appears that the gross properties of the confined solar corona can be understood by considering simple hydrostatic equilibrium models, although the reasons for this are quite complex and, in some cases, are still not well understood9. However, when one looks at the corona in

some detail the simplicity disappears, and it is apparent that hydrostatic models are seriously inadequate. Observations of intensity fluctuations, of persistent up and down flows, of relatively cool matter residing at coronal heights, of apparent spatial mingling of hot plasmas at quite different temperatures, all call for more sophisticated modelling. Analytical methods seem inadequate for such modelling; the new plasma simulations have thus appeared at an opportune time.

## Hybridoma technology identifies protective malaria antigens

from F.E.G. Cox

VARIOUS partially successful attempts have been made to immunize experimental animals against malaria but preparations of the most easily obtained antigens, those derived from the forms of the parasite in the blood, have been relatively crude and poorly characterized. The use of monoclonal antibodies has now enabled scientists at the Wellcome Research laboratories to identify specific protective antigens and to use them to immunize mice against a virulent form of malaria1.

A vaccine against malaria is one of the prime needs in tropical medicine and in a variety of models in laboratory animals vaccines have been prepared from sporozoites, the infective stages injected by the mosquito; schizonts, the dividing forms in the red blood cells; and merozoites, the products of this division that invade fresh cells. Monoclonal antibodies have been used to identify an antigen with a molecular weight of 44,000 that completely envelops the sporozoite and induces immunity to the rodent malaria parasite Plasmodium berghei<sup>2</sup>. This antigen is specific to the sporozoite and seems to be a differentiation antigen that appears while the sporozoites are in the salivary glands of the mosquito and disappears soon after they have been injected by the mosquito and have entered the liver cells where they first phase undergo their multiplication3.

Although a sporozoite vaccine is a logical and feasible possibility and would prevent the parasite from developing in the liver and thence the blood, a number of workers feel that should a single sporozoite escape the immune response, infection of the red blood cells would eventually ensue and therefore a vaccine should be based on the blood stages. The most promising candidate is the merozoite, and injections of merozoite antigens combined with adjuvants have been shown to protect monkeys against several species of malaria parasite4.

A monoclonal antibody against merozoite antigens of the rodent malaria parasite, Plasmodium yoelii, is known to confer protection on passive transfer5 and it has now been used to identify the antigen involved1. The latter has a molecular weight of 235,000, is associated with an internal organelle of the merozoite and is specific to the merozoite. When mice were immunized with this antigen in Freund's adjuvant, they responded with high levels of merozoite-specific antibody and were protected from death following challenge, although they experienced relatively high parasitaemias lasting about 16 days. A second monoclonal antibody known to react with schizonts, but which was not protective on passive transfer<sup>5</sup>, was used to identify a second protective antigen. This is a surface antigen with a molecular weight of 230,000 which is present early in the maturation of the schizont and occurs on both schizonts and merozoites. Mice immunized with this antigen produced high titres of antibody against schizonts and were very resistant to challenge, experiencing only a mild infection lasting about 9 days. The significance of these results is that monoclonal antibodies can be used to identify protective antigens, but it is also interesting that the best protective immunity was produced in response to the antigen whose corresponding monoclonal antibody failed to provide passive protection.

What exactly is the nature of these antigens? Using similar virulent and avirulent forms of P. yoelii, Taylor et al.6 also have produced a range of monoclonal antibodies to sporozoites, schizonts and merozoites. Their antibody to merozoites was specific to merozoites but crossreacted with those of several species, was associated with an internal organelle possibly involved with penetration into the red blood cell but was not protective. Epstein et al.7, using Plasmodium knowlesi in monkeys, have obtained three hybridoma lines that produce monoclonal antibodies against merozoites. All three agglutinate merozoites and two block red cell invasion. The antigen involved has a

molecular weight of 250,000 (or 240,000 if saponin lysis of infected cells is used) and cross-reacts with various strains of P. knowlesi. A fourth group of workers (Perrin et al. 8) have also raised monoclonal antibodies to various stages including merozoites, this time to the human parasite, Plasmodium falciparum, in the mouse, a non-susceptible host. The merozoite antigens involved were surface polypeptides with low molecular weights, 36,000 and 96,000, and antibodies against these inhibited the development of P. falciparum in vitro. Antigens with low molecular weights like these must be viewed with caution, because Holder and Freeman also detected low molecular weight polypeptides associated with schizonts and concluded that they were proteolytic fragments of the 230,000 molecular weight antigen1.

Thus a number of potentially protective antigens on the merozoite have already been identified using monoclonal antibodies. Some are surface antigens and some are internal, some cross-react with other stages or the merozoites of other species and there is also variation in molecular weight. It is likely, therefore, that a number of antigens are involved in the immune response to the merozoite alone and these may operate sequentially, concurrently or alternatively. Antigens associated with schizonts1 and sporozoites2,3 have also been identified using monoclonal antibodies. It is going to be a long time before anyone identifies the most important protective antigens in a malaria parasite but in the meantime there will be a quantum jump from the use of crude homogenates as vaccines to cocktails of characterized polypeptides and these are much more likely to be acceptable in human medicine than anything in experi- $\Box$ mental use at the present time.

# Which direction for ocean drilling?

from J.R. Cann

A recent conference\* on ocean drilling (COSOD) enabled some one hundred and fifty geologists and geophysicists — including both those involved in the field as well as sceptics from other areas — to take a cool look at the long-term future of scientific drilling of the ocean floor. Of particular interest was the debate over whether the drillship Glomar Challenger should continue to be used or whether it should be replaced, at considerable expense, by conversion of the much larger Glomar Explorer.

Ocean drilling has been conducted since 1968 from the special dynamically positioned drillship Glomar Challenger, originally entirely USA funded, but expanded in the mid 1970s to include participation by the UK, France, Germany, Japan and the USSR. Currently the project costs \$21 million per year of which \$14 million is required to run the ship. The non-US subscription runs at \$2 million per year per partner, on top of which is the spending required to support the experiments connected with drilling.

Following a similar conference in 1976, plans were initiated to convert the six times larger Glomar Explorer from its original deep lifting role to a vessel for deep ocean margin drilling, carrying all the safety equipment necessary for drilling holes 6 km deep in water 3 km deep. Although at first it seemed that the Challenger and Explorer programmes might develop in parallel, progressively revised cost estimates showed that this was unlikely.

Scientific returns from Challenger increased in quality, especially with the development of the hydraulic piston corer that recovers almost undisturbed sediments from as deep as 200 m below the ocean floor, but financial pressures became greater. The planned Explorer drilling was too costly for the US Government to undertake alone, and under President Carter the joint government/oil company Ocean Margin Drilling Program was evolved. Eventually, after an initiative from the NSF to merge the two programmes, the oil companies withdrew from the Explorer program on 6 October this year. A number of detailed geophysical compilations for the areas selected for deep drilling (to be available next year) were carried out as well as various feasibility studies for the engineering involved. A Lockhead-Sedco venture is currently studying how best Explorer could be converted - without the expensive and complex safety systems necessary for really deep penetration in deep water.

\*The 'Conference on scientific ocean drilling' (COSOD) was held in Austin, Texas on 16-18 November, 1981. The steering committee is preparing a report which will be available in the spring. COSOD, which was originally conceived as coordinating the *Challenger*- and *Explorer*-based drilling programmes, was left with two principal tasks, both of greatest importance. One was to examine the scientific justification for drilling beyond 1983, and the other to consider, if drilling was to continue, whether using *Explorer* or *Challenger* would be best.

A. Shinn, newly appointed director of the Office of Scientific Ocean Drilling at NSF, set the framework from the NSF point of view. He pointed out four options: (1) to terminate all scientific drilling at the end of 1983, when *Challenger* finishes her current phase of operations; (2) to extend the *Challenger* program for up to five more years; (3) to convert *Explorer* to a *Challenger*-like ship and use her instead of *Challenger*; and (4) to convert *Explorer* to a ship fully equipped for deep penetration in deep water as envisaged by the Ocean Margin Drilling Program.

Option (1) he presumed, correctly, would be rejected by the conference, and option(4) he regarded as too expensive to support, leaving options (2) and (3). He indicated that running costs for *Explorer* would be similar to or somewhat more than those of *Challenger*, but that conversion of

Hairstar from the Taimur Coast. From Nature 25, 22 December, 181 (1881).

Explorer would put a halt to drilling (so that conversion could be funded) for about 18 months. He asked the conference to help decide between the two options, by assessing the ability of Explorer to handle larger amounts of drilling materials, to drill in high latitudes (especially in the Southern Ocean), to carry more scientists and to increase in drilling capability through a longer life, compared with the known and continuously available capability of Challenger.

A series of scientific reports and workshop discussions followed, including presentations from planning groups associated with both the present Challenger drilling and the Ocean Margin Drilling Program originally planned for Explorer.

On the final day the chairmen of the working groups presented their proposals to the reassembled conference, together with priorities for drilling. There were far too many proposals for excellent science than could be accommodated by one drilling ship. Among the highest priority targets presented, 'natural laboratories' was one watch word. These would consist of groups of holes in the ocean crust to study hydrothermal circulation, crustal construction and tectonics, which would act not just as sources of rocks for examination, but also as sites for in situ measurements and experiments, both in the short term and as long-term observatories. Work of this kind has already started, and shows great promise. Some holes would be sited on young, newly created crust where water at 350°C is seen to bring out sulphide ores from within the crust, and technical problems of drilling on bare, sediment-free rock, as well as at these very high temperatures, must be solved.

Testing the Vail Curve was another priority. This curve shows sea level in the geological past and was constructed by Peter Vail and his associates at EXON on the basis of seismic reflection profiles and drilling in shelf areas. Various aspects can best be tested outside traditional oil-producing areas, including the magnitude, suddenness and synchronism of the changes, and a number of such tests were proposed. If the Vail Curve can be made entirely reliable, then the consequences for understanding the geology of sediments would be great indeed.

Island arc regions, near the chains of volcanoes that border the Pacific and some other parts of the oceans, are places where plates are being subducted back into the Earth's mantle. They are still poorly understood, and are clearly of great importance in understanding global geology. Many kinds of targets were identified here, of which the most graphic is the drilling through the pile of sediments on the inner wall of ocean trenches into the descending plate of oceanic material,

J.R. Cann is Professor of Geology at the University of Newcastle upon Tyne. where experiments could be performed. If much of the oceanic sediment is swept down into the mantle here, as seems increasingly likely, this could have profound effects on the chemical balance of the Earth's interior

Palaeoclimates are inextricably linked with past oceanic circulation. In particular, the Antarctic regions carry the full record of glaciation and deglaciation, as well as an amplified record of pre-glacial climates. This is a prime target for any further drilling, but others too were identified in this area, such as the history of the vertical temperature and oxygenation structure of the deep oceans, and the nature of the great Pacific Ocean of 200 Myr ago. Only small fragments of this ocean crust remain, and these are buried deep beneath later sediments. However the Pacific then was even larger than today, and was essentially the only ocean, lying opposite the supercontinent of Pangaea.

Finally there is the problem of the origin of split continental margins, such as those bordering the Atlantic. Since these areas are closely associated with petroleum generation and might contain deep-water petroleum deposits, they are clearly worth drilling. To understand them you need to drill where oil companies will not — on margins where sediments are thin and the history is close to the surface. During last summer great advances were made in our understanding of these areas by *Challenger* drilling around the Bay of Biscay and Rockall Bank, and this work is to be extended.

Which would be best for all this drilling, Explorer or Challenger? The tools and techniques people presented a report which essentially said that you get what you pay for. Challenger could be upgraded in many ways at a cost of \$7.5 million, although she could not apparently be fully strengthened for work in ice. Explorer could be converted for drilling at a greater cost, but would have greater capabilities, especially if extra money was available. Some of the scientific targets, such as the bare rock drilling, would require extensive engineering development, while others could only be reached using a fully converted Explorer. An informal vote was called for among the scientists present to see the extent of the support for Explorer or Challenger, and a substantial majority felt that the potential of Explorer outweighed the know abilities (and restrictions) of Challenger.

The general view of COSOD was that oceanic drilling should be regarded as integral a part of earth science as radiotelescopes are of astronomy. Instead of the present situation, where continuation of drilling has to be fought for every two years, there should be a general expectation, as with telescopes, that funding will continue and that the great contributions made to earth science by drilling will continue at the same or higher levels over at least the next decade.

### Life seen from a medieval latrine

from Peter D. Moore

IF, as it is said, one can tell much about man's way of life from the contents of his garbage can, then one may indeed be able to tell even more from the contents of his latrine. It is perhaps surprising, then, that such depositories of environmental information have been rather neglected by archaeologists, despite their longestablished affinity for middens. There are exceptions, of course, such as the delvings of Pike and Biddle (Antiquity 40, 293; 1966) into the sewerage system of medieval Winchester in search of human gut parasites and Dennel's (Econ. Bot. 24, 151; 1970) analysis of plant macroscopic remains from a sewer in medieval Plymouth. In the New World less is known but nevertheless. Schoewetter (Archaeology of the Mammoth Cave Area, Academic Press, 1974) has been able to analyse the contents of sub-fossil human faeces in Upper Salts Cave, Arizona.

A golden opportunity to develop an interdisciplinary approach to the study of long-abandoned lavatories arose in Worcester in 1975 when the clearance of an area of housing for the development of a new road revealed the existence of the lower part of a medieval barrel latrine filled with organic material. The find was excavated by Greig and its contents analysed for beetles (Osborne), plant macrofossils and pollen parasites (Greigh), bones (Jones) and cloth (Crowfoot and Raphael). It was radiocarbon-dated to the mid fifteenth century and the work has now been reported by Greig (J. archaeol. Sci. 8, 265; 1981).

The beetle fauna was dominated by Tipnus unicolor and Mycetaea hirta, which Osborne considers to be characteristic species of the cesspit habitat. He comments that the scarcity of these species today contrasts strongly with their abundance in medieval times, no doubt a consequence of such developments as the water closet. Of the other 36 beetle taxa recorded, an intriguing find is Anobium punctatum, the furniture beetle or woodworm. It may be that this hapless insect inhabited the (presumed) wooden seat above the latrine and that it died on emergence, but Osborne considers this taxon to be something of a coleopteran 'background noise' in a variety of deposits and therefore of little significance. Other beetles are characteristic of stored grain, or vegetables, which suggests an admixture of kitchen refuse in the barrel. It is possible

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, University of London.

that such material could have been used for hygienic purposes together with the fragments of cloth and moss (tentatively identified as *Thuidium*) also found in the barrel.

Interpretation of the wealth of plant material found in the latrine is complicated by this input of extraneous vegetable matter. Undoubtedly some of the fruits and seeds found have passed through the human gut, such as Robus fruticosus (bramble - an unlikely candidate for hygienic uses), Fragaria (strawberry), Vitis (grape) and Ficus (fig). The figs must surely have been imported but it is possible that the grapes were locally grown. Many fruits and seeds were weeds of cultivation, or hedgerow species which could have found their way into collections of straw, indeed in the case of some of these, such as fennel (Foeniculum vulgare), coriander (Coriandrum sativum) and carrot (Dancus carota), it is difficult to be sure whether their origins are cultivated or casual. Certainly some of the seeds must be derived from the contaminant weeds of medieval crops, such as the corn cockle (Agrostemma githago), all species which have declined drastically in the present century with the advent of herbicides and whose demise is greatly mourned by the pestiphile lobby among conservationists.

Anyone who reads old herbals will be aware of the degree to which our forefathers were obsessed with the activities of their alimentary systems. It is natural, therefore, to look expectantly into the contents of the latrine in hope of finding direct evidence of the use of herbs. There are indeed some seeds of such plants as self heal (Prunella vulgaris) and black nightshade (Solanum nigrum), quite apart from the fig, of course. But some of the finds may give cause for concern, such as the deadly nightshade (Atropa belladona) and water dropwort (Oenanthe croccata) and hepbane (Hyoscyamus niger). In view of the toxicity of these species, one cannot help wondering what eventually befell the user of the latrine.

A sad, though predictable, feature of the analysis is the high concentration of parasite eggs *Trichuris* (whip worm) and *Ascaris* (roundworm), with the former predominating in the ratio 3:1. This reflects the generally poor living conditions and lack of hygiene at that time.

From the contents of this barrel, Greig has managed to piece together an intriguing and complex picture of everyday medieval life in Worcester and may have purged some of the disinclination to exploit the archaeological potential of such residues.

# Volcanic earthquakes at Pavlof Volcano correlated with the solid earth tide

S. R. McNutt\* and R. J. Beavan†

\*Department of Geological Sciences, Columbia University and †Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964, USA

Volcanic earthquake swarms at Pavlof Volcano, Alaska, correlate significantly with solid earth tidal stress rate for periods just before and just after explosive eruptions. The correlation changes sign systematically during the course of the 1974 minor eruption sequence; pre-eruptive earthquake swarms occur during increasing tidal compression, while post-eruptive swarms occur during increasing tidal extension.

IT has been proposed that the solid earth tide has a role in triggering both earthquakes and volcanic eruptions (see refs 1-5). Crustal stresses of the solid earth tide are of the order of 0.03 bar, with principal periods of ~12 h 25 min, 24 h 50 min, and 14.7 days, and constitute some of the largest pervasive short period oscillatory stresses in the Earth's crust<sup>6</sup>. We examine here the relationship between volcanic microearthquakes and the solid earth tide during the autumn 1974 minor eruption of Pavlof Volcano, Alaska. A correlation has been found between B-type<sup>7</sup> volcanic earthquake swarms and solid earth tidal stress for periods of 3-4 days before and after eruptions. The correlation changes sign systematically for time periods before and after the eruptions, corresponding to periods of presumed inflation and deflation of the volcano.

Pavlof is a 2,715-m high stratovolcano located near the end of the Alaska Peninsula at 55°25′ N, 161°54′ W. It is one of the most active volcanoes in North America with at least 27 documented eruptions since 1700 (S. Hickman, personal communication). Strombolian eruptive activity typically includes lava fountaining and flows, emission of steam and ash, and minor explosions. Analysed lavas are basalt, with small phenocrysts of plagioclase, olivine, hypersthene and augite<sup>8</sup>. The upper portion of the mountain is covered by glaciers.

Twelve seismometers are in operation near Pavlof (Fig. 1). BLH and PVV are stations of the Shumagin Islands regional network, operated since 1973 by Lamont-Doherty in cooperation with the University of Alaska. The remaining local network stations were installed by Lamont-Doherty in 1976, that is, after the sequence of eruptions discussed here. Most of the data presented here are from station PVV, a short period (1 Hz) vertical seismometer located adjacent to an old lava flow 7.5 km south-east of the volcano's summit. The data are recorded on paper helicorder records.

The autumn 1974 eruption sequence began with minor explosive activity from 2 to 21 September, followed by a period of repose. Explosive activity occurred again from 29 October to 19 November, 25 November to 16 December and 25 December to 6 January. Each of these three periods of explosive volcanism began 3-4 days after fortnightly neap tides, in close agreement with Johnston and Mauk's previous results from Mt Stromboli, Italy.

	Table 1	Pavlof volcano seismicity				
Period		Mean no. of events per 2 h	s.d.	No. of data points		
Non-eruptive		10.05	5.65	96		
Pre-eruptive		26.74	18.81	114		
Eruptive		20.24	13.58	178		
Post-eruptive		14.19	13.53	161		

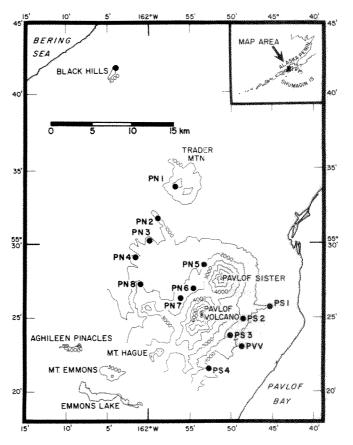

Fig. 1 Map showing stations of the Pavlof seismic array. Data are from station PVV, 7.5 km to the south-east of the volcano's

#### Seismicity

Data reduction consisted of detailed counts of each of four different types of volcanic earthquakes: high frequency tremors, harmonic tremor, explosion earthquakes and B-type earthquakes ranging in magnitude from -0.2 to 1.0 (Fig. 2) (S. McNutt in preparation). The numbers of events of each type per 2-h interval were plotted on histograms (see Fig. 3) for the entire time period from 1 September 1974 to 30 April 1975. Table 1 gives statistics for the general seismicity, broken down into four periods: non-eruptive (background), pre-eruptive, eruptive and post-eruptive. Seismicity is highest during pre-eruptive periods, followed by eruptive, post-eruptive, and background periods.

Table 2 Number of B-type events versus tidal stress rates in certain azimuths

A	Azimuth	0°	45°	90°	135°	Volumetric	N
Non-eruptive	14–16 January	0.17 $-0.21$	0.19 + 0.04	$0.19 \\ -0.46$	$0.14 \\ -0.22$	$0.20 \\ -0.26$	36
Eruptive	4-8 November	0.02 -0.04	0.11 +0.01	0.09 -0.26	0.00 0.00	0.05 $-0.11$	42
Pre-eruptive	29 October-1 November	0.45 -1.24	0.49 -1.67	0.49 -2.48	0.41 -1.45	0.51* -1.50	37
Post-eruptive	18-21 November	99% 0.22 +0.50	99% 0.22 +0.56	99% 0.33 +0.86	99% 0.31 +0.72	99,9% 0.29 +0.56	46
Pre-eruptive	22-26 November	0.25 -0.82	0.32 -1.25	98% 0.38 -2.16	95% 0.26 -1.05	95% 0.33 -1.10	43
Post-eruptive	7–12 January	0.35 +0.93 99%	95% 0.36 +1.09 99%	98% 0.34 +1.26 99%	0.32 +0.98 98%	95% 0.37* +0.93 99%	60

The upper value of each entry is the correlation coefficient, the second is the normalized slope and the third is the confidence level estimate for those cases where it is greater than 90%. N is the number of data pairs used.

\* The data plotted in Fig. 4.

Eruptive periods are so designated on the basis of the presence of explosive activity.

B-type earthquakes (Fig. 2) at Pavlof are nearly identical to those observed elsewhere  $^{7,10}$ . They have emergent onsets, no clear S-phases, dominant frequencies of  $\sim 1.4$  Hz, and coda durations of  $\sim 20$  s. Other studies in Japan have located B-type earthquakes at extremely shallow depths (1 km) immediately adjacent to active vents. The Gutenberg-Richter magnitude frequency relation for 1,316 B-type earthquakes which took place from 1 to 8 December has a negative slope or b-value of  $2.6 \pm 0.2$ , in close accord with values calculated for other volcanoes 1.0.1 Explosion earthquakes (Fig. 2) closely resemble B-type earthquakes, except for an impulsive spike  $\sim 21$  s after the signal onset. This spike is the air shock phase.

#### Tidal computations

The earthquake histograms were compared with a synthetic solid earth horizontal stress tide in azimuths 0°-180° and with volumetric stress. The components of the tide as a function of time and position were calculated by Longman's method 12, using a program which agrees closely with independent computations. Longman's method calculates tidal potential, from which stress is easily derived by differentiating and using the stress-strain relations with standard values of Love numbers and Lamé parameters. Visual inspection showed that earthquakes tended to occur at times of increasing or decreasing stress in certain azimuths. We therefore differentiated the synthetic stress tides with respect to time to generate stress rate tides (Fig. 3).

The ocean loading tide must be accounted for as well as the solid earth tide; for the particular case of Pavlof, the ocean load stress tide is approximately in phase with the solid earth tide. A rough calculation using Farrell's  $^{13}$  Green's functions and Schwiderski's  $^{14}$  ocean tide charts shows that for volumetric stress and for stress in azimuth N90° E the load tide maxima are within 1 h of the solid earth tide maxima. The load tide amplitude is  $\sim 30\%$  that of the solid earth tide; hence the inclusion of the load tide changes the phase by <1 h. We do not consider here the detailed effect of topography on the stress tide, but note that topography normally has a small effect on the phase  $^{15}$ .

#### Correlation data

Linear correlation coefficients between number of earthquakes per 2 h period and tidal stress rate for 15° increments in azimuth were calculated for portions of the eruption sequence. Figure 3 shows the number of earthquakes and two components of stress rate plotted against time for two pre-eruptive and two posteruptive portions of the data. The third post and pre-eruptive

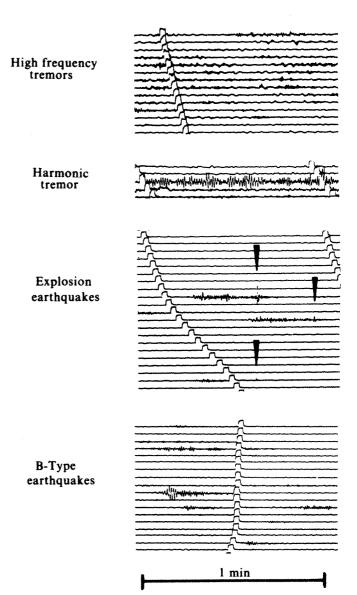

Fig. 2 Types of seismic signals recorded on helicorder from station PVV. Arrows point to air shock phase of explosion earth-quakes. Note the similar frequency content ( $\approx$ 1.4 Hz) of B-type earthquakes, harmonic tremor, and ground waves from the explosion earthquakes.

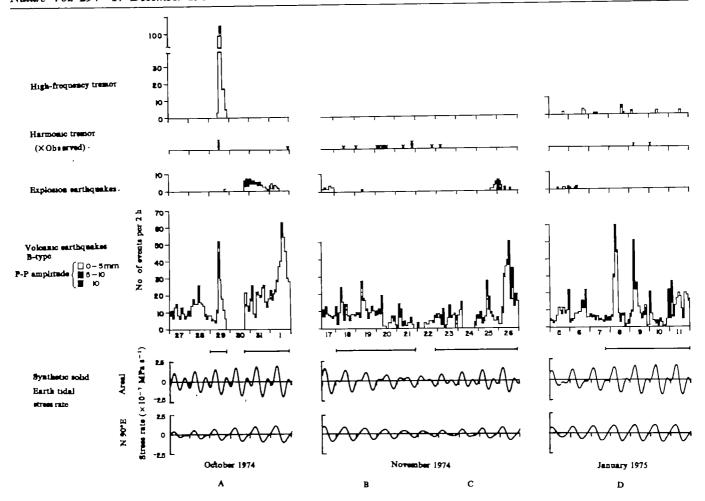

Fig. 3 Portions of histograms showing numbers of volcanic earthquakes of each type compared with synthetic solid earth tidal stress rate. A positive stress rate indicates increasing extensional stress. Note in particular the relation between the number of B-type earthquakes and tidal stress rate. A and C label pre-eruptive periods, while B and D label post-eruptive periods. During periods A and C peaks in the number of B-type earthquakes tend to occur at negative peaks in stress rate, while during periods B and D earthquakes occur at positive peaks in stress rate. See text for fuller explanation. The horizontal bars between the histograms and the tidal data show the portions of data actually used in the correlation calculations.

sequence is not shown; seismicity during this time period was the highest for the whole 7-month study period, and for reasons given below the results are less reliable. The results given in Table 2 show no statisticially significant correlation with tidal stress rate for either non-eruptive or eruptive seismicity. However, pre-eruptive and post-eruptive seismicity do show statistically significant correlations between the number of Btype volcanic earthquakes and the solid earth tidal stress rate for certain azimuths (Fig. 4). During pre-eruptive and post-eruptive periods earthquakes tend to occur at the times of tidal zerocrossings, that is when the rate of change of the tidal stress is most rapid. During pre-eruptive periods the correlation is negative: B-type earthquakes tend to occur at the time of most rapid increase in compressional tidal stress. For post-eruptive periods the correlation is positive: earthquakes tend to occur at the time of most rapid increase in extensional tidal stress. Table 2 shows a small but representative sample of the computed correlation data: estimates of correlation coefficients of regression, normalized slopes (that is, numbers of earthquakes per unit stress rate) and the confidence level of the correlation (the probability that the true correlation is greater than zero) are listed. We find that correlations with horizontal stress rate are better for azimuths from 75° to 105° than for other azimuths; correlations with volumetric (or areal) stress are similar to the best horizontal stress correlations.

#### Discussion

Ryall et al. 16 stated three criteria that should be met to evaluate optimally a tidal correlation: a statistically significant number of

events, a limited focal region, and a relatively constant character of accumulated strain in the region, as evidenced by focal mechanism study of the earthquakes. The first two conditions are met at Pavlof Volcano. Focal mechanisms could not be determined for the volcanic earthquakes because (1) it is nearly impossible for volcanic earthquakes to determine polarity of the emergent first arrivals, and (2) only one station was in existence at the time of this sequence of events; however, the signal characteristics are remarkably similar and are consistent with a relatively constant mechanism. Several other factors are important: the eruption was small, hence processes were smooth and slow rather than catastrophic; except for one time period (16-25 December) the seismicity was low enough that there was virtually no overlap problem in reading records; and the earthquakes themselves were small, thus the tidal stresses may have attained a larger fraction of the presumed stress drops (~a few bars) of the earthquakes than is the case for catastrophic events.

Our data are insufficient to determine unambiguously the focal process responsible for causing the earthquakes. Two processes are most likely; mode I (tensional) cracks and mode II (shear) cracks, which are both thought to occur as a result of magma injection into the volcanic pile. For the same crack geometry, however, the two processes would require different orientations of the principal stress axes to enhance most crack growth, or, vice versa, for a given stress system the two types of cracks most likely to be activated would be oriented at different azimuths. Our correlation data suggest a preferred orientation of cracks, but we cannot determine this orientation uniquely. Determinations of maximum horizontal compressive tectonic

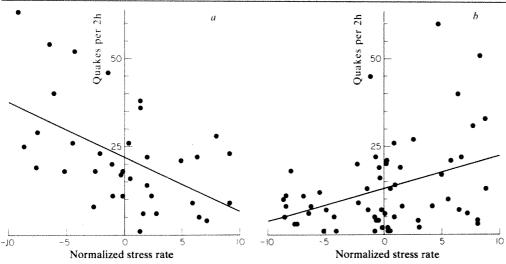

Fig. 4 Linear regression fits between earthquake frequency and stress rate. a, The data for a pre-eruptive period where the correlation is negative. The correlation coefficient is 0.51, and is >0 at the 99.9% confidence level. b, A post-eruptive period where the correlation is positive. The correlation coefficient is 0.37, and is >0 at the 99% confidence level.

stress<sup>17,18</sup> and the azimuth of relative plate convergence of the North American and Pacific plates 19 suggest an azimuth for the P-axis of maximum compression of approximately 150° which may control preferred crack growth in this direction if tensile cracks dominate, or at some angles ±45° from this azimuth if shear cracks dominate. This discussion does not consider pore pressure variations, which could change the effective stress significantly.

We tentatively interpret the change in sign of the correlation in terms of inflation and deflation of the volcano before and after eruptions, respectively. Some volcanoes tend to inflate before and deflate after eruptions<sup>7,20</sup>, presumably due to buoyant forces exerted by magma on the volcanic edifice as the magma migrates through dykes, but no geodetic data are available for Pavlof to confirm this hypothesis.

The tidal correlation applies only for a period of 3-4 days before and after explosive eruptions. As in previous studies<sup>2</sup> this implies that the volcano is sensitive to changes in ambient stress rate of  $\sim 2.5 \times 10^{-7}$  MPa s<sup>-1</sup> during the times when magma

is near the Earth's surface. Other volcanoes have quite slow rates of tectonic stress accumulation before eruptions<sup>20</sup>. The time period of 3-4 days may represent the time of magma ascent from or descent to a shallow magma chamber.

Our results indicate that the earth tide may have an effect on certain aspects of volcanic activity at Pavlof. This paper is believed to be the first to show a tidal correlation whose polarity with respect to tidal phase varies systematically during a volcanic eruption.

# Lithospheric studies based on holographic principles

P. Troitskiy, E. S. Husebye & A. Nikolaev

\* Academy of Science, Institute of Physics of the Earth, Moscow, USSR † NTNF/NORSAR, Post Box 51, N-2007 Kjeller, Norway

Earth holography was applied to Norwegian Seismic Array (NORSAR) earthquake P-wave recordings. Simulation of the NORSAR sensor configuration indicates that a satisfactory reconstruction of the essential features of an embedded body is feasible with a depth resolution which seems to be better than that attained using more traditional time and amplitude inversion schemes. The earth holography concept was tested using NORSAR recordings of three deep earthquakes at teleseismic distances. The results indicate lithospheric heterogeneous bodies with a significant vertical extent. The most pronounced scattering features of these inhomogeneities are located at depths around 100, 148 and 212 km.

DETAILED mapping of subsurface geological structures is important both for exploration for natural resources and for a better understanding of tectonic processes. The best tools are those tied to seismic wave analysis in view of the very short wavelengths involved compared with other geophysical investigations. During the 1970s two novel approaches were introduced: (1) the scattering approach using the concept of an isotropic random medium with a prescribed statistical velocity perturbation, correlation distance and turbidity factor<sup>1-3</sup>; and (2) the ACH method<sup>4-8</sup> which inverts travel time observations of a deterministic model into velocity perturbations. These approaches proved successful both in terms of three-dimensional seismic images of subsurface structures and in explaining precursor wavetrains<sup>9</sup> in the seismogram. A viable alternative might be to introduce a deterministic scattering model, assuming the presence of discrete inhomogeneities.

The surface wavefield manifestations of such inhomogeneities are in terms of diffraction effects which leads to an inverse diffraction problem for their mapping. This is analogous to the image reconstruction problems of holography<sup>10,11</sup>.

In applying holographic principles to analysis of seismological observations (earth holography), direct travelling seismic waves should be used because inhomogeneities often cause strong forward scattering. For example, Fig. 1 shows what the image of different structures should be when 'seen' by passing seismic waves. Compared with optic and acoustic holography, earth holography poses practical problems: complicated structure, the scale of the heterogeneities relative to that of useful seismic wavelengths is small, aperture of the sensor array is only of the order of 10–20 times the seismic wavelength as compared with a factor of  $10^7$  in optics, relatively poor wavefield sampling and background noise.

We now describe an attempt towards applying the principles of holography on a seismological scale. To test thoroughly the impact of the limiting factors an ultrasonic modelling experiment was undertaken to simulate the sampling of the NORSAR array in Norway<sup>12</sup> comprising 132 short period vertical seismometers (up to 1976).

#### Theoretical background

Despite extensive applications of the principle of wavefield reconstruction, its mathematical foundation has been formulated only recently 11,13-15 and the wavefield reconstruction has been reduced to a boundary value problem associated with the scalar wave equation.

The solutions of the forward and inverse diffraction may be written in similar forms using appropriate Green's functions:

$$U(x_2, y_2, z_2) = \frac{1}{2\pi} \int_{-\infty}^{\infty} U(x_1, y_1, z_1) \frac{\partial}{\partial z_1}$$

$$\times \left(\frac{\exp[-jkr]}{r}\right) dx_1 dy_1 \tag{1}$$

$$U(x_1, y_1, z_1) = -\frac{1}{2\pi} \int_{-\infty}^{\infty} U(x_2, y_2, z_2) \frac{\partial}{\partial z_2}$$

$$\times \left(\frac{\exp[jkr]}{r}\right) dx_2 dy_z \tag{2}$$

where for the forward problem the distribution of U (pressure or velocity fields) at plane  $z_2$  results from the knowledge of the distribution in the  $z_1$  plane  $U = U_1(x_1, y_1, z_1)$ , with  $z_2 > z_1 > 0$ . In the inverse problem the distribution of the wavefield in plane  $z_1$  is determined from knowledge of the field distribution on plane  $z_2$  (equation (2)). k is the wavenumber of the U-field and r is the distance between points in planes  $z_1$  and  $z_2$ .

A possible computational procedure for solving equation (2) follows from the convolutional nature of this equation, and is based on the FFT algorithm. Another technique which is adopted here is to take the derivative under the integral of equation (2) and assuming  $k \gg 1/r$  we then get:

$$U(x_1, y_1, z_1) = -\frac{j}{\lambda} \int_{-\infty}^{\infty} U(x_2, y_2, z_2) \frac{\exp[jkr]}{r}$$

$$\times \cos \theta \, dx_2 \, dy_2$$
(3)

where  $\theta$  is the angle of incidence. The approximation of equation (3) in combination with equations (1) and (2) is reasonable for the present models.

Further simplifications are feasible by a series expansion of r in the exponent of equation (3) and by retaining only the first two terms. This would be analogous to the Fresnel approximation used for solving forward diffraction problems.

#### Ultrasonic modelling experiment

The set-up of the ultrasonic modelling experiment is outlined in Fig. 2a, where the 'transparent' or homogeneous body is a parallelepiped made from epoxy with an embedded aluminium cross serving as the inhomogeneity whose image is sought reconstructed by holography. A monochromatic wave frequency of 880 kHz was used which is equivalent to  $\sim 1.8 \text{ Hz}$  in the seismological case. The choice of the frequency 1.8 Hz was motivated from the modelling experiment itself, implying an upper limit of  $1.3 \lambda$  for grid spacing. This is equivalent to  $\sim 4 \text{ km}$  in the seismological case (using a mantle velocity of  $8.2 \text{ km s}^{-1}$ ) which in turn reflects the NORSAR subarray sensor interspacing of 2-4 km. The major modelling parameters are also

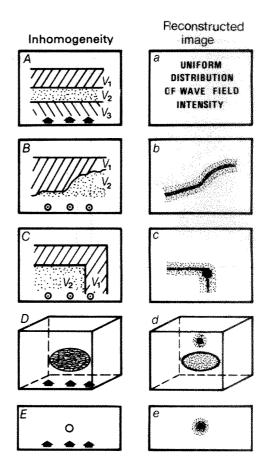

Fig. 1 Realistic earth inhomogeneities and their anticipated reconstructed holographic images. For A, D, E the illuminating plane-wave source is beneath the inhomogeneity while for B, C the source is located perpendicular to the plane of the figure. In A/a the reconstructed image would have uniform intensity so the inhomogeneity would appear transparent, thus contrasting sharply with conventional profiling results. For D/d the ghost image at intermediate depth reflects the smaller wave velocity of the object. The small single scatter object in E/e would probably be lost in a profiling survey.

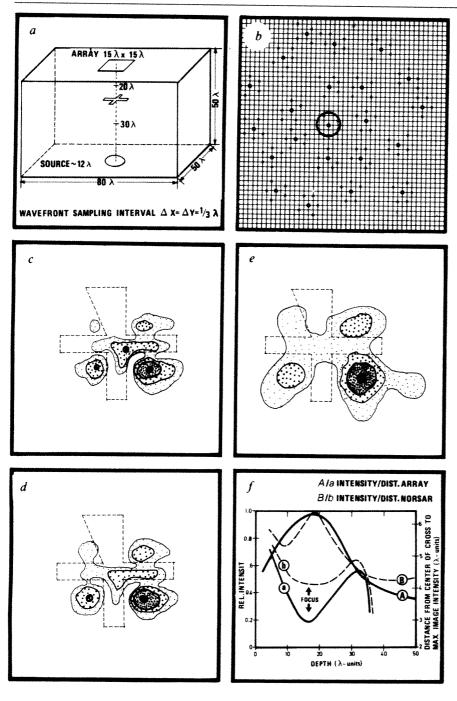

Fig. 2 Ultrasonic experimental set-up and results. a, The 'transparent' medium in the form of an epoxy box  $(v_p = 2.6 \text{ km s}^{-1})$  and the embedded inhomogeneity in the form of an aluminium cross ( $v_p = 5.2 \text{ km s}^{-1}$ ). The size of the box is  $80 \times 50 \times 50 \lambda^3$  while the standard length and width of the individual arms in the cross are  $\sim 12\lambda$  and  $\sim 2\lambda$  respectively. b, The two sensor configurations used: (i) a rectangular grid with 2,025 sensors with an interspacing of  $\lambda/3$  and (ii) a 132-sensor geometry similar to that of the NORSAR array. c, Image reconstruction of the cross (outlined) at its correct depth location on the basis of the regular grid network with contributions from all, 2,025 sensors to each reconstructed point. Relative intensity scaling is used with contour levels at 1, 2, 4 and 8 dB. d as c except that contributions are restricted to those observational points being within a radius equal to the diameter of the first Fresnel zone. The relatively high intensities observed at the centre of the cross in c and d stem from the non-plane source illumination. e, Image reconstruction of the cross when the observational points were limited to a simulated NORSAR array configuration of 132 sensors which in turn were extrapolated over a grid of  $25 \times 25$  points with 0.6  $\lambda$  interspacing. As in d contributions to each reconstructed point were limited to a radius equal to the diameter of the first Fresnel zone. f, Relative intensity as a function of image reconstruction depth for both configurations of b. The strongest intensity is found at the proper depth location of the cross and this coincides with a minimum distance from centre of the reconstruction axis. The intensity estimations for depth exceeding  $\sim 30\lambda$  reflects reconstruction of the source itself. The intensity maximum at the depth of the cross and the coinciding centre axis minimum distance both imply that depth resolution should be substantially better than that of three-dimensional time inversion<sup>4.5</sup>.

indicated in Fig. 2a; the epoxy block dimensions would correspond to an upper mantle block of roughly  $300 \times 300 \times 500 \text{ km}^3$ . Wavefront amplitude a(x, y) and phase  $\phi(x, y)$  were recorded across the sensor aperture area in 2,025 sampling points. By recording phase information, the reference wavefield required in optics is superfluous. Also, using computerized image reconstructions the three-dimensional 'view' typical of optic holography is substituted by two-dimensional cross-sections at different levels. This experiment is also considered adequate for simulating the NORSAR sensor configuration (Fig. 2b).

The cross-image reconstruction results are displayed in Fig. 2c-e for the two sensor configurations shown in Fig. 2b, namely, the whole grid of 2,025 sensors (Fig. 2c, d) and that of simulating the 132 sensor positions of the NORSAR array (Fig. 2e). The cross-images in the upper left quadrants of Fig. 2c-e are not entirely satisfactory and this prompted a reexamination of the experimental design. It was discovered that the source-positioning was slightly out of focus (lower right quadrant) and the source radiation was not plane but of a complicated spherical form. Taking these deficiencies into account, enables the pecu-

liarities in Fig. 2c-e to be explained rationally. For example, the strongest intensity is found in the lower right quadrant reflecting the asymmetric positioning of the source itself. The non-plane source radiation effect gave rise to focusing effects in the range  $16-23 \lambda$  below the array surface. This explains why the outer cross corners are not seen, and the existence of the centrally located intensity peak in Fig. 2c.

The results in Fig. 2c-e indicate that even in the case of gross holographic undersampling of the wave field, in particular for the simulated NORSAR configuration of 132 sensors only, a satisfactory reconstruction of the essential features of an embedded body seems feasible.

Another important aspect of the earth holography is that compared with other methods its depth resolution is probably very good. From optics the depth resolution would be  $2\lambda$  and  $1\lambda$  vertically and laterally for ideal cases. In the ultrasonic experiment the vertical depth resolution appears to be within  $3\lambda$  (Fig. 3f) which is highly satisfactory. In practical earth holography the depth resolution is likely to be less impressive, say, within  $5\lambda$  due to the relative complexities of lithospheric materials, but would still compare favourably with that obtained through

travel-amplitude inversion experiments. Other factors affecting the resolution in a rather complex way are array aperture, sensor spacing and depths to the anomalous bodies<sup>16</sup>.

#### Lithospheric heterogeneities

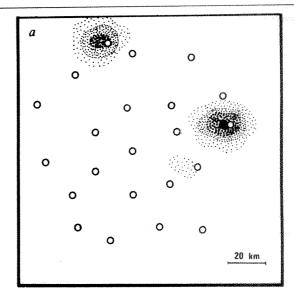

For testing the earth holography concept, NORSAR P-wave recordings of three deep earthquakes at teleseismic distances (South of Honshu, Hindu Kush and Western Brazil) were analysed. A characteristic feature of these recordings is that each of the 132 seismograms for one event exhibit an interference pattern of pulse-shaped waves propagating through the receiver region at slightly different paths. The first arrival is the direct (refracted) wave while scattering contributions arrive a little later. Obviously, the main information on lithospheric heterogeneities is confined to the initial part of the seismogram—here set to the first 10 s. The information extraction was tied to (spectral) amplitudes and phases for several harmonic components (0.6-2.6 Hz) of the recorded signals. However, as the 1.8-Hz component proved to be best, the results are restricted to this frequency. Note that the monochromatic signals of optical holography can be simulated by using a wideband frequency (or pulse) source in combination with sensors having resonant characteristics. The latter design is obtainable using digital filtering in time or frequency domain. Also, for image reconstruction the Earth's crust was given a thickness of 36 km and an average P-velocity of 6.5 km s while the lower part of the lithosphere was a half space with a P-velocity of 8.2 km s<sup>-1</sup>. Because this analysis is extremely computer-time consuming and each additional event only provides an independent set of reconstructed images the analysis was restricted to three clear event recordings.

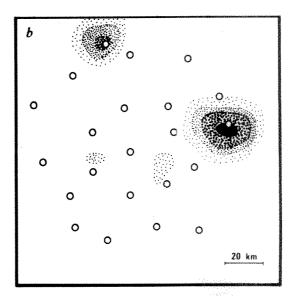

Results tied to image reconstruction of lithospheric heterogeneities under NORSAR using the south of Honshu earth-quake recordings are given in Fig. 3, which shows only the most striking features. At a depth of 100 km (Fig. 3d) the prominent intensity maximum to the east was the most concentrated one found over 14 intervals in the depth range 0-250 km. This bright spot also has the closest location relative to the centre of the array (see Fig. 2 legend).

For the anomaly to the north a similar effect is attained at a depth of 148 km (Fig. 3b). As depth increases the two anomalies deteriorate while two weak anomalies near the centre of the array emerge (Fig. 3c). Composite results for all three events analysed are shown in Fig. 4 for the same depth intervals as used previously. Area I is a rather weak anomaly at a depth of 148 km which is not clearly 'seen' by the western Brazil event; area II is the brightest heterogeneity of shallow depth (~100 km) which gives energy maxima for all three events; area III-a rather strong inhomogeneity—is located near the centre of the array, and is most clearly seen in the western Brazil results. The three events indicate different depth locations for areas I, II and III (III being the deepest), and that suggests a significant vertical extent of the heterogeneous bodies. These are 'illuminated' differently by the respective events, for example, side scattering by a rather strong heterogeneity seems to be required for anomaly II to be seen by the Western Brazil event. For areas IV. V and VI the anomalies are rather weak and are seen most clearly by the Western Brazil event.

#### Discussion

Much research effort has been devoted to analysing the complex P-wave field observed across NORSAR, and both random medium and derministic<sup>4,5</sup> approaches have been utilized. The latter result, the essence of which is indicated in Fig. 4 in terms of relative P-velocity anomaly contours, is the most comprehensive obtained so far and is a natural choice for a comparison with the outcome of the holography experiment, although a one-to-one overlap between the inversion results cannot be expected; time inversion has relatively poor depth resolution whereas earth holography results depend partly on the direction of the wave approach. Nevertheless, the relatively marked image intensities of areas II and III coincide reasonably well with the strong

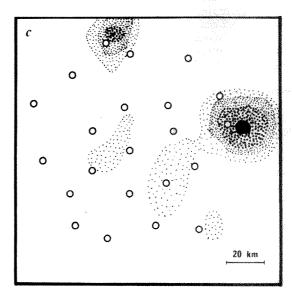

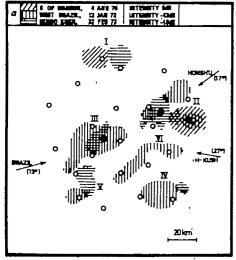

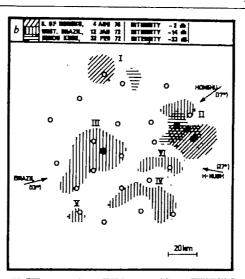

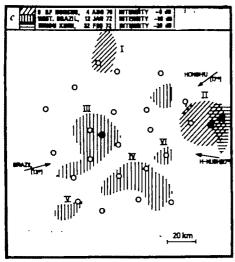

Fig. 3 Image reconstructions at depths of: a, 100 km, maximum intensity = 0 dB; b, 148 km, maximum intensity = -1.8 dB; and c, 212 km maximum intensity = -7.5 dB for the south of Honshu event using the computational procedure as indicated in Fig. 2e legend, frequency = 1.8 Hz. The intensity grading in each figure is in steps of 1 (black), 2, 4 and 8 dB down from maximum. The strongest intensity is to the east in a and is also the most concentrated. Note that this intensity has the closest location vis-a-vis the array centre and in this respect is similar to the focusing effect in Fig. 2f.

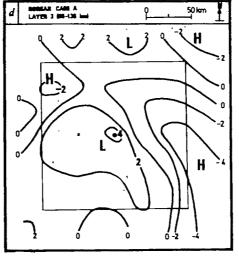

Fig. 4 Composite display of intensity maxima for depths. a, 100 km; b, 148 km; and c, 212 km exhibiting the most pronounced scattering features. frequency = 1.8 Hz. Different shading is used to identify the three events and their relative intensity scaling is also given. The contours of the various shaded areas are 4 dB down from the individual event maxima. A good overlap in a between the intensity areas for the different events implies that heterogeneities at this depth are most uniformly seen by the three events. b, Which has weaker intensities than a, also exhibits less of an overlap between the respective event intensity areas. Similar comments apply to a. The consistency in location of the intensity areas L II and III between a, b and c implies a significant depth extent of the heterogeneous bodies. For comparison the P-residual inversion results' in terms of relative velocity perturbations in per cent for model A of ref. 5, depth interval 85-135 km are displayed in d. There is reasonable agreement between these two types of seismic results. Note that the time inversion results for the depth interval 185-235 km are essentially the same as those for the 85-135 km interval, implying decreasing resolution with increasing depth with this method.

velocity anomalies obtained by direct inversion of travel time residuals. The intermediate image intensity of area I does not have a clear counterpart in the residual inversion results, and the same applies to the weaker area VI. In both these cases pronounced velocity changes occur nearby. The weak area V, may actually belong to area III as both are within the pronounced velocity low in the southwestern quadrant. The area IV inhomogeneity which is also weak may be associated like area II with the velocity high to the east. Area VI which is seen only by the Western Brazil event may be very deeply located (say > 200 km) and by that poorly resolved in view of the array's aperture of only 100 km.

We now consider the results of Fig. 4 in terms of geological structures. The fact that none of the anomalous areas observed seem to originate at shallow depth (≤80 km) is not unexpected as, with NORSAR's rather coarse sampling, the crust would appear relatively transparent. Thus, no obvious correlation was found with surface geological features such as the Oslo graben nor with a mylonite to the south-east. Except for the seismic manifestation of the Oslo graben<sup>5</sup> weak impedance contrast this agrees well with time residual inversion results. The anomalous body corresponding to the imagery reconstructions of areas I, II and III seems to represent bodies of different impedance contrasts and also different vertical extent. However, from the implied vertical extent of the heterogeneities corresponding to areas I. II and III we conclude that predominantly vertical processes take place within the lithosphere 17 and in particular in association with taphrogenesis18.

The interpretation of the results displayed in Figs 3 and 4 depends on the depth resolution of the associated anomalous areas which was discussed above with basis in optics. In earth holography the conditions are more difficult with noise in the

observations, the probable vertical extent of the anomalies and the general complexities of lithospheric structure. However, our previous estimate of  $5\lambda$  in the vertical direction seems to be confirmed by the intensity depth sharpness of the anomalous areas I, II and III and in this respect is substantially better than that obtained in the inversion experiments. For example, the Fig. 4f time inversion anomalies for the depth interval 85-135 km remain essentially unchanged when projected 100 km lower down<sup>5</sup>. The same applies to amplitude inversion experiments7.

#### Conclusions

We have demonstrated that acoustical holography can be applied to seismological observations from a large aperture array such as NORSAR. The results obtained in terms of located heterogeneous bodies in the lithosphere are in reasonable agreement with inversion results based on time residual observations from 183 events even though only three events were used for this analysis. Also, the depth resolution of our earth holography approach seems to be much better than that of the inversion technique and is estimated to be within  $5\lambda$  or 20 km in this particular case. The earth holography technique uses deterministic scattering effects often ignored in traditional seismic investigations and thus provides important, supplementary information on lithospheric heterogeneities.

The earth holography technique could be used on scales comparable with those used in seismic prospecting say for locating ore bodies, fault mapping and other sources of strong diffracted waves. However, the necessity of sufficiently dense sampling restricts its practical usage at present but its future application should be possible with improvements in digital

recording techniques.

We thank K. Aki for the idea of using NORSAR records for earth holography experiments, G. Fitzpatrick for guidance in adaptation of holographic methodology to seismology, and D.

# Base pairing of RNA I with its complementary sequence in the primer precursor inhibits ColE1 replication

R. M. Lacatena & G. Cesareni

European Molecular Biology Laboratory, Postfach 102209, 6900 Heidelberg, FRG

Four single base pair mutations in the region that codes for RNA I create new incompatibility groups while preserving the mechanism of control of initiation of DNA replication in a ColE1-type plasmid. Sequence analysis of these base substitutions points to the primary importance of the central loop of the cloverleaf structure of RNA I in this control mechanism.

PLASMIDS offer an attractive model for investigating the molecular mechanisms that ensure controlled replication of bacterial replicons during each division cycle. In many plasmids two species of RNA molecules, coded for in the region of the replication origin, seem to have a crucial role in the control of plasmid replication<sup>1-6</sup>. One of these, RNA II, is transcribed from a point upstream from, and towards, the replication origin, terminating at a point beyond it. In ColE1-like plasmids RNA II molecules have been shown in vitro to be processed at the origin of replication by RNase H (ref. 3) to form primers for the initiation of DNA synthesis by DNA polymerase I. The second, and smaller, RNA species, RNA I, is transcribed in the opposite direction to RNA II from the region of the plasmid genome shown genetically to determine plasmid copy number<sup>1,2,5</sup>. In vitro, RNA I molecules prevent the maturation of RNA II molecules, in a way that is not understood<sup>6</sup>. RNA I only inhibits primer formation by the plasmid that codes for it, having no effect on heterologous plasmids<sup>6</sup>, and it has been proposed that this interaction controls plasmid copy number. Here we show that single base pair substitutions in the region complementary to the central loop of RNA I's putative cloverleaf structure create new compatibility groups (defined by replication of the mutant in bacteria harbouring plasmids with homologous replication origins) by changing the specificity of the target of RNA I and suggest a model for the inhibitory interaction.

#### Isolation of target mutants

We expected that mutants altered in the target of the inhibitor of plasmid replication would be dominant high copy number mutants. However, rather than using direct selection for plasmids with a higher number of copies, we used an approach involving the phasmid system<sup>7</sup>, so as to avoid overlooking mutant plasmids potentially lethal for the host and to select against recessive mutants. This approach is particularly suitable for genetic analysis and relies on the possibility of incapsidating plasmid sequences in a  $\lambda$  phage head (Fig. 1).

We have previously observed<sup>7</sup> that the insertion of the plasmid pacl29 (Fig. 3) into the  $\lambda$  chromosome by int-mediated recombination confers on the hybrid the ability to grow on a homoimmune lysogen. This virulence is due to titration of  $\lambda$ 

repressor by the extra copies of  $\lambda$  operators that result from replication of the hybrid using the plasmid origin. The presence in the lysogenic strain of a resident plasmid that synthesizes the inhibitor of plasmid replication prevents virulence by blocking the initiation of plasmid DNA synthesis in the incoming phasmid. A phasmid with an altered inhibitor target will be able to escape repression and will be virulent even in the presence of a resident plasmid (Fig. 1a).

The isolation of such inhibition-insensitive mutants (svir) will be described in detail elsewhere<sup>8</sup>; here we summarize their properties. Six independent svir mutants were isolated. Only four of them can be released efficiently from the  $\lambda$  chromosome by infection of an int constitutive strain (Fig. 1b); the remaining two mutants, svir3 and svir19, are lethal for the host and cannot be propagated as plasmids. Three of the mutant plasmids that replicate efficiently show an increase in relative copy number with respect to wild type (Table 1). This increase is dominant in a complementation test. Unexpectedly, the remaining mutant, svir11, is present in the host bacterium with a lower number of copies than the wild type (0.7 relative copy number), as if the mutation had created a better mechanism of self repression. From the behaviour of these mutants in compatibility experiments we conclude that the target of the inhibitor of ColE1-type replication coincides with part of the inhibitor coding sequence. As a consequence, single mutations in the target result in altered inhibitors that are unable to interact with the wild-type target. This hypothesis is consistent with what is known about the transcriptional organization of the replication region of ColE1 and the finding that RNA I inhibits primer formation by acting somewhere further upstream than 300 nucleotides from the

#### Specificity test

If svir plasmids are mutated not only in the target but also in the repressor, we are left with the puzzle of the low copy number of svir11. One possible explanation would be that a single base pair change had modified target and repressor in a complementary way that maintained and possibly improved the interaction between the two mutated elements. To test this hypothesis we devised the test shown in Fig. 2 where each svir phasmid

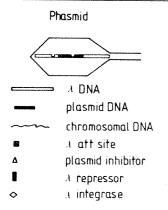

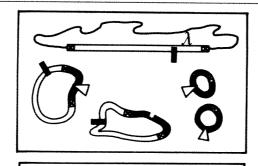

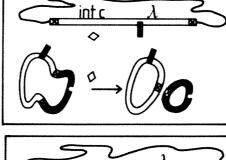

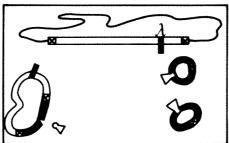

Fig. 1 The phasmid system. The drawings illustrate schematically how a phasmid can be used to select dominant mutants in the target of the negative regulator of plasmid replication. The phasmid<sup>7</sup> is a hybrid obtained by in vivo integration into the  $\lambda$  chromosome of a plasmid containing an att site. The resulting hybrid molecule can be encapsulated into  $\lambda$  heads and, as a consequence, plasmid sequences can be injected into different bacterial environments by phage infection. Infection of a lysogen containing a plasmid of the same compatibility group (a) will not lead to any phage production. Both phage and plasmid replication system are, in fact, blocked. Phasmid mutants carrying an altered target for the inhibitor of plasmid replication can replicate under plasmid control and start a lytic cycle when the copy number reaches a value sufficient to titrate-repressor. The process of plasmid integration is reversible and plasmid sequences can be excised from the  $\lambda$ chromosome (b) by infecting the strain EQ84 =

a Supervirulence test.
Only phasmid with altered target for plasmid inhibitor will be able to replicate efficiently

b Release of plasmid Excision of plasmid sequences in integrase constitutive strain

c Specificity test.Do mutant plasmid repressors crossreact with mutant targets?

HfrH galT  $\Delta$ (int-FII) ( $\lambda$  inte 226) that constitutively synthesizes  $\lambda$  integrase. Clones that contain the original plasmid sequences can be selected at 30 °C on plates containing 50  $\mu$ g mI<sup>-1</sup> of ampicillin. The experimental details of the specificity test (c) are described in Fig. 2 legend.

(horizontal lines) was spotted on a lawn containing a permissive indicator together with a lysogenic strain harbouring the different *svir* plasmids (vertical lines). A turbid spot indicates that the phasmid is unable to replicate in the corresponding lysogenic strain. Insensitivity to the inhibitor synthesized by the resident plasmid will result in phasmid replication, virulence and, as a consequence, in a clear spot. Experiments of the type shown in Fig. 2 clearly indicate that not only *svir11*, but also the three high copy number *svir* mutants, can still synthesize an active inhibitor. Furthermore, the turbid spots are present only in the diagonal, indicating that the mutant inhibitors are active only on their own target and not on the targets of the wild-type plasmid or of the remaining mutants. The only exceptions are *svir2* and *svir7*, which seem to have the same specificity. Our sequence data identify them as identical.

We conclude from these experiments that a mutation in the target of this repression system causes a complementary alteration of the inhibitor itself so that the control mechanism remains functional despite the change in specificity. These properties are consistent with a repression mechanism based on base pairing between complementary nucleic acid.

#### svir mutants define new compatibility groups

The 'inhibitor dilution' model<sup>9</sup> proposes that incompatibility is the result of the inhibitory activity of a negative regulator of plasmid replication that is unable to distinguish between two homologous replicons. Given the results of the specificity test in Fig. 2, this model predicts that each *svir* mutant should be compatible with all the others but incompatible with itself. To test this prediction we constructed (Fig. 3) tetracycline-resistant derivatives of the wild-type plasmid and of the three mutants with different specificities (*svir7*, *svir11*, *svir12*). Heterozygous cells containing all the possible combinations of ampicillin- and tetracycline-resistant derivatives were constructed by co-transformation of the *recA* strain HB101. The percentage of clones

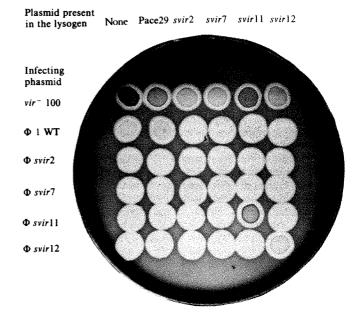

Fig. 2 Specificity test. The plate was prepared by overlaying a BBL plate (Baltimore Biological Laboratories; trypticase  $10 \, \mathrm{g} \, \Gamma^{-1}$ ) with 3 ml of top agar (as BBL agar but only 6.5 g agar per 1) containing 0.2 ml of a saturated culture of GC57 =  $\Delta(lac-pro)malA$  metal arg  $E_{am}$  rif thi supf. This strain is used as a permissive strain for all the phasmids tested. 0.3 ml of a dilution of phasmid lysates containing  $\sim 10^7$  plaque-forming units per ml was added to the wells of the horizontal lines of a microtitre plate. The wells in the vertical lines of the resulting grid were further inoculated with 0.05 ml of the lysogenic strain Q37 (thr leu lacY supE ( $\lambda P_{am3}$ )) containing the plasmid pacl29 or one of its svir derivatives. 5  $\mu$ l of the content of each well were spotted in a corresponding grid on the plate containing GC57. The photograph was taken after 24 h incubation at 37 °C. vir100 is a replication-defective derivative of the phasmid  $\Phi$ 1 (ref. 8). WT, wild type.

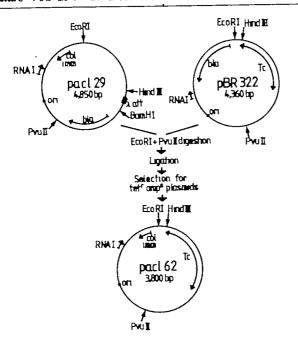

Fig. 3 Incompatibility properties of sour derivatives. Tetracycline-resistant derivatives of the plasmid paci29 and of the three sour mutants with different specificities, were constructed using the strategy shown. DNA from the plasmid pBR322<sup>14</sup> and paci29 was digested with the restriction endonucleases EcoRI and PosII. Equimolar amounts of the two digested DNAs were mixed at a concentration of 10 µg mi<sup>-1</sup> and ligated overnight at 14 °C. After transformation of a culture of HB101 made competent by CaCl<sub>2</sub> treatment, the transformed clones were selected on tetracycline plates (10 µg mi<sup>-1</sup>). The desired paci62 structure can be recognized from reconstituted pBR322 by replica plating on ampiculih plates (100 µg mi<sup>-1</sup>) sou? and source pacific derivatives have lost the PosII site in this construction probably because of some exonuclease activity in the enzyme preparation

that had lost either of the two plasmids after growth in non-selective medium was monitored approximately every 20 generations by plating in the presence of antibiotics. Table 1 shows the number of generations required to decrease by one order of magnitude  $(D_{-1})$  the number of clones containing both plasmids. As predicted by the inhibitor dilution model, only combinations that have cross-reacting inhibitors result in rapid segregation of clones containing only one of the two plasmids. After 150 generations, less than 1 out of 200 clones had lost one of the two plasmids in the segregation experiments on either side of the diagonal of Table 1.

These compatibility experiments support the hypothesis raised in the previous section and prove that, as predicted by the inhibitor dilution model, an alteration of the specificity of the inhibitor—target interaction results in altered compatibility properties. Given the peculiar repression system devised by ColE1-type replicons, it is possible to create new compatibility

Table 1  $D_{-1}$  values in segregation experiments

 $D_{-1}$  values are given for the segregation experiment of bacterial strains containing the various combinations of ampicillin- and tetracycline-resistant derivatives. Clones containing two plasmids were constructed by co-transformation and selection on plates containing both antibiotics. One doubly resistant clone for each transformation was plated on an L plate and one colony still resistant to both antibiotics was grown for several generations (with dilutions in the plateau phase) in non-selective conditions. Every 20 generations the cultures were intrated and one plate containing ~200 colomes was replica-plated on to ampicillin and tetracycline plates. The number of generations required to decrease by a factor of 10 the percentage of cells containing both plasmids  $(D_{-1}$  values) were obtained from such segregation curves. The values in the diagonal are the average of three independent determinations. The first column shows the relative copy numbers of some mutantial.

groups by single base pair changes. Our results are not consistent with models of the type proposed by Bedbrook *et al.*<sup>10</sup> that stress the importance of membrane replication–segregation sites in determining plasmid incompatibilty.

The  $D_{-1}$  values of the different *svir* mutants were not proportional to plasmid copy number. We cannot explain this result, which seems to conflict with models based on random replication and random segragation<sup>11,12</sup>.

#### Location of svir mutants

The four base pair changes that cause the change in specificity of the control mechanism have been previously localized by in vivo deletion mapping between nucleotides 295 and 511 upstream from the origin of plasmid replication. This DNA fragment was sequenced by the chemical degradation method and revealed in each case a single base pair transition in the region that codes for RNA I. Figure 4 shows the base changes

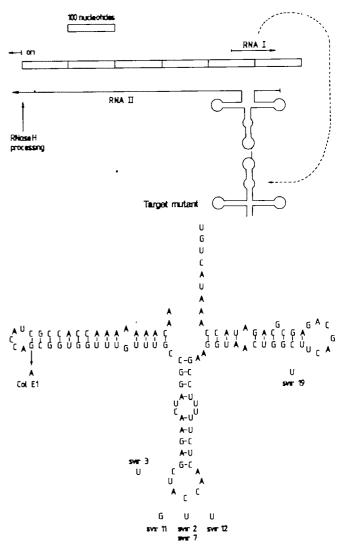

Fig. 4 Model of the ministory interaction between RNA I and the primer precursor and DNA sequence of the mutants. The DNA sequence of the wild-type pard29 (no difference from the published pBR322 sequence <sup>13</sup>) and of the sour mutants was obtained using the chemical degradation method <sup>13</sup> end labelling with DNA polymerase (Klenow subunit). The wild type and the two mutants obtained with nitroeoguanidine mutagenesis (rol2, sou7) were sequenced from the PoulI site ~500 nucleotides downstream from the origin of replication up to the end of RNA I in order to be able to exclude the possibility of secondary mutations, sou?11 and sou?12 (obtained by mutD mutagenesis) were sequenced only in the HpaII fragment that was shown by deletion mapping to contain the mutation, sou?3 and sou?19 cannot be propagated in the plasmid form. The Sau3A-TaqI DNA fragment that was used for sequencing was therefore prepared from phasmid DNA. The arrow in the right loop of the RNA I synthesized by the related plasmid CoIE1 The row mutations are shown as alterations of the RNA sequence of the primer precursor.

with respect to the wild-type sequence. The three base transitions at positions 55, 56 and 57 of the RNA I sequence indicate the importance of this triplet in the nucleic acid-nucleic acid interaction controlling pMB1 replication. The number of mutations isolated and sequenced is insufficient to define the limits of the site of interaction between repressor and target. Nevertheless, the clustering of the four mutations at the top of the central loop of the cloverleaf structure of RNA I is reminiscent of a 'codon-anticodon type' interaction between transfer RNA and messenger RNA. We do not know whether this observation has any functional or evolutionary significance.

# Target mutants that alter the cloverleaf

The two remaining inhibitor-insensitive mutants, svir3 and svir19, when released from the  $\lambda$  chromosome, are lethal for the host cell. We assume that this phenotype is due to uncontrolled replication. Strong selection for plasmid release and maintenance results in deletions of part of the mutant plasmid. The two mutations were localized by deletion mapping between nucleotides 295 and 511 from the origin of DNA replication. The corresponding DNA fragment was prepared from phasmid DNA and sequenced by the chemical degradation method. svir3 was found to be a base substitution that might affect target function by extending the central stem of the cloverleaf structure, thus preventing the anticodon-type base pairing with the inhibitor. The tRNA-like secondary structure is also disturbed by the  $C \rightarrow T$  transition in svir19 that affects the stability of one of its stems.

#### **Conclusions**

In four of the svir mutants that have been characterized, single base pair transitions resulted in a change of specificity in the mechanism of control of copy number without destroying its function. We believe this to be the first description of such a mechanism, which allows evolution while ensuring protection of function. It is possible that the relevance of this mechanism extends to biological phenomena in which self recognition plays

a role. A single mutation may allow for the evolution of a new class of specificity while preserving, through the complementary alteration of the target sequence, the mechanism of self recognition.

Our results point to the crucial function of the central loop of RNA I in the interaction that leads to inhibition of initiation of ColE1 replication. Conclusions about the bases involved in these interactions must await the isolation and characterization of more mutants of different specificities. The specificity test that we have devised (Fig. 2) offers an easy tool for this type of

It is interesting that the mutant copy number phenotype is correlated with the free energy content of the hydrogen bonds between the nucleotides of the two triplets postulated to be involved in the interaction.  $C \rightarrow U$  transitions respond to increase in copy number while the only  $A \rightarrow G$  transition results in a low copy number plasmid, probably as a consequence of the better repressor target interaction. The dramatic change in the efficiency and specificity of the control mechanism caused by single base substitutions suggests that this interaction does not involve a large number of bases.

From our results and the in vitro experiments of Tomizawa et al.6, we propose (Fig. 4) that the base pairing between the central loop of RNA I and the complementary structure on the nascent primer precursor is essential in preventing maturation of this latter transcript, probably by preventing the formation of the RNA-DNA hybrid that is the substrate for the maturation enzyme RNase H. Furthermore, we have evidence that the stability of the cloverleaf structure of the target is a requirement for successful inhibitory interaction. Two mutations that alter two of the stems in the target putative secondary structure result in insensitivity to wild-type inhibitor. Our results, however, do not allow us to distinguish whether RNA I interacts with the primer precursor or with its own DNA coding sequence. This will require further genetic and biochemical experiments.

# Two conserved sequence blocks within eukaryotic tRNA genes are major promoter elements

Gabriella Galli, Hans Hofstetter & Max L. Birnstiel

Institut für Molekularbiologie II der Universität Zürich, Hönggerberg, 8093 Zürich, Switzerland

The split promoter sequences of a tRNA<sub>CUG</sub> gene of Xenopus laevis have been mapped to nucleotides 13-20 and 51-64 of the tRNA Leu coding sequences. The sequences closely coincide with two conserved sequence blocks present in all eukaryotic tRNA genes. The two conserved sequence blocks were found to be exchangeable between tRNA genes as chimaeric tRNA det et RNA genes proved transcriptionally active. Furthermore, two prokaryotic tRNA genes exhibiting strong homologies with the two blocks yielded specific transcripts when tested in an eukaryotic transcriptional system.

THE tRNA Met genes of Xenopus laevis have an unusual splitpromoter arrangement in that sequences directing transcription are located near both the 5' and the 3' end of the tRNA Met gene unit1. As in the case of the 5S RNA gene2.3 of the same genus and the VAI gene of adenovirus4, the control regions of the tRNA<sup>Met</sup> are located within the structural gene itself (reviewed in ref. 5). Here, we show that a tRNA CUG gene of X. laevis has a similar split promoter and trace the essential sequences to two

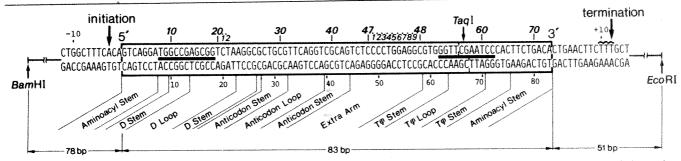

Fig. 1 DNA sequence of the tRNA Lew gene of X. laevis. The DNA sequence coding for the tRNA Lew is boxed. The numbers in bold-faced type above the box are in agreement with the standardized numbering system? Consecutive numbering is shown below the box. The bars between the two DNA strands show the location of the conserved elements which are discussed in detail in Fig. 4 legend.

sequence blocks which are highly conserved in all eukaryotic tRNAs. We present evidence that the promoter organization of genes transcribed by polymerase III can differ substantially and argue that the split promoter arrangement of the tRNA genes is in keeping with the evolution and functional diversity of the tRNA structure.

#### The tRNA<sup>Leu</sup> gene transcription unit

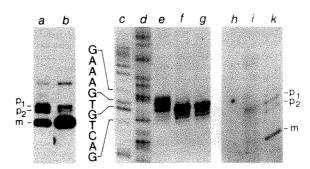

Figure 1 displays the DNA sequence of the X. laevis tRNA<sub>CUG</sub> gene<sup>6</sup> used in the present study, together with the DNA sequences of the adjacent flanking regions. The numbers in bold-faced type above the DNA sequence of the structural gene are in accord with the standard tRNA numbering system<sup>7</sup>, which is based on the primary structure of the yeast tRNA<sup>Phe</sup> and is used here throughout. The tDNA Leu fragment was isolated from a cloned 3.18-kilobase (kb) DNA repeat<sup>8</sup> by cleavage with Mbol and EcoRI and was then cloned between the EcoRI and BamHI sites of pBR322. On injection of the recombinant plasmid with  $[\alpha^{-32}P]$ GTP into the nuclei of frog (Xenopus laevis) oocytes<sup>9</sup> (for technical details see ref. 10) followed by a short incubation period of 3 h, three labelled RNAs (m, p<sub>1</sub> and p<sub>2</sub>) were detected by electrophoresis on denaturing polyacrylamide gels (Fig. 2, lanes a, b). Band m was previously identified by RNA sequencing as mature tRNA<sup>Leu</sup> (S. Clarkson and R. Koski, personal communication) containing 85 bases, including the common 3'-terminal CCA sequence which is added post-transcriptionally. The two larger RNAs p<sub>1</sub> and p<sub>2</sub> are 98 and 95 nucleotides long, respectively, and represent precursors to the mature tRNA<sup>Leu</sup>. The intensity of band m increased with longer incubation times whereas bands p<sub>1</sub> and p<sub>2</sub> were only faintly visible after overnight incubation.

The approximate position of the 5' termini of p<sub>1</sub> and p<sub>2</sub> on the tDNA was determined by S<sub>1</sub> mapping experiments<sup>5,11</sup> using individual, gel-purified p<sub>1</sub> and p<sub>2</sub> RNA and a complementary hybridization probe, 5'-end labelled at the TaqI site (see Fig. 1). After S<sub>1</sub> digestion of the hybrids, the products were fractionated on a denaturing polyacrylamide gel: p2 and m gave identical S<sub>1</sub>-protected DNA bands (Fig. 2, lanes f, g) and hence these molecules are presumed to have identical 5' termini; therefore, both molecules have a G as the first base in the sequence. The DNA fragments protected by  $p_1$  were two or three bases longer, hence the 5' end of  $p_1$  maps at the A or C at position -3 or -2. We next investigated whether both p<sub>1</sub> and p<sub>2</sub> could be primary transcripts. [\(\beta^{-32}\)P]GTP or -ATP were injected with the tRNALeu gene and RNA was isolated after a short 30-min incubation to avoid transfer of the label to the  $\alpha$  position<sup>5</sup>. Injection with  $[\beta^{-32}P]GTP$  did not result in labelling of any of the transcripts, whereas injection of  $[\beta^{-32}P]ATP$  labelled only the  $p_1$  transcript (Fig. 2i). We conclude that  $p_1$  is a primary transcript commencing with an A at position -3 and that p<sub>2</sub> and m are derived from p<sub>1</sub> by processing at the 5' end. Considering the length of p<sub>1</sub> and p<sub>2</sub>, it seems likely that the 3' end of both precursors maps to position +11 or +12, that is, to the two last bases of the putative termination signal TTCTTT in the 3'flanking sequence.

#### The intragenic promoter

Having established the size of the tRNA<sup>Leu</sup> transcription unit, we constructed deletion mutants lacking sequences at either the 5' or the 3' end of the tRNA<sup>Leu</sup> gene. The BamHI and EcoRI sites at positions -78 and +51, respectively, provided convenient starting points for resection with exonuclease Bal31. After the addition of HindIII linkers to the resected ends, the truncated tDNA<sup>Leu</sup> fragments were recloned, all in the same orientation, into the pBR322 vector, between either the EcoRI and HindIII or the BamHI and HindIII sites. The extent of the sequence truncation was determined by DNA sequencing<sup>12</sup> and its effects on transcription finally assessed by oocyte injection. To normalize the amount of transcription in each injection experiment, cloned 5S DNA of X. laevis<sup>13</sup> was routinely coinjected as an internal control at a level of one 5S RNA gene per four tRNA<sup>Leu</sup> genes.

The resected clone a (Fig. 3), which lacks most of the 5'-flanking region but still contains the precursor transcription unit, is transcribed at the same level as the progenitor clone. Further

Analysis of transcripts made from the tRNA wild-type gene. The small DNA fragment shown in Fig. 1 was isolated from a cloned 3.18-kb DNA repeat unit8 after cleavage with EcoRI and Sau3A and was then cloned with pBR322 between the EcoRI and the BamHI restriction sites. Plasmid DNA was isolated by the clear-lysate method<sup>22</sup> and further purified by isopropanol precipitation and centrifugation in a CsCl step gradient. After recovery and reprecipitation, the DNA used for oocyte injection was dissolved in 88 mM NaCl, 10 mM Tris HCl pH 7.4, at a concentration of 200  $\mu$ g ml<sup>-1</sup>. A 20 nl aliquot of this DNA solution containing  $0.2 \,\mu$ Ci of  $[\alpha^{-32}P]$ - or  $0.4 \,\mu$ Ci of  $[\beta^{-32}P]$ -triphosphates was injected into nuclei of centrifuged oocytes as described earlier<sup>9,10</sup>. The oocytes were incubated for 0.5-16 h and total nucleic acids then isolated. The labelled RNAs were analysed by electrophoresis through 10% polyacrylamide, 8 M urea sequencing gels and detected by exposure to X-ray film using an intensifier screen. For S<sub>1</sub> mapping, individual RNAs (m, p<sub>1</sub> and p<sub>2</sub>) were isolated from the gel<sup>12</sup> and the RNA from one oocyte was hybridized to the 5' half of a tDNA<sup>Leu</sup> fragment which had been 5'-end labelled at the *Taq*I site (compare Fig. 1). Hybridization was carried out in 20 µl of 80% formamide, 0.4 M NaCl, 40 mM MOPS pH 6.7, and 1 mM EDTA at 51 °C for 16-24 h. The reaction was stopped on ice with 180  $\mu$ l ice-cold S<sub>1</sub> buffer (30 mM NaAC pH 4.5, 2 mM ZnSO<sub>4</sub>, 0.2 M NaCl). 10 U of S<sub>1</sub> enzyme were added and the samples were incubated at 41 °C for 45 min. The analysis of the protected DNA fragments was carried out on a 10% polyacrylamide, 7 M urea sequencing gel. Lanes a, b, RNA isolated from two oocytes incubated for 3 (a) and 15 (b) h; lanes  $e, f, g, S_1$  mapping of  $p_1(e), p_2(f)$  and m(g); lanes c, d, A-specific (d) and G-specific (c) sequence reaction of the DNA probe used for  $S_1$  mapping; lanes h, i and k, labelling with  $[\beta^{-32}P]GTP$  (h) and  $[\beta^{-32}P]ATP$  (i) and  $[\alpha^{-32}P]GTP$  (k) for 0.5 h. RNAs extracted from 46 (h), 52 (i) and 1.5 (k) oocytes were loaded onto the gel. Exposure time was 48 h.

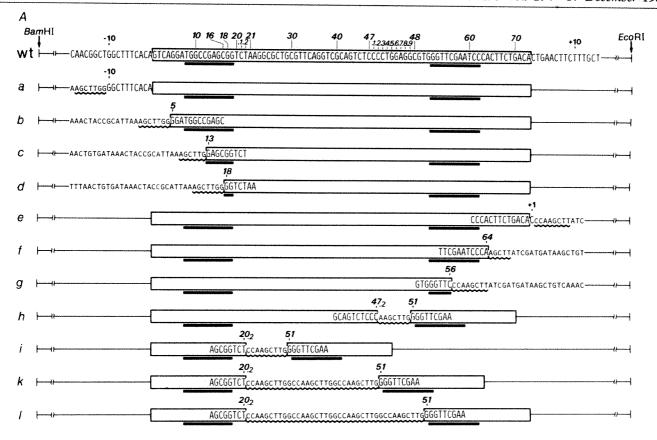

Fig. 3 Structure and transcription of the tDNA<sup>Leu</sup> mutants. The starting material for the resection of the tRNA<sup>Leu</sup> gene was the clone described in Fig. 2 legend. 15 µg of this plasmid were cleaved with EcoRI and another 15 µg with BamHI. The linearized DNA was treated for 30 min at 30 °C with 0.2 U Bal31 double-strand exonuclease<sup>23</sup> in 20 mM Tris pH 8.1, 600 mM NaCl, 12 mM MgCl<sub>2</sub>, 1 mM EDTA. In these conditions up to 200 nucleotides are resected from each end. 40 pmol of synthetic *HindIII* linker labelled with  $[\gamma^{-32}P]$ ATP were ligated to the *Bal31*-digested DNA, giving about a 15-fold molar excess of linker to DNA ends. Unreacted HindIII linkers were removed by centrifugation through a 5-20% sucrose gradient using a SW40 rotor. The plasmid DNA was precipitated and after resuspension in buffer digested with 80 U HindIII followed by BamHI or EcoRI. The DNA fragments were separated on a preparative 8% polyacrylamide gel and eight gel slices were cut out containing DNA fragments ranging from 50 to 200 bp. After elution from the gel and chromatography on DEAE-Sephadex, the DNA fragments were cloned with pBR322 which had been previously cleaved with EcoRI and HindIII or BamHI and HindIII and then treated with phosphatase24. Recombinant plasmids were identified by restriction analysis and DNA sequencing. To produce insertion and deletion mutants, the individually cloned small subfragments were prepared from the recombinant plasmids by digestion with EcoRI and HindIII or BamHI and HindIII followed by preparative polyacrylamide gel electrophoresis, elution from the gel and chromatography on DEAE-Sephadex. 1 pmol of pBR322

plasmid DNA which had been cleaved with EcoRI and BamHI and treated with alkaline phosphatase was ligated with 1 pmol each of two corresponding DNA fragments. A, structure of the different tDNA<sup>Leu</sup> mutants. The structural gene is boxed, X. laevis DNA sequences are shown in large letters, HindIII linkers and pBR322 sequences in small letters. HindIII linkers are underlined with wavy lines. Original sequences at the junctions which have been restored by the addition of HindIII linkers were considered as part of the gene unit. The bars below the sequence indicate the conserved sequence motifs. B, transcriptional analysis of the mutants carried out as described in Fig. 2 legend. Incubation time after injection was 3 h for wt and mutants a, e and h, and 15 h for mutants b, c, d, f, g, i, k and l. RNA from two oocytes was loaded on to the gel and the film was exposed overnight. Lane M, pBR322 plasmid DNA digested with HpaII and end labelled with  $[\gamma-^{32}P]ATP$ . The length in nucleotides of the single-stranded DNA fragments is given to the left.

resection up to and including nucleotide 4 of the structural gene (clone b) deletes the normal initiation site but permits continued synthesis of several precursor molecules, albeit at a slightly reduced rate.  $S_1$  mapping demonstrated that the majority of the transcripts from clone b initiate at the junction between plasmid and linker DNA and their heterogeneous length seems to stem from inefficient termination and incorrect processing (data not shown). The 5' border of essential promoter sequences can be placed around position 13, as clone c, which lacks 12 nucleotides of the structural gene, is still transcribed, although very poorly, whereas clone d, which lacks 16 nucleotides, is totally inactive.

Removal of the 3'-flanking sequences, including the putative termination signal TTCTTT(clone e), did not affect the rate of transcription but led to the synthesis of a 165-base precursor which, as deduced from its length, terminated within a run of Ts

located in the pBR322 plasmid DNA at positions 4,323–4,327 (ref. 14). A mutant which lacked 9 base pairs (bp) of the 3'-terminal sequences of the structural gene was transcribed at a reduced rate (clone f). However, a mutant lacking 17 bp was completely inactive (clone g). From the results of these two sets of experiments we conclude that the essential promoter sequences of the tRNA<sup>Leu</sup> gene, detectable by oocyte injection experiments, are located somewhere between positions 13 and 64 of the structural gene.

#### The split promoter of the tRNA Leu gene

To assess whether the gene-internal tDNA<sup>Leu</sup> promoter is discontinuous, as is the case for the tDNA<sup>Met</sup> promoter, we constructed mutants in which the central portion was replaced by a variable number of *HindIII* linkers. In one such tDNA<sup>Leu</sup>

mutant the 14-bp region coding primarily for the extra arm of the tRNA Law (standardized positions 47.3 and 50) was replaced by a 10-bp synthetic HindIII linker DNA segment. This mutant was transcribed almost as efficiently as the wild-type gene (Fig. 3, clone h). Another mutant in which the 16 bp at positions 21-37 were replaced by 30 bp provided by three concatenated HindIII linkers, yielding an expanded gene, resulted in about 40% of the normal level (data not shown). In a third mutant, a segment 40 nucleotides long (positions 21-50) was replaced by one, three or four HindIII DNA linkers. The mutant containing one *HindIII* linker proved inactive in transcription (clone i). Substitution of the deleted sequences by three HindIII linkers reactivated the gene unit to a very small extent (clone k). Four HindIII linkers, which together exactly replace the length of the deleted sequences (clone I), activated transcription to a moderate level (discussed below).

Our previous experiments with the tRNA<sup>Mot</sup> gene<sup>5</sup> showed that control sequences were located in the anterior and posterior portions of the structural gene. Considering the above substitution-deletion mutants of the tRNA<sup>Lon</sup> gene as well as those created by 5' and 3' resection, a picture emerges which is more differentiated than that provided by the previous tDNA mutants. All four boundaries of the two gene-internal promoter

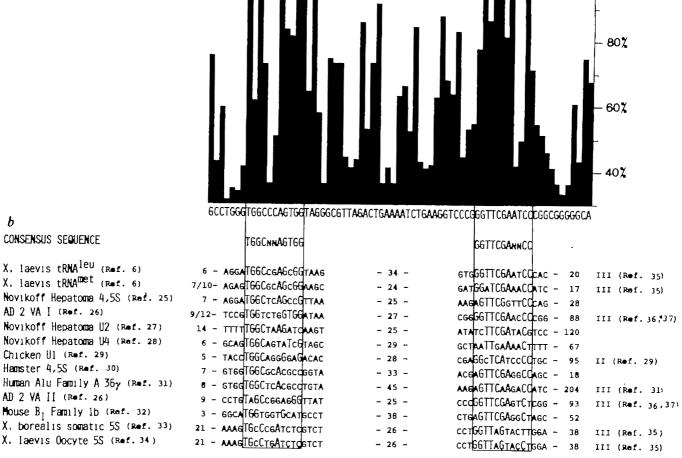

blocks have now been determined with some precision. By comparing the autoradiographic signals of the tRNA transcripts with that of the 5S RNA control, a rough estimate of the differences in tRNA production by the various injected clones can be made. Resection of the tRNA gene to position 5 is found to reduce transcription to a small degree (but curiously the product is now polydisperse and transcription termination is affected), whereas removal of sequences up to nucleotide 13 reduces transcription by a factor of about 20. Transcription is abolished altogether when the sequences up to and including nucleotide 16 are removed. This is in agreement with the tRNA mutants, where resection up to nucleotide 8 had little effect but resection up to nucleotide 12 reduced transcription to below the levels of detection.

Deletion of all 3' sequences, including the termination signal, up to +1 of the sequences located 3' to the structural gene, nevertheless permits transcription at a level of 70% of control. When the terminal 9 bp of the structural gene are removed up to and including position 65, transcription continues, albeit at a fourfold reduced level, but deletion of the next eight nucleotides completely abolishes transcriptional activity. The results therefore suggest that transcription is reduced as resection of sequences approaches the two gene-internal conserved

Fig. 4 Conserved sequence blocks A and B. a, The profile shows the frequency of occurrence of the most common nucleotide at every position in eukaryotic tRNAs as derived from a compilation of 80 eukaryotic tRNA's equences? The sequence of the most frequent nucleotides is given below the profile. The arrows (α, β, γ) above the profile indicate discontinuities in the compiled tRNA sequences. α, Nucleotide 17 is omitted because it is only present in 40% of the sequence tRNAs. β, Nucleotides 20 and 21 are separated by a variable number of nucleotides; thus, nucleotide 21 is not included in the A block γ, Location of extra arm. The consensus sequence for the A and B block includes all nucleotides which occur with a frequency of over 60%. Sequences of selected small cellular RNAs were taken from the references given on the left. They were aligned for maximal homology to the A and B block region. Nucleotides matching with the consensus sequence are shown with large letters. The numbers given on the left and on the right of each sequence represent the numbers of nucleotides to the initiation and termination points, respectively. The numbers in the middle show the number of omitted nucleotides. The roman numbers to the right of several sequences indicate which of the RNA polymerases transcribes the gene.

sequence blocks (underlined in Fig. 3; see below) but falls off precipitously when sections of these sequence blocks are removed. The internal sequences 21–37, as well as 47.3–50 can be replaced by *HindIII* linker and still support transcription of at least 40% of the wild-type level. This may be compared with the related tRNA<sup>met</sup> mutants, where substitutions of nucleotides 30–50 by *HindIII* linkers still permitted tRNA transcription, although at a reduced rate. These experiments show that gene sequences 21–50 can be replaced by foreign DNA, thus delimiting the gene-internal boundaries of most essential sequences. Note, however, that substitution of the entire sequence from 21 to 50 by *HindIII* linkers strongly inhibits transcription.

Thus, deletion and substitution of DNA segments around nucleotides 10–20 and 51–64 produces the most pronounced inhibition of transcription. Substitutions of small segments between these sequence blocks have smaller but nevertheless deleterious effects on transcription and these effects are apparently potentiated when several segments are removed together, as is the case for the 21–50 substitution. A picture therefore emerges for the tRNA<sup>Met</sup> and the tRNA<sup>Leu</sup> gene in which nucleotides particularly important for transcription promotion are seen to be clustered in two sequence blocks. Our unpublished findings that a minimal gene consisting entirely of DNA linkers and the above sequence blocks proved inactive in transcription indicate that these sequence blocks are necessary, but not sufficient, for initiation of tDNA transcription.

#### Conserved sequences in eukaryotic tRNAs

Figure 4a displays a profile showing the frequency of occurrence of the most common nucleotides at every position in eukaryotic tRNAs, as derived from a recent compilation of 80 tRNA sequences<sup>7</sup>. Two regions at positions 8-19 (A block) and 52-62 (B block) are highly conserved, with several nucleotides occurring at a frequency of 100%. The regions outside the A and B blocks exhibit a lower degree of nucleotide preference. Conservation of these sequences in both prokaryotic and eukaryotic tRNA sequences has previously been interpreted solely in terms of their importance to tRNA structure and hence protein synthesis; for instance, in the yeast tRNA Phe, positions 8, 9, 14, 15, 18, 19 and 54-56 are essential in stabilizing the tertiary structure of the tRNA molecule<sup>15</sup>. Our present work on the tRNA Leu gene has demonstrated that virtually all the nucleotides which are external to the conserved A and B blocks can be removed without eliminating transcription, while conversely, deletion of the conserved sequences abolishes transcription altogether. Hence, nucleotides in the A and B block have not only a function in tRNA structure but also in tRNA gene transcription.

If the conserved A and B blocks are the principal, functionally distinct promoter sequences, these blocks should be exchangeable between different tRNA genes without affecting their transcriptional activity. To test this idea we constructed two chimaeric genes which contained the 5' half of one and the 3' half of the other from the tRNA<sup>Met</sup> and the tRNA<sup>Leu</sup> structural genes and flanking sequences. Both chimaeric genes (Fig. 5, lanes 3, 4) were transcriptionally active in the frog oocyte. This focuses our attention again on the sequences held in common between these two tRNA genes and further suggests that the self complementarity of the acceptor stem sequences of tRNA genes is apparently not an important aspect of the tDNA promoter structure.

Another prediction of our model is that prokaryotic tRNA genes exhibiting strong A and B homologies should yield specific transcripts when tested in an eukaryotic transcriptional system. This was found to be the case for the tRNA<sup>Asp</sup> and the tRNA<sup>Trp</sup> of Escherichia coli (W. Folk, unpublished data). Conversely, the E. coli tRNA<sup>Tyr</sup> gene is not transcribed when injected into frog oocytes (cited in ref. 16), and this prokaryotic gene shows poor homology to the A block sequence. All these results strengthen our hypothesis that the two conserved homology blocks are important for the transcription of eukaryotic tRNA genes.

### Diversity of promoters for polymerase III

If we consider all bases occurring at a frequency of at least 60%within sequence blocks A (positions 8-19) and B (positions 52-62) in over 80 different eukaryotic tRNAs, a 'con-TGGCNNAGTGG (A block) sequence' GGTTCGANNCC (B block) can be abstracted. Note that in some tRNA genes one or two additional nucleotides interrupt the A block at position 17. Therefore, the last two Gs of the A block either do not need to be co-linear with other nucleotides or are dispensable for transcription in some tRNA genes. Fowlkes and Shenk reported that two such sequence blocks also occurred in the adenovirus VAI and VAII gene and the 4.5S RNA gene of hamster cells. After mapping essential promoter sequences somewhere between positions 9 and 72 in the VAI gene4 they speculated that this sequence motif may be involved in transcription of RNA polymerase III genes. This hypothesis has now been shown to be correct for the  $tRNA^{Leu}$  gene of X. laevis.

The A and B sequence homologies can be extended to other genes transcribed by RNA polymerase III, for instance, to members of the human AluI and the mouse B1 families (Fig. 4b). Surprisingly, similar conserved blocks are also found in some of the genes coding for the U-RNA series, which code for capped RNAs and are therefore generally assumed to be transcribed by RNA polymerase II. The B block homology is particularly striking for many of these genes and it would therefore be worthwhile to investigate the potential of these genes to be transcribed by RNA polymerase III. Note that for most of the genes listed transcription initiation occurs 10-13 bp 5' to the A block, and in all cases (except for the 5S RNA genes) within 7-16 bp 5' to the A block boundary.

In Fig. 4b the genes have been arranged in order of diminishing strength of A block homology. This places the X. laevis oocyte 5S RNA gene clearly at the bottom. It is doubtful whether the A block homology of the 5S RNA is actually statistically significant. Dissection experiments have shown the 5' portion of the gene to be largely dispensable in transcription promotion. However, more recent competition experiments also implicate the whole area from -11 to 28 (rather than a specific A block segment) in some transcriptional role 17. The internal control region of the 5S RNA gene positions 50-83, although containing the B block homology, is considerably

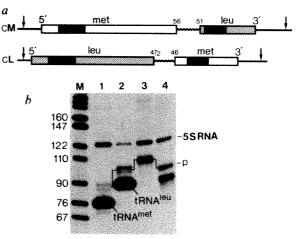

Fig. 5 Transcription of chimaeric tRNA genes. a, The chimaeric gene cM was constructed by combining, via HindIII linkers, the 3' half of mutant h (Fig. 3A) of the tRNA Leu gene with a tDNA Met fragment containing 120 bp of 3'-flanking sequences and the first 56 nucleotides of the structural gene 5. Lis a combination of the 5' part of mutant h (Fig. 3A) of the tRNA Leu gene with a tDNA Met fragment which contains 28 bp of the 3' end of the structural gene and stretches 90 bp into the 3'-flanking sequences<sup>5</sup>. Wavy lines represent HindIII linker DNA, black boxes show the location of the conserved sequence blocks, arrows at the 5' end and 3' end indicate initiation and termination points, respectively. b, Lanes 1-4, transcriptional analysis of wt and mutant genes. Incubation time after injection was 15 h. RNA from two oocytes was loaded on to the gel and the film was exposed overnight. Lane 1, tRNA Met wt; lane 2, tRNA Leu wt; lane 3, chimaeric gene cM; lane 4, chimaeric gene cL.

larger than the posterior control region of tRNA genes. Therefore, both the primary structure of the 5S RNA and the tRNA genes and their response to sequence manipulation suggest that there are at least two subclasses of RNA polymerase III promoters (see also below) which differ from one another in their arrangement and the relative importance of specific sequence blocks. Other genes known to be transcribed by RNA polymerase III seem to fall between these two extreme cases. The above grouping of the genes is further supported by the results obtained from cofactor separation. Faithful transcription of the *Xenopus* tRNA<sup>Met</sup> and the adenovirus VAI gene depends on similar protein fractions<sup>18</sup>, whereas the 5S transcription requires an additional cofactor which binds to the intragenic control region 50-83<sup>19,20</sup>.

From previous experiments with the tRNA<sup>Met</sup> gene unit<sup>5</sup> it can be calculated that the minimal distance between the A and B blocks (see Fig. 4b) is about 29 bp. The tRNA<sup>Met</sup> gene is one of the smallest genes transcribed by RNA polymerase III and in this gene the A and B block probably lie together in the closest proximity compatible with efficient promotion of transcription. However, the distance A-B in natural genes can be much larger, for instance, 41 bp in the Xenopus tRNA Leu gene or 68 bp in the

yeast tRNA<sup>Leu</sup> gene, which contains an intron<sup>21</sup>. It is therefore not surprising that the RNA polymerase III gene system can cope with tRNA<sup>Met</sup> genes distended by 30 bp<sup>1.5</sup> or with introns of the tRNA<sup>Leu</sup> gene of yeast, into which additional sequences have been inserted<sup>21</sup>. The intermediate coding regions of tRNA genes located between the conserved A and B blocks include the sequences coding for the anticodon loop, the extra arm of different length (see Fig. 1) and the insertion sites of naturally occurring introns. It is therefore this region that predominantly differs between the various tRNA molecules. In keeping with this, the split tRNA promoter permits variability not only from single base changes, but also from extension or shortening of the sequences lying between the A and the B block. This flexibility contrasts with the 5S RNA gene operator system where only a single major type of RNA is produced and where transcription initiation occurs at a fixed distance from a single gene-internal control sequence

# Human immunoglobulin D segments encoded in tandem multigenic families

U. Siebenlist, J. V. Ravetch, S. Korsmeyer\*, T. Waldmann\* & P. Leder

Laboratory of Molecular Genetics, National Institute of Child Health and Human Development and \* Metabolism Branch, National Cancer Institute, National Institues of Health, Bethesda, Maryland 20205, USA

A family of germ-line immunoglobulin D-region genes has been cloned and mapped at regular intervals along a 33-kilobase length of human chromosomal DNA. Each member of the family varies slightly in sequence, but precisely conserves the recombinational signals and spacing that flank each gene. This region seems to have been formed by the tandem amplification of large and still well conserved segments of genomic DNA. Further, structural comparisons of germ-line and rearranged D segments suggest that D segments may recombine with each other.

THE genetic information necessary to form an immunoglobulin molecule is encoded in separate segments of DNA that must be brought together to form a coherent gene 1-8. This process occurs in developing B lymphocytes<sup>9-11</sup> and is a central mechanism necessary for the creation of antibody diversity. Mouse immunoglobulin  $\kappa$ -chain genes, for example, are formed by joining one of several hundred germ-line V-region segments <sup>12,13</sup> to one of four active J regions <sup>14,15</sup>. These segments can be joined in different combinations and at slightly different cross-over points so that there are thousands of different possible end products 14-16.

Such recombination is thought to be mediated by special signals encoded 3' to each germ-line V-region sequence and 5' to

each functional J-region sequence 6-8,14,15. These signals are complementary to one another and consist of a small palindromic heptamer separated by an approximately 12- or 23-base spacer from an A- or T-rich nanomer. Thus, the consensus signal sequence, 5'-CACAGTG-12 base spacer-ACAAAAACC-3', occurs 3' to each V, gene, while the consensus sequence, -GGTTTTTGT-23 base spacer-CACTGTG-3', occurs 5' to each J<sub>s</sub> sequence. The sequences of the spacer regions are not conserved but their lengths apparently are. The conservation of these elements prompted the formulation of three rules for V-J recombination: the two signal sequences, each consisting of a nanomer and a heptamer part, must be complementary to each other<sup>14,15</sup>; recombination can occur only between a signal of 12

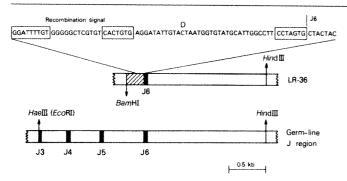

Fig. 1 Germ-line and aberrantly rearranged (LR-36) restriction fragments used for screening a Charon 28 phage library constructed from a partial MboI digest of human placental DNA. The novel DNA adjacent to J6 in LR-36 is depicted by cross-hatching; the nucleotide sequences comprising a D-like element are shown above. The LR-36 BamHI-HindIII fragment (1.9 kb) isolated from a pBR322 subclone was nick-translated to a specific activity of 200-500 c.p.m. per pg as described previously 32 and used to screen the phage library according to the Benton-Davis procedure 33. Fifteen hybridizing plaques were obtained and were rescreened with the embryonic HaeIII-HindIII fragment (~3 kb) in order to select those library clones that specifically hybridize to the novel germ-line D-like DNA shown by cross-hatching. (The embryonic HaeIII site was transformed into an EcoRI site by joining to the arm of the phage vector Charon 4A<sup>20</sup>.)

base pairs (bp) spacing with one of 23 bp spacing<sup>7,8</sup> and joining occurs near the ends of the heptamers, thus deleting the signal sequences in the recombinant<sup>14,15</sup>.

Formation of heavy-chain V-region genes follows these same basic principles but is somewhat more complex; it involves the joining of three separately encoded elements, a V and J sequence as well as an additional element that appears between them<sup>7.8</sup>. The additional segment, called D (for diversity), encodes a major portion of the third hypervariable region of heavy chains<sup>7.8.17</sup>. Because ~23-base spacers were found in the recombination signals that flank germ-line mouse  $V_H$  and  $J_H$  sequences, it was predicted that germ-line D segments would be flanked by recombination signals separated by ~12-bp spacers. Two initial examples in the mouse bear out this prediction<sup>18,19</sup>.

We set out to find and characterize such D-gene segments in man and to elucidate their organization and the extent of their representation in the human genome. The possibility of assembling V regions from three separate segments greatly increases the potential for generating diversity, but this potential immediately depends on the size of the germ-line repertoire of V, D and J region segments as well as the nature of the recombination event.

Our first requirement in any strategy designed to characterize germ-line D segments was to obtain a DNA probe containing germ-line D sequences so as to screen human genomic libraries. This posed a problem, because V-D-J recombinants generally contain only very short stretches of sequence derived from germ-line D segments and therefore are unsuitable as probes for screening. One way of circumventing this difficulty would be to isolate an intermediate in which the D segment had been joined to only one of its two eventual recombination partners, either the V or J segment. In this way, a longer segment of the germ-line sequence flanking the D segment would remain associated with the new V-D or D-J segment. We found such an intermediate, albeit somewhat aberrantly rearranged, in an IgM-bearing leukaemic lymphocyte in undergone rearrangement<sup>20</sup> chromosomes had chromosomal copy, the active one, had been produced by V-D-J recombination (LR-35); the other (LR-36) had been generated by joining a D-like segment to the 3'-most JH sequence, J6, to produce a D-J-type intermediate<sup>20</sup>. The 5 portion of this clone became our probe for a D-region family. We show below that this D segment is apparently encoded in a large although closely related family. Members of this family are widely but evenly spaced over a 33-kilobase (kb) segment of germ-line DNA, separated from one another by about 9-kb stretches of DNA. Surprisingly, these stretches are tightly conserved. The D segments vary slightly in sequence but retain their recombination signals. In addition, the structure of recombined D segments suggests that they might be shuffled, that is, recombine with each other, thereby further diversifying the third hypervarible region of heavy chains.

# D-gene segment has aberrantly recombined with a J region

Lymphocytes from patients with chronic lymphocytic leukaemia seem to represent the clonal expansion of a single differentiated cell. Both chromosomes of one such IgM-bearing leukaemic lymphocytic clone (CLL-LR) have rearranged with respect to the J<sub>H</sub> locus as discussed by Ravetch et al.<sup>20</sup>. One recombinant (LR-35) is presumed to be the active gene, giving rise to an expressed IgM molecule. The other recombinant (LR-36), however, has been generated by joining a D-like sequence with the 3'-most J<sub>H</sub> sequence, J6. This rearrangement is incomplete because V-gene sequences are lacking, and, furthermore, it is aberrant, because stop codons are located in phase with the J-coding frame. The new sequences brought in next to J6 include a recombination signal with a 12-bp spacer, as would be expected of such signals for the germ-like D segments 7.8,-8,-9 (see Fig. 1). Consequently, this aberrant rearrangement seems to represent a germ-line D-gene-like sequence joined to J6, thus providing us with a larger probe for germ-line D-gene segments.

To obtain germ-line D segments, we screened a human placental library constructed in the vector Ch28 by partial MboI

Fig. 2 Southern blot analysis of human placental DNA (a) and of fibroblast **(b)** DNA lymphocyte (c) from a leukaemic patient. Human **DNAs** were digested with the restriction enzyme BamHI, fractionated on a 0.8% agarose gel and then blotted on to nitrocellulose filters as described previously<sup>21</sup>. Filters were hybridized to the 1.8-kb germ-line BamHI fragment shown; this restriction fragment was derived from phage A3 shown in Fig. 3 and subcloned into pBR322. a, The probe hybridizes to itself (1.8-kb fragment) in addition to four more fragments 18, 7.4, 6.6 and 1.6 kb long. c. The germ-line D probe only hybridizes to those fragments located 5' to the D1 sequence which rearranged aberrantly with J6 (LR-36). Only the 18-kb and 6.6-kb fragments have been retained during DNA rearrangement in this B cell. (The rearranged fragment carrying the aberrant DJ6 recombinant (LR-36) is visible only after a long exposure as an about 12 kb band.) The fibroblast line (b)serves as a control and shows the same pattern seen in placental DNA

(a).

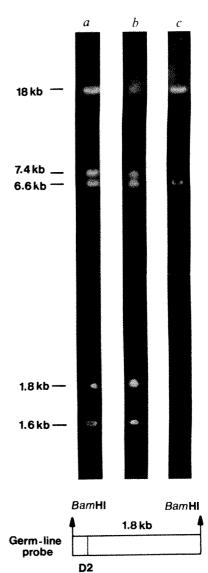

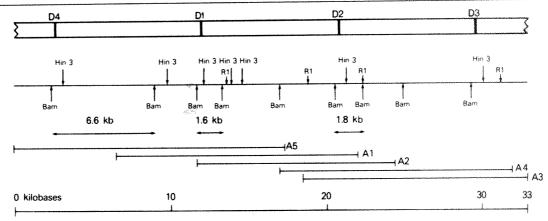

Fig. 3 Map of human linking four D locus separate D-gene seg-33 kb ments on genomic DNA. Shown are a partial restriction map, the approximate extent of phage clones used to construct this map and the three genomic BamHI fragments contained entirely on our clones (6.6, 1.8 and 1.6 kb long). D3 is located on a 7.4-kb genomic BamHI fragment (see which is only partially

contained on the phage A3. Phage clones A1-A5 overlap, whereas phage clone A6, containing only one D element (D5), has not been linked. The map illustrates the regular tandem arrangement of members of this family of D segments.

digestion. The fragment used as a probe is the 1.9-kb BamHI-HindIII fragment shown in Fig. 1, a D-J probe isolated from the aberrant recombinant LR-36. Fifteen hybridizing phage clones were isolated and then rescreened with an embryonic J probe (EcoRI-HindIII fragment in Fig. 1). Only those phage clones hybridizing to the D-J fragment but not to the embryonic J probe contain germ-line D-gene segments. In this way we obtained seven phage clones containing D-gene segments.

# D-gene segments exist as a family in germ-line DNA

To characterize the phage clones containing D-gene segments, the cloned DNAs were digested with BamHI and hybridized with the D-J probe (BamHI-HindIII in Fig. 1) according to the Southern blotting technique<sup>21</sup>. Such analyses revealed multiple BamHI fragments with D segments. A characteristic 1.8-kb D-segment-bearing BamHI fragment, found in four clones (A2, A3, A4 and A7), was subcloned into pBR322 and used as a germ-line D probe.

To confirm the appearance of multiple D-gene segments in the genome we digested total human placental DNA with BamHI and probed it with the 1.8-kb germ-line D fragment. As seen in Fig. 2a, this probe detects not only itself, but also four additional BamHI fragments of about 1.6, 6.6, 7.4 and 18 kb length. We conclude that D genes are indeed multiply encoded within the genome and are organized into gene families, reminiscent of V-gene gamilies.

# D genes are tandemly arranged on the genome

To learn more about the organization of D-gene segments we have mapped our phage clones with the restriction enzymes BamHI, HindIII and EcoRI. Two phage isolates are indistinguishable from each other (A7 and A4) and five different phage inserts overlap each other. These overlapping phages link four different D genes to each other on a 33-kb long DNA segment, as shown in Fig. 3. One additional phage, A6, is as yet unlinked and contains one D segment.

The map of this D-gene family locus reveals a surprisingly regular tandem arrangement of D genes, separated from one another by about 9 kb. It is not known whether these large spacer regions are functionally significant. Three D-containing genomic fragments of 1.6, 1.8 and 6.6 kb, detected in a BamHI digest of total placental DNA, are also present in our phage inserts. The remaining two genomic fragments of about 7.4 and 18 kb are likely to carry D3 and D5, located on the phages A3 and A6, respectively. In both cases, the clone inserts end within the genomic BamHI fragments. Consequently we have cloned all five identifiable members of this D-gene family, four of which are regularly spaced ~9 kb apart.

We established the 5' to 3' order of these gene segments by analysing genomic DNA from chronic lymphocytic leukaemia cells (CLL-LR). As discussed above, these differential leukaemic B cells have rearranged both chromosomes to give rise to an active (LR-35) and to an aberrant (LR-36) recombinant. Assuming that recombination is accompanied by a deletion of intervening DNA<sup>22</sup> and that D genes reside between V and J genes, the chromosome carrying the active V-D-J gene should not contribute any germ-line D-gene fragments. The chromosome carrying the aberrant D-J6 recombinant, however, is expected to have retained those germ-line D-gene fragments located 5' to the aberrantly recombined D, while deleting those fragments located 3'.

Accordingly, we probed a BamHI digest of DNA from CLL-LR with the 1.8-kb BamHI fragment which contains germ-line D sequences; a DNA digest of a fibroblast line established from the same patient served as a germ-line control. As Fig. 2c shows, the D-bearing germ-line fragments of 1.6, 1.8 and 7.4 kb length have been deleted in the leukaemic B cells relative to the germ-line pattern (Fig. 2b). This orders the retained 6.6-kb long, D4-bearing fragment to the 5' side of the deleted 1.6-kb (D1), 1.8-kb (D2) and 7.4-kb fragments (see Fig. 3). According to the map order in Fig. 3, D3 must be deleted along with D1 and D2 and must therefore reside on the 7.4-kb germ-line fragment. (The only other genomic band, 18 kb long and as yet unlinked, is not deleted in this B cell.)

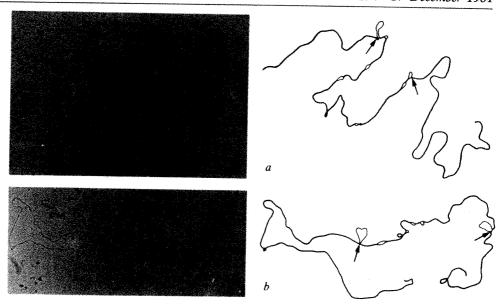

# D regions are embedded in 9-kb repeat units of DNA

To identify possible homologies around D-gene segments, we heteroduplexed phages A5 and A3 with each other. Inserts within A5 and A3 do not overlap and so any heteroduplex formed between them is indicative of sequence homology, but not identity. Surprisingly, the two phages form a heteroduplex structure not only around the D segments, but almost throughout their entire lengths (see Fig. 4a). This extensive homology is interrupted only by several small nonhomologies in addition to deletion loops at the ends of inserts; such deletion loops are expected because different clones are unlikely to end in similar positions within the homology. Several of these small regions of nonhomology vary in size between molecules and occasionally are not visible, suggesting that even these regions have some homology, although not usually sufficient for heteroduplex formation.

Similarly, we can demonstrate homology between all the spacer regions surrounding these D segments. For example, the overlapping phage inserts of A3 and A2 (see Fig. 3) heteroduplex in a way which shows the spacer homology rather than identity of sequence in the overlap; such a heteroduplex is shown in Fig. 4b.

This locus of the human genome then appears to consist of 9-kb long repeat units, apparently arranged end to end, with each unit encoding one D-gene segment of this family. Such an organization is likely to be the result of very recent duplication

Fig. 4 Electron micrographs and schematic representations heteroduplexes formed betweeen phage clones containing D segments. Methods for heteroduplex formation have been described elsewhere Phages A5 and A3 form an extensive heteroduplex, although their inserts do not overlap (see Fig. 3). Spacer DNAs between these D segments are homologous to each other. b, Phages A2 and A3 similarly form an extensive duplex. Pairing of the imperfect, though large spacer homology is preferred over pairing of the smaller region shared by these two overlapping phages (see Fig. 3). The spacer homology for both a and b is interrupted by a few small mismatched regions. The extent to which some of these small mismatch loops form varies slightly between heteroduplex molecules, although the overall pattern of these mismatch

regions is preserved and is found reproducibly in more than 10 molecules examined. Phage insert end are indicated by arrows. Deletion loops at the insert ends merely show that the two phage clones do not end at identical positions within the homology.

events. Nonetheless, mechanisms that operate to maintain sequence homologies within the spacer cannot be ruled out.

#### Germ-line D-gene segments are surrounded by recombination signals with 12-bp spacers

To establish formally the existence of D segments on our clones and to allow further characterization, we sequenced the relevant regions using the Maxam–Gilbert procedures. Figure 5 shows four such embryonic D sequences of this family. All are surrounded by recombination signals with a 12-bp spacing between the heptamer and nanomer sequences. This allows for recombination with signals of about 23 bp spacing, as are found on the 3' side of  $V_{\rm H}$  genes<sup>7,8,23–25</sup> and the 5' side of  $J_{\rm H}$  segments<sup>7,8,20,26</sup>, and as would be required by the 12/23-bp spacing rule.

The sequences within and surrounding these D segments are closely homologous to each other, differing mostly by point mutations, except for a deletion of a triplet in D3. Most of the nucleotide differences lie within the potential coding sequences (that is, between the recombination signals) and in particular near the middle of these segments. The recombination signals and spacers, on the other hand, particularly those on the 5' side, are very strongly conserved. Surprisingly, the 5' and 3' spacer sequences are quite complementary to each other and, together with the complementary recombination signal, an extensive stem structure could be drawn, looping out the D-coding segment.

D sequences of different families are heterogeneous in length. The presumptive coding blocks of this family of D segments are 31 bp long (D3 has 28 bp). DHQ52, a D segment interspersed

among J regions in man and 5' to J segments in mouse, is 11 and 10 bp long, respectively 18,20; DSP2.2 in mouse encompasses 17 bp 19. Observed size variations in the third hypervariable region of heavy chains 27 may reflect length heterogeneity of D segments.

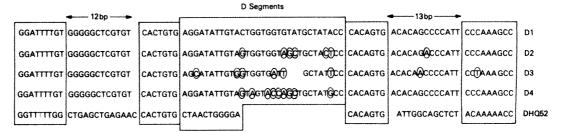

The diversification of variable regions contributed to by D segments increases even further when we consider the inherent flexibility associated with recombination events<sup>14,15</sup>. Flexibility in the exact point of joining has been demonstrated for V-J recombination in light chains; for example, V and J segments are sometimes joined out of phase with each other<sup>28</sup>.

In contrast, D segments have no known coding frame. Therefore, if we assume a flexible recombination mechanism, all three reading frames of D sequences are potentially usable. This would further diversify immunoglobulins of different B cells. In this context, all three reading frames of D1 are open, that is, they do not contain any stop codons, while D2, D3 and D4 each have two open reading frames.

# Is aberrant D-J the result of more than one recombination event?

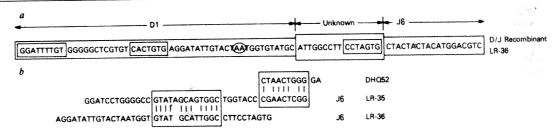

As discussed above, only D1 can be the parent of the aberrant D-J6 recombinant. Germ-line DNA between D1 and J6 has been deleted during recombination (Fig. 2c) and sequence analysis confirms this assignment (see Fig. 6a). Sequences within 200 bp 5' of D1 are identical to those 5' to the D-J6 recombinant, as determined by restriction mapping and partial sequencing. All other members of this family (including D5 on phage A6) exhibit similar, but clearly different sequences.

Fig. 5 Nucleotide sequences of four members of this human D family (D1, D2, D3, D4) in addition to DHQ52, published elsewhere<sup>20</sup>. The D4, D2 and D3 sequences are compared with D1 and differences are shown by gaps or encricled bases. The

the D segments are boxed—all contain a 12- or 13-bp spacer between the heptamer and nanomer parts. No other recombination signals are found in the immediate flanking sequences (not shown here). All four D segments were sequenced according to the Maxam and Gilbert procedures<sup>35</sup>. D1 was sequenced from a 400-bp long BamHI-HindIII fragment, whereas D4, D2 and D3 were sequenced from 800-bp long BamHI-HindIII fragments (see Fig. 3). (These fragments were obtained by restriction of subcloned BamHI fragments (see Fig. 3).) D segments were located by random sequencing within these fragments. Sequences were determined in both directions. The four D segments are much more closely homologous on their 5' sides than on their 3' sides, although they all show extensive homology except near the middle of the coding segments. D3 has deleted a triplet whereas all other differences are point mutations.

Fig. 6 a, Parents of the D-J recomaberrant LR-36. The binant nucleotide sequence of I R-36 is derived entirely from the D1 parent and J6 parent except for 16 bp immediately adjacent to J6 (designated 'unknown' here) and 2-bp mutations 10 bp 5' to the

unknown DNA (circled here). This novel DNA contains a heptamer-like recombination signal and may represent the 3' end of an unidentified D segment which recombined with D1. Recombination signals are boxed. b, The active recombinant LR-35 sequence shows segmental homologies with the LR-36 sequence and the DHQ52 germ-line segment. Homology regions are boxed. LR-35 seems to derive parts of its sequence from D segments also used by the aberrant recombinant LR-36, but in addition shows homology to DHQ52. This suggests that different D segments may have recombined with each other to form a mosaic LR-35 sequence. (Interestingly, the region shared by LR-35 and LR-36 spans the presumed recombination point in LR-36 (see part a of this figure).)

Although most of the coding segment of D1 is preserved during recombination, the six 3'-most base pairs of D1, are not found in the recombinant. Instead, 16 bp of unknown origin appear directly adjoining J6 (see Fig. 6a). What gave rise to these sequences? As this sequence arrangement is not present in germ-line DNA, we must invoke an additional rearrangement: D segments may be able to recombine with each other. Within the 16 bp of unknown origin we find a heptamer-CCTAGTG—which resembles the heptamer consensus sequence for recombination signals. This may be a remnant of the 3'-recombination signal attached to an unknown D sequence which recombined with D1; joining to J6 did not completely eliminate the signal.

The parent sequence D1 and the recombinant LR-36 also differ in two adjacent nucleotides within the otherwise preserved D sequence (10 bp 5' to the presumed D-D joining site, see Fig. 6a). These point mutations might have arisen somatically, either connected with or independent of the recombination event. Also possible is a polymorphism in the DNA sequence of this patient. Although less likely, we cannot rule out the possibility that D1 recombined with another D 5' to the two nonmatching nucleotides. This would require part of the unknown D segment to be identical with D1.

The presumed active recombinant LR-35 provides further, albeit indirect, support for the D-D recombination proposal. Part of the LR-35 gene sequence is quite homologous to a sequence in the D segment of the aberrant recombinant LR-36; beyond this homology region, the two sequences diverge. However, the LR-35 D segment also has some additional homology with another germ-line gene segment, DHQ52. This homology is 3' to the homology it has with LR-36 (see Fig. 6b), which suggests, but does not prove, that at least three different D segments have contributed to the LR-35 D; that is, that multiple recombinations between D segments can generate active Dregion segments.

At present we do know how D segments recombine with each other because no appropriately situated recombination signals exist to accomplish such joining. In light of existing recombination events, we would expect recombination signals conforming to the 12/23-bp spacing rule next to the eventual joining sites of the two D segments. We see no such signal next to the presumed site of rearrangement in the germ-line D1 sequence. On the other hand, it has been suggested that such a signal exists in some mouse segments29. It is possible, however, that the extensive homology that surrounds the D-region sequences has a role in their interaction, either somatically or within the germ line. Such a mechanism, involving homologous recombination or gene conversion, would allow segments to amplify their germ-line diversity in much the same way as has been proposed for members of V-region families<sup>12</sup>. Clearly, the resolution of this question will depend on the further analysis of germ-line and rearranged D-region genes.

#### D-gene segments can generate enormous diversity

The variable region of the heavy chain derives its diversity from four principal sources: multiply encoded V-, D- and J-gene segments; a combinatorial joining mechanism; flexibility in the exact site of recombination that can generate different amino acids at junctions between joined segments (in the case of D segments, this flexibility allows reading in different frames); and a potential for solitary somatic mutations, an additional process now being documented<sup>24,25,30,31</sup>

The most diverse portion of the heavy chain is the third hypervariable region. This is understandable in terms of what we know of D-region genes. Not only are D segments multiply encoded, but these short sequences of variable length might also recombine with each other. Flexibilty at the site of joining further diversifies junctions between V, J and other D regions and could create different reading frames within D segments. This system is therefore able to generate an enormous amount of coding information, particularly within the third hypervariable region, providing a major source of diversity.

We thank Barbara Norman for assisting us in our electron microscopic studies, Marion Nau for helping to construct human libraries, and to Terri Broderick for her assistance in the preparation of this manuscript.

#### HR 465 returning to rare-earth-maximum phase

Charles R. Cowley\*

Dominion Astrophysical Observatory, 5071 W. Saanich Road, Victoria, British Columbia, Canada V8X 4M6

John B. Rice

Brandon University, Brandon, Manitoba, Canada R7A 6A9

HR465 is unusual among Ap stars. Its spectroscopic variability has been discussed by Wolff and Preston<sup>1</sup> who show that at the rare-earth-minimum phase, the sharp-lined spectrum is similar to that of many other Ap stars of the 'magnetic sequence'. The rare-earth-maximum phase, studied Bidelman and Pyper (personal communication), was found to have an extremely high density of lanthanide rare-earth lines in addition to Hg II 3,984Å. Their observations of this phase were made in the early 1960s and because of the very long period of the star, around 22-24 yr, they have not been repeated. Until recently, the critical phase of HR465 has been unavailable. However, we report three 2.4Å mm<sup>-1</sup> spectrograms of HR465 taken at the Dominion Astrophysical Observatory (DAO) in August 1981 which show that the spectrum now very closely resembles that of the early 1960s—the rare-earth-maximum phase has returned.

Aller and Cowley's<sup>2</sup> announcement of the possible presence of the unstable element promethium, whose longest-lived isotope has a half life of only 18 yr, in the spectrum of HR465 caused much interest. Setting aside this controversy<sup>3,4</sup>, the rareearth-maximum spectrum of HR465 is of great interest. The elemental abundance patterns<sup>5,6</sup> suggest the presence of r-process peaks. Ohnishi<sup>7</sup>, and Steinberg and Wilkins<sup>8</sup> have discussed possible interpretations of these abundances in terms of fission. There are strong arguments<sup>9</sup> for the presence of the actinide rare earths uranium and thorium. An unusual distribution of wavelength residuals suggest that the uranium may contain a high percentage of isotopes lighter than 238. A possible uranium-to-thorium ratio greater than unity could be interpreted in terms of a recent r-process event, and the excess uranium would then be due to the presence of isotopes lighter than 238 (ref. 10).

The star has been monitored at the DAO since 1974. In 1979 and 1980, substantial increases in the line density were noted, as well as a progressive strengthening of lines of the heavier lanthanides, notably dysprosium. Particular attention was paid to the feature near 3,859.6Å, which closely coincides with the wavelength of the strongest U II line11. This feature, which is dominated by Cr I in most magnetic Ap stars, weakened througout the late 1970s along with the Cr I and II spectra. There is a pronounced weakening of Cr I throughout this period.

In the August 1981 spectra, 3,859.6Å has strengthened considerably; it may now be considered a moderately strong line (~80 mA). Figure 1 shows tracings of the region of UII 3,859.6Å made from spectrograms taken at the previous rareearth maximum (A), an intermediate epoch (B), and in August 1981. The top two tracings have been described and detailed line identifications given elsewhere<sup>12</sup>. Figure 1C shows DAO plate no. 13891, taken in August 1981. Filled squares below the absorption lines mark features which have been wholly or partially identified as due to lanthanides. While most of the features in the rare-earth-maximum spectrum are marked with squares, only three features are so marked in Fig. 1B, where many of the absorptions are due to chromium.

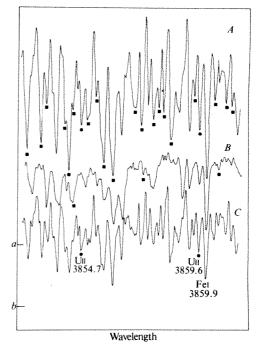

Fig. 1 Direct intensity tracings of HR465 taken on September 1961 (A), November 1974 (B) and August 1981 (C), in the region of the strong U II lines at 3,854.7 and 3,859.6Å (•). The strong Fe I line is at 3,859.91Å. Lanthanide lines are indicated by solid squares (). A one-to-one correspondence of features in the A and C is apparent. Zero intensities for A and B are marked a and brespectively. The base is zero for C

Wavelengths for one of the current DAO plates have been measured from PDS scans using a program developed by Rice. Positions for 4,143 lines in the region 3,707-4,655 Å were analysed by the method of wavelength coincidence statistics (WCS)<sup>13</sup>. Essentially the same heavy ion species that were present at the last rare-earth maximum can again be identified. In particular, dysprosium (Dy III is especially strong), Ho and Er are identified at very high confidence levels. The 1981 plate shows good statistical evidence for the presence of osmium, and marginal evidence (98% confidence) for platinum. The presence of both of these transition metals has been found at less exotic

WCS of the 1981 plates show marginally significant results for U II (97.5% confidence), Th II (97.5% confidence) and Th III (99.5% confidence).

The present observational material (2.4Å mm<sup>-1</sup>) is not good enough to allow us to extract definitive information on the critical isotopic abundance ratios. Very high resolution and low noise are needed. Many features must be studied because of the severe problem of blends.

For the next few years, HR465 will be in a critical phase which deserves intensive investigation.

We thank director van den Bergh for use of the facilities of the DAO, also W. A. Fisher, J. M. Fletcher, S. C. Morris, and R. H. Poeckert for help with instrumentation and programming. This research was supported in part by the NSF and the Natural Sciences and Engineering Research Council of Canada.

## Supernovae and nitrate in the Greenland Ice Sheet

## T. Risbo\*, H. B. Clausen† & K. L. Rasmussen‡

\* Institute for Geophysics, University of Copenhagen, Haraldsgade 6, 2200 Copenhagen N, Denmark † Geophysical Isotope Laboratory, University of Copenhagen, Haraldsgade 6, Copenhagen 2200 N, Denmark ‡ Physics Laboratory 1, H. C. Ørsted Institute, University of Copenhagen, Universitetsparken 5, Copenhagen 2100 Ø, Denmark

Nitrate concentration in the absolutely dated Greenland ice core from Crête has been measured for six time intervals, five surrounding the time of appearance of the well established historical supernovae during the past 1,000 yr and one during the Maunder minimum of solar activity, to look for a possible correlation between supernovae and nitrate concentration. The findings of Rood et al. of nitrate spikes corresponding to the appearance of the historical supernovae and a pronounced minimum in nitrate contents during the Maunder minimum are not confirmed. A very regular annual variation of nitrate concentration is observed superimposed on a constant background. We show here that both these signals seem unaffected by the known variations in the solar activity for the periods analysed. The nitrate contents are unaffected by peaks in acidity caused by volcanic eruptions. The annual variation of nitrate concentration suggests it could be used for dating ice cores.

Nitrate deposited in the Antarctic Ice Sheet has attracted attention because of its possible production by the absorption of ionizing radiation from extraterrestrial sources in the stratosphere 1-3. The deposition rate of nitrate in snow accumulated in areas remote from soil and sea should then reflect the influx of radiation from space, modulated by atmospheric processes such as exchange between the troposphere and stratosphere and the general tropospheric circulation. If this were true, the concentration of nitrate in polar glacial ice may contain information on solar activity variations, galactic cosmic-ray influx and changes in the atmospheric circulation connected with climatic changes.

Rood et al. have discussed whether the flash of X rays from a supernova explosion in our Galaxy might produce sufficient NO in the stratosphere to produce a spike of nitrate in ice cores a year or two after the event. In an Antarctic ice core they report four spikes with a factor of 2-3 higher than the background level. Three of the spikes seem to coincide reasonably well with the supernovae observed in 1181, 1572 and 1604. We know of no absolute dating for the South Pole station core in question and the expected accuracy of the dating is not reported by Rood et al.1. Three proposed datings differ ~40 yr for the AD 1181 event. The fourth nitrate event, at about 1300, is not correlated with any known historical supernova. Rood et al. report further indications of variation of the background level with the solar cycle and claim a pronounced low level of nitrate coinciding with the Maunder minimum of solar activity.

The perspective of these observations and the availability of the absolutely dated Crête ice core, induced us to measure nitrate in the Greenland ice. The fact that the historical supernovae predominantly lighted the Northern Hemisphere suggests that detection is more likely in Greenland than in Antarctica.

Supernova explosions are rarely observed in our Galaxy: Table 1 lists the data for the five historical supernovae observed in the past 1,000 yr. Data are partly historical and partly from recent optical and radio observations of the remnants4.

A supernova, Cas A, is believed to have occurred around 1750, but as the time of appearance is based only on extrapolation of present-day observations of the remnant it is not considered here. The next candidate before 1006 is AD 393 (ref. 4) which is out of range of the ice core material available for this study. However, the material does include the Crab supernova of 1054 and notably the year 1006 event, which is the one closest to the Solar System and the brightest new star ever observed.

The 404-m polar ice core used in this study was recovered using a thermal drill in a dry hole in Central Greenland 71 °N, 37 W in 1974 by the US Cold Region Research and Engineering Laboratory under the US-Swiss-Danish program Greenland Ice Sheet Program (GISP). The core handling and storage procedures have been described by Langway<sup>5</sup>, and the sample preparation by Hammer<sup>6</sup>. For the time intervals in question the ice core is dated to an accuracy of ±1 yr back to AD 1104 and  $\pm 3$  yr back to AD 553, which is the age at the bottom of the core. The dating is done by counting seasonal variations of the stable oxygen isotope ratio,  $\delta^{18}$ O, and acidity downwards from the surface'. The acidity curve provides the time scale with fix points back to AD 1104 using historical accounts of volcanic activity in the Northern Hemisphere. A volcanic eruption causes an increase of the acidity of the polar ice, the size of the signal found in the ice depends on the magnitude and geographical latitude of the eruption. All sample collections are based on continuous sequences of 12 ice samples per calculated annual layer for  $\delta^{18}$ O and acidity, and in general of four samples per calculated year for nitrate. The theoretical thickness of an annual layer at a given depth is calculated from a flow model for the ice sheet7. The mean annual accumulation at Crête is 29 cm of ice and the thickness of a calculated year AD 1000 is ~25 cm. Extreme care was taken to ensure no contamination of the samples for nitrate analysis. Samples of about 10 ml were cut in a laminar flow bench and a microtome knife used to clean the ice surfaces. Several centimetres of ice were cut away from the surface of the core. The samples were taken from crack-free regions of the core. The clean samples were put into sealed plastic beakers and kept at -20 °C. Melting was done just before the chemical analysis for nitrate.

The nitrate concentration (given as  $\mu$ equiv. NO<sub>3</sub> per kg ice) was measured as nitrite after reduction in a cadmium column. The nitrite was converted into a form of an azo dye by adding sulphanilamide and n-(1-naphthyl)-ethylene diamine dihydrochloride. The optical absorption of the dye solution was measured. The reproducibility of the method,  $\pm 0.02$   $\mu$ equiv.  $kg^{-1}$  (±2%), was achieved during the single runs of analysis. For comparison of the absolute levels between the six series of meaurements an accuracy of 5% was obtained: the source of error was the uncertainty in the dilution factor for the standard solutions used for the calibration. The measured quantity is the sum of nitrate and nitrite. The concentration of nitrite was measured on a few of the samples by bypassing the cadmium reduction column. The contents were always consistent with zero within the quoted measuring accuracy. The measurements are therefore assumed to give the nitrate concentrations.

Figure 1 shows the results of the nitrate analysis for the six short series of the selected time intervals covering the years before and after the appearance of the historical supernovae listed in Table 1. Also shown are curves giving the acidity from conductivity measurements together with  $\delta^{18}$ O data. The  $\delta^{18}$ O

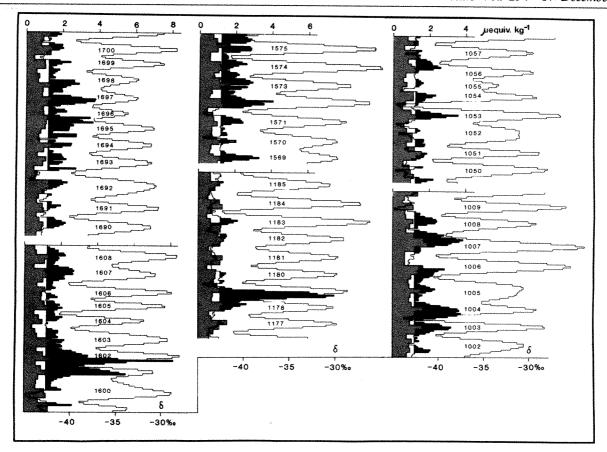

Fig. 1 Three curves for each of the six time intervals. Nitrate concentration (stippled area: left-hand scale  $\mu$ equiv. NO $_3^-$  per kg ice). Acidity fallout (black area: left-hand scale  $\mu$ equiv. H $^+$  per kg ice). Acidity above the background 1,2  $\mu$ equiv. kg $^{-1}$  are due to fallout of volcanic acids, mainly H<sub>2</sub>SO<sub>4</sub> and HCl, from eruptions in the Northern Hemisphere.  $\delta^{18}$ O to the right with scale at the bottom (per  $10^3$ ).

curve is first order corrected for diffusion  $^{10}$ . The beginning of a calendar year is arbitrarily defined as the point where the corrected  $\delta^{18}$ O begins to rise. The nitrate curve is represented by a mean of four samples per calendar year. By distributing and assigning the measured amount of nitrate to the calendar years defined above, one arrives at the mean nitrate concentration in calendar years. Figure 2 shows the annual deposition determined in this way. At the end of each curve the mean value and the standard deviation of the annual values are indicated. The bars reflect the variability of the phenomenon, the experimental errors in the chemical analysis being an order of magnitude smaller. The uncertainty in placing the divisions between calendar years also contributes to the standard deviation. No significant enhancement beyond the normal variations in nitrate

deposition is observed in the years of the five supernovae or the years following these events. From the accuracy of the absolute dating we conclude that the analysed portions of the ice core cover the times of appearance of the five supernovae. The curve for the interval AD 1690-1700, which is selected to represent the Maunder minimum, shows that nothing unusual is taking place, the mean deposition of nitrate is at the same level.

The correlation between nitrate and  $\delta^{18}$ O data is good. Like  $\delta^{18}$ O the nitrate shows a regular annual variation that is clearly visible, although there are only four samples per calculated year. Both curves indicate concordantly the fluctuations in the annual amount of precipitation. The annual variation in nitrate deposition seems to be the same for the six time intervals observed, sampling a period of 700 yr. Both the variation and the mean

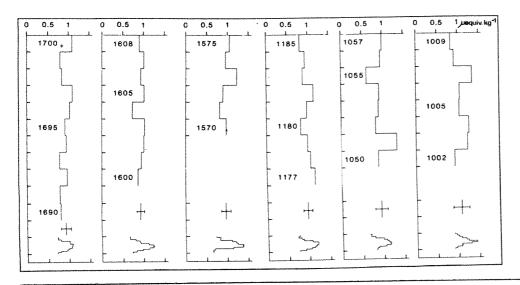

Fig. 2 Calendar annual means of nitrate concentration in μequiv. kg<sup>-1</sup>. The bars indicate the formal standard deviation and mean value of the calendar values, that is they do not reflect the experimental precision of the chemical analysis. The inset at the bottom shows the mean annual variation calculated by signal averaging from the original data of Fig. 1.

level in nitrate deposition seem to be independent of the recognized variations in solar activity during the Maunder minimum<sup>11</sup>. Figure 2 also shows the mean annual variation curves in nitrate deposition which were obtained by a signal averaging procedure<sup>12</sup>. From the measurement in Fig. 1, 12-monthly values are read evenly distributed in each calendar year. Average values are then taken for each month. The curves indicate an increase in nitrate deposition in the spring and a decrease in the autumn. The trough to peak variation is ~0.5  $\mu$ equiv. kg<sup>-1</sup> and the background is ~0.75  $\mu$ equiv. kg<sup>-1</sup>.

There seems to be no variation of the amplitude of the annual oscillation with an 11-yr sunspot cycle. The solar activity is, however, not well recorded in pre-telescopic time11 and conclusions must wait for a comparison with nitrate data from a

longer and more recent period.

The six time intervals contain two events in acidity ascribed to volcanic eruptions9. One is in AD 1178-1179 and correlated with an eruption of Katla, Iceland. The other is in AD 1601-1602 and not identified. Note that the nitrate curve goes undisturbed through the volcanic peaks. The acidity peaks are mainly composed of sulphuric and hydrochloric acids

The regular annual oscillation in nitrate contents makes it in principle possible to date ice cores by observing the nitrate signal, especially in polar ice from regions where no summer melting occurs (such as at Crête) and thus no percolating melt water penetrates the snow and disturb the stratified layers. We suggest that the higher deposition rate of nitrate in the summer is due to a stratospheric fallout following the opening of an tropospheric-stratospheric exchange every spring. The modern nitrate deposition in rain water in areas of Scandinavia, remote from industrialized regions, is at the level of 2  $\mu$ equiv. kg<sup>-1</sup>, and the natural pre-industrial deposition rate can be set to the level of 1 µequiv. kg<sup>-1</sup> judged from the lowest observations in northern Scandinavia<sup>13</sup>. The winter level of deposition in the Greenland ice is of the same magnitude and is therefore consistent with a residual tropospheric contribution in the clean air conditions above the Greenland ice.

It has been suggested that supernovae occurring close to the Solar System will enhance production of NO in the stratosphere and consequently produce observable nitrate peaks in ice cores<sup>14,15</sup>. As shown here the supernova (SN1006) occurring as close as 1,300 pc, caused no such effects in the Greenland ice. Candidates closer than that are the supernovae corresponding to the young short period Vela pulsar, the Lupus Loop, the Cygnus Loop and the North Polar Spur. The ages of these supernova remnants are estimated to be in the range 10,000-100,000 yr 16 This matches the time interval for which glacial material is available from the Antarctic and Greenland Ice Sheets. A local bubble of hot interstellar material observed in soft X-rays is considered to have originated from a supernova having exploded very near (<18 pc) the Solar System (R. Rothenflug, M. Arnaud & A. Soutoul, personal communication and ref. 17). If nitrate events in ice cores could be found and correlated with close supernovae an accurate dating of these is possible using the glacial record, and information on emission of  $\gamma$  rays and cosmic rays and their propagation to the Solar System could be obtained.

We thank Arne Nielsen for the opportunity to perform the nitrate analysis at the Marine Pollution Laboratory of the National Agency of Environmental Protection, Copenhagen. Rikardt Pedersen made the analyser run in the wanted mode and Margit Bernth and Hannah Thorp Petersen made much of the analysis work.

## Deuterium/hydrogen ratios in unequilibrated ordinary chondrites

N. J. McNaughton\*, J. Borthwick†, A. E. Fallick† & C. T. Pillinger\*

\* Planetary Sciences Unit, Department of Earth Sciences, University of Cambridge, Cambridge CB2 3EQ, UK † Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow G75 0QU, UK

The discovery of oxygen of anomalous isotopic composition in the Allende meteorite during the early 1970s led to the detailed investigation of primitive materials for unusual isotopic signatures. One element studied was hydrogen; major enrichments in deuterium relative to terrestrial and proposed nebula compositions have been discerned by close examination of specific phases within various meteorite samples. Here we report high and variable deuterium enrichments in two of the most unequil-Ibrated (unmetamorphosed) type LL3 ordinary chondrites, Bishunpur and Semarkona. Water released from bulk unseparated material by pyrolysis has  $\delta D$  values up to  $\sim 3,000\%$ (SMOW) or in absolute terms a D/H ratio of  $\sim 6 \times 10^{-4}$ . Thus, one of the highest deuterium contents yet encountered for a Solar System species has been observed without considering a specific fraction of a sample. Either these meteorites contain a greater proportion of the D-rich phase first recognized in meteorite separates, or a small fraction having an even more extreme deuterium content resides within them.

Variations in deuterium abundance are usually small and are reported relative to standard mean ocean water (SMOW):

$$\delta D = \left[ \frac{(D/H)_{\text{semple}} - (D/H)_{\text{SMOW}}}{(D/H)_{\text{SMOW}}} \right] \times 1,000\%$$

Hydrogen in terrestrial waters and other materials has a range of isotopic compositions falling within several hundred per mil of the absolute D/H ratio  $(1.56 \times 10^{-4})^2$  of SMOW<sup>2</sup>.

Before 1977 only two studies of meteorite D/H ratios had been attempted. Both concerned carbonaceous chondrites and had given inauspicious results in terms of anomalous compositions. Boato<sup>3</sup> recognized adsorbed or terrestrially exchanged H<sub>2</sub>O which could be removed by heating at temperatures up to 200 °C and more significantly, he found hydrogen (probably from hydrated silicates and organic matter) released at higher temperatures was enriched (up to 300%) in D relative to SMOW. Briggs<sup>4</sup> studied D/H ratios of solvent extractable organic materials; again enrichments up to 200% were encountered which led him to argue for an extraterrestrial origin for the compounds investigated.

More recently Robert et al.5 have studied ordinary chondrites in an attempt to differentiate between water from hydrated minerals and from the decomposition of organics. All the samples considered, with the exception of Chainpur, an LL3 chondrite, were within the terrestrial range. Subsequent investigations  $^{6,7}$  with material separated from Chainpur suggest the existence of a phase(s), labile between 450 and 750 °C and occurring with or within chondrules, which has a  $\delta D$  value of +2,000 to +4,400%; that is, containing a factor of ~5 times more deuterium than SMOW, an enormous enrichment by terrestrial standards. Kolodny et al.<sup>8</sup> reappraised the organic hydrogen in carbonaceous chondrites and postulated the presence of organic material in the meteorite Renazzo with a &D of +1,600% relative to SMOW. This effort was criticized 9.10 on

the grounds that the low-temperature oxygen plasma used to remove the organics selectively, in fact removed more hydrogen than could be accounted for by the original organic content; the material balance calculations used by Kolodny et al.<sup>8</sup> did not allow for this. Robert et al.<sup>9</sup> and Robert and Epstein<sup>11</sup> investigated extractable and polymeric organics from the Murray meteorite and measured directly D enrichments approaching +1,000% in this specimen, whereas Smith and Rigby<sup>10</sup> obtained  $\delta D$  values of +450% for acid insoluble residues from several carbonaceous chondrites.

While carbonaceous chondrites have been extensively studied for their hydrogen isotopic contents, primitive unequilibrated ordinary chondrites, except for Chainpur, have largely been ignored. It is now accepted 12.13 that class 3 unequilibrated meteorites may be further subdivided according to the degree of unequilibration 14; the number of subdivisions may be up to 10 (ref. 12). Although there is some disagreement as to whether Chainpur is one of the most unequilibrated examples of the class, it is accepted that three LL3 samples, Bishunpur, Krymka and Semarkona may be considered the most primitive 12.13. If the anomalously heavy hydrogen in Chainpur is a pre-Solar System remnant, it might also be found in these particular specimens.

Preliminary experiments on material from close to the fusion crust of a small sample from Bishunpur showed that water could be extracted with a  $\delta D$  value of between +2,489 and +3,109% SMOW (ref. 15). These results are for water released above 200 °C (to avoid terrestrial contamination<sup>3,7</sup>) and below 750 °C, the temperature by which most water has been released from Chainpur<sup>7</sup>. Comparable sized samples of local meteoric water transferred through the same apparatus and distilled water used for cooling when cutting the meteorite gave  $\delta D$  values typical of the latitude of the laboratory (-44 and -48% SMOW respectively).

The latter experiments are not a true procedural check because temperatures up to 750 °C were not used. Because the Cambridge laboratory uses deuterium for various labelling purposes, we aimed to demonstrate the validity of the preliminary results. Our experimental procedure is: for each water extraction we used a new quartz reaction vessel prebaked to >1,000 °C overnight on a line run at 200 °C. During water collection this vessel is valved off from the pumping system. Before sealing the extracted waters in a quartz takeoff finger (trapped by liquid N<sub>2</sub> for 2 h) for transfer to East Kilbride for isotopic measurements, non-condensable gases are pumped away by opening the valve to the high vacuum line for  $\sim 10$  s. There is no possibility of back trapping of water from the vacuum system during this pump-out because of the presence of a protecting liquid N<sub>2</sub> trap immediately next to the valve on the system side. During our experiments aliquots of a terrestrial biotite were processed alternately with the samples not as a measure of reproducibility, but as a contamination check.

All water samples were converted to hydrogen using the conventional hot uranium technique<sup>16</sup>. Isotopic analysis of hydrogen was performed on a VG Micromass 602 mass spectrometer using a reference of  $\delta D = -50\%$  relative to SMOW, produced from doubly distilled water and calibrated against the international standards V-SMOW and V-SLAP. The memory correction associated with reducing waters widely separated in  $\delta D$  was estimated from V-SMOW and V-SLAP analyses to be 1.5% and this has been applied to all meteorite data.

All our D/H data from unequilibrated ordinary chondrites are listed in Table 1. Bishunpur and Semarkona release water extremely enriched in deuterium. The biotite blanks run alternately with the samples indicate the results obtained are neither an analytical artefact nor the manifestation of deuterium contamination introduced in the Cambridge laboratory. The spread in biotite  $\delta D$  values is considerably greater than that of replicate total hydrogen extraction ( $\pm 2\%$ ,  $1\sigma$ ) and is attributable to incomplete yields for biotite using the experimental technique devised for meteorites.

Sample inhomogeneity is common on all scales in the least equilibrated ordinary chondrites<sup>14</sup> and may explain the dis-

Table 1 D/H data from unequilibrated ordinary chondrites

	Wt		$\delta D\%$

crepancy between the Bishunpur 3 result and those of the preliminary study<sup>15</sup>; Bishunpur 3 was obtained from an alternative source to the other two aliquots and the amount analysed was substantially less. The apparent inhomogeneity of Bishunpur may be significant and might indicate a sporadic occurrence of a minor very D enriched phase. We cannot explain the Krymka result which seems to suggest that the occurrence of anomalously heavy hydrogen is not simply a question of degree of unequilibration, although very inhomogeneous distribution of D rich phases cannot be ruled out. Water extracted from dark portions of the nominally H4 chondrite Weston, which has H3 type inclusions<sup>17</sup> and water present in veins of iddingsite<sup>18</sup>, does not exhibit an extreme D content. However, Weston has a compliment of solar wind gases<sup>19</sup> and any hydrogen present from the solar wind might be expected<sup>20,21</sup> to have a D/H of  $<3\times10^{-6}$  possibly counterbalancing a component enriched in D. The  $\delta D$  value obtained for Weston in this study (+16%) is greater than that of -100% reported by Robert et al.<sup>7</sup>

Our results are entirely for bulk unseparated meteorites. No attempt has been made to preconcentrate or selectively decompose the host phase of the water analysed. Alternative explanations for the Bishunpur and Semarkona data are either: (1) D enrichment is ubiquitous and all the hydrogen turning up in the water extracted has an isotope composition approaching that observed in certain Chainpur separates or (2) somewhere in these very unequilibrated chondrites is a phase of exceptionally high D content. In the case of Chainpur, stepwise heating and selection resulted in a  $\delta D$  increase from +200% for bulk material<sup>5</sup> to +4.400% for the 450-750 °C temperature cut from several chondrules<sup>7</sup>. If explanation (2) is correct for Bishunpur and Semarkona, a comparably successful future isolation study ought to reveal a truly extreme hydrogen isotopic composition. Either way, studies of the material separated from Bishunpur and Semarkona should help to identify the D-enriched host phases. A possible site for a D-rich phase surviving accretionary processes might be the opaque matrix reported by Huss et al.1 and thought to be the low temperature condensate of Larimer and Anders22

The problem of D-enriched molecules in primitive meteorites has been extensively discussed elsewhere  $^{23}$ . It might have been easier to accept deuterium depletions as the protosolar nebula is thought  $^{24}$  to have had a D/H ratio of  $2.5 \times 10^{-5}$  and unmetamorphosed meteorites could have been expected to have retained some original material. Geiss and Reeves  $^{23}$  concluded ion-molecule reactions at low temperatures to be the most likely means of concentrating deuterium, and inferred that the deuterated species in Chainpur and carbonaceous chondrites were remnants of dark interstellar clouds as first suggested as a possibility by Kolodny et al.  $^8$ . We must concur with this interpretation

as it is very unlikely that an elementary experiment such as ours has recognized the maximum deuterium enrichment in a Solar System material, and ion-molecule reactions seem to be the only feasible route to major fractionations. In dark clouds the greatest D enrichments (103-104 compared to SMOW) are observed for HCO, isocyanides and cyanides25, the latter being enriched by exchange reactions with CH2D+ or H2D+. The D enrichment in water in interstellar clouds is difficult to measure; Geiss and Reeves suggest a D content 50 times that of terrestrial water but recognize they are possibly an order of magnitude in error. If the heavy hydrogen in Bishunpur and Semarkona is confined to a specific fraction as seems to be the case in Chainpur7, and indeed exists as water, it is not inconceivable that a practically 'pure' sample of interstellar water has survived into the Solar System. It could be just as important to recognize that the heavy hydrogen is associated with some polymeric carbonaceous phase which condensed from deuterium enriched species. Unequilibrated ordinary chondrites have up to 0.5 wt% 5, which as yet is substantially uncharacterized.

We thank Drs S. O. Agrell, R. Hutchison and R. S. Clark for samples, Dr P. J. Hamilton and Miss M. M. Grady for help with sample preparation, the SERC and NERC for financial assistance, and Dr R. S. Harmon and Professor H. W. Wilson for facilities and support respectively.

The composition of the atmosphere is influenced both directly and indirectly by biological activity. Evidence is presented here to suggest that nitrification in soil is a potentially significant source of both NO and N2O. Between 0.3 and 10% of the ammonium oxidized by cultures of the soil bacterium Nitrosomonas europaea is converted to these gases. The global source for NO associated with nitrification could be as large as 15×10<sup>4</sup> tonnes N yr<sup>-1</sup>, with a source for N<sub>2</sub>O of 5-10×10<sup>4</sup> tonnes Nyr-1. Nitric oxide has a key role in tropospheric chemistry, participating in a complex set of reactions regulating OH and O<sub>1</sub> (refs 1.2). Nitrous oxide is a dominant source of stratospheric NO (refs 3-5) and has a significant infinence on climate'.

Table 1 Relative rates for NO, N2O and NO2 production by cultures of Nitrosomonas europaea

Oxygen concentration (% v/v)	$\frac{NO/N_2O}{\binom{mol\ N}{mol\ N}}$	$ \frac{N_2O/NO_2^-}{\left(\% \frac{\text{mol } N}{\text{mol } N}\right)} $	$\frac{NO/NO_{2}^{-}}{\left(\% \frac{\text{mol } N}{\text{mol } N}\right)}$	No. of replicates
0.5	$5.1 \pm 3$	$0.9 \pm 0.3$ *	$3.8 \pm 1.2$	2
0.5		$2.5 \pm 0.1$		3
1.0		$0.9 \pm 0.1$	-	3
1.3	1.4†		$1.25 \pm 0.2$	2
5.0		$0.15 \pm 0.02$		3
10.0		$0.16 \pm 0.01$	*****	3
21.0		· —	$0.13 \pm 0.1$	2
21.0	$1.15 \pm 0.15$	$0.47 \pm 0.13$	$0.51 \pm 0.1$	2

Ratios are given as mol % for N2O and NO relative to NO2, but as mol/mol for NO relative to N2O.

\* Production of N2O increased relative to NO2 in this run, from 0.5% initially to 1-2% at the end.

† Estimated from  $N_2O/NO_2^-$  at 1%  $O_2$  and  $NO/NO_2^-$  at 1.3%  $O_2$ .

Enzyme preparations derived from nitrifying bacteria are known to produce trace quantities of NO and N2O (refs 7,8) and release of these gases has also been observed from dense cultures. Goreau et al. 10 investigated rates for production of N<sub>2</sub>O by marine nitrifying bacteria, grown under a range of oxygen concentrations from 0.5 to 20%. The yield for N<sub>2</sub>O, defined as the ratio of N<sub>2</sub>O produced relative to NH<sup>+</sup> oxidized, was about 0.003 mol N N<sub>2</sub>O per mol NH<sub>4</sub> at O<sub>2</sub> concentrations above 2%. The yield rose sharply at lower concentrations of O2, reaching 0.1 for an O<sub>2</sub> concentration of 0.5%. The investigation of Goreau et al.<sup>10</sup> is extended here with studies of a soil nitrifier, N. europaea.

Cells from actively growing cultures were inoculated into 500-ml flasks containing 300 ml of aqueous growth medium<sup>1</sup> with 25 mmol NH<sub>4</sub>. The initial density of cells was  $\sim 10^6$  cm<sup>-3</sup>. The medium was stirred continuously, purged by a stream of gas consisting of N<sub>2</sub> and CO<sub>2</sub> (300 p.p.m.), with predetermined concentrations of O<sub>2</sub>. Temperature was maintained at 25 °C, with pH buffered at 7.5.

Flushing time of the flasks was fixed in the range 4-10 min, sufficient to ensure equilibrium between liquid medium and gaseous headspace. Medium was sampled periodically and analysed for NO<sub>2</sub> and cell numbers (see ref. 10). Concentrations of nitrous oxide and oxygen in the outflow were measured using gas chromatography with electron capture and thermal conductivity detection respectively<sup>11</sup>. Nitric oxide was measured using a chemiluminescence detector, with procedures designed to eliminate interference from other gases 12. Production of N<sub>2</sub>O was measured at  $O_2$  levels of 20, 10, 5, 1 and 0.5%. Production of NO was determined for  $O_2$  concentrations of 20, 1.3 and 0.5%.

Experimental results are presented in Fig. 1 and Table 1. Production rates for N<sub>2</sub>O, NO and NO<sub>2</sub> were closely parallel, as observed previously <sup>10</sup> for NO<sub>2</sub> and N<sub>2</sub>O. Cultures produced N<sub>2</sub>O and NO with uniform ratios relative to NO<sub>2</sub> at O<sub>2</sub> levels above 1% (Fig. 1a, c). Replicate flasks gave consistent results, with variability largest at low O2. The rate for evolution of NO correlated strongly with that for N<sub>2</sub>O (see Fig. 1d). Measurements of cell numbers showed that cell division did not occur in cultures with  $O_2$  equal to 20%, and production of  $NO_2^-$ , NO and  $N_2O$  were constant with time in these experiments (see Fig. 1a). Active cell division occurred in all other experiments, with doubling times of  $0.8 \pm 0.2$  days. Yields for NO and N<sub>2</sub>O were constant relative to NO<sub>2</sub>, independent of whether or not cells were dividing. An exception occurred at 0.5% O2, where the yield for N<sub>2</sub>O increased with time even though the yield for NO remained constant.

Results for NO and N<sub>2</sub>O are given in Table 1 at various oxygen concentrations. Yields for both gases rose markedly at O<sub>2</sub> concentrations below 2%. The ratio of NO production relative to N2O also rose as O2 decreased, with a median value of ~1.5 mol N NO per mol N N2O.

Two experiments were performed which indicated a metabolic origin for the bulk of NO observed in the present work. First, sterile culture medium was spiked with  $NO_2^-$  to a concentration above that in the active cultures. A small transient pulse of NO was observed but emission terminated within minutes. Second, an actively growing culture of *N. europaea* was killed by addition of 1 ml saturated solution of a potent respiratory inhibitor,  $HgCl_2$ . The NO signal declined promptly, falling within 50 min to 10% of the value observed before addition of  $HgCl_2$ . Decay of NO followed the time course expected from flushing of the experimental apparatus, with negligible (<10%) abiotic production. The behaviour was similar to that observed earlier for  $N_2O$  (ref. 10).

The concentration, C (cm<sup>-3</sup>), of NO or N<sub>2</sub>O measured at the outlet of the apparatus may be written in the form

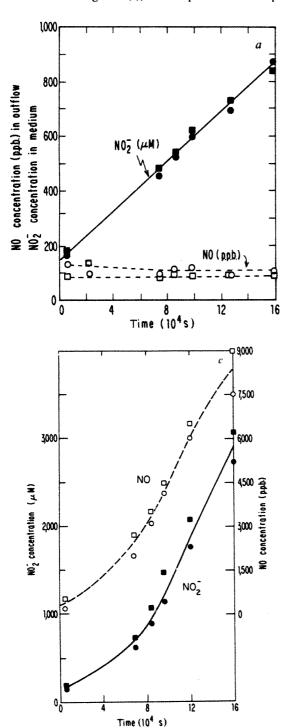

$$C = Pt/(1 + Lt)$$

where t is the flushing time (s), P is the production rate per unit

volume of the apparatus (cm<sup>-3</sup>s<sup>-1</sup>) and L is a loss frequency (s<sup>-1</sup>) introduced to account for possible loss in the medium, in the head space or on the walls of the apparatus. Figure 2 shows a plot of CV/t, the mass flux from the apparatus, as a function of t (where V is the volume of the apparatus, t = V/(flow rate)). This quantity should be independent of t for  $Lt \ll 1$  and should vary as  $t^{-1}$  for  $Lt \gg 1$ . The results in Fig. 2 suggest that losses of NO are negligible in the present system, that  $L^{-1} \gg 4$  min. Loss of N<sub>2</sub>O is similarly small<sup>10</sup>.

Nitrification is thought to provide a major source for atmosphere.

Nitrification is thought to provide a major source for atmospheric  $N_2O$  (refs 10, 13, 14). The global source of  $N_2O$ , known from considerations of atmospheric chemistry<sup>15</sup>, is  $10\times10^6$  tonnes N yr<sup>-1</sup>. If we assume that this source is associated primarily with nitrification and adopt relative production rates indicated in Table 1, we may estimate that the corresponding source of NO could be as large as  $15\times10^6$  tonnes N yr<sup>-1</sup>. There may be sources of  $N_2O$  in addition to nitrification, for example, denitrification<sup>16</sup> and lightning<sup>17</sup>. Our estimate for the

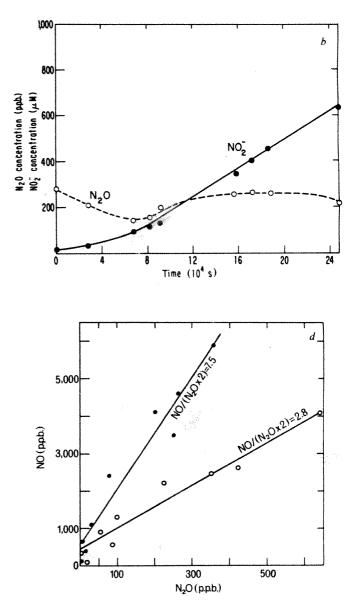

Fig. 1 Measured concentrations of NO,  $N_2O$  and  $NO_2^-$  in selected experiments with N. europeaea at different oxygen tensions. Gas concentrations were measured in the outflow of the apparatus and are proportional to the production rates by the cultures. Nitrite accumulated in the medium and hence measured concentrations must be differentiated to obtain production rates. a, NO and  $NO_2^-$  at 20% O<sub>2</sub>, squares and circles represent replicate cultures; b,  $N_2O$  and  $NO_2^-$  at 1% O<sub>2</sub>; c, NO and  $NO_2^-$  at 1.3% O<sub>2</sub>; d,  $N_2O$  and NO at 0.5% O<sub>2</sub>.

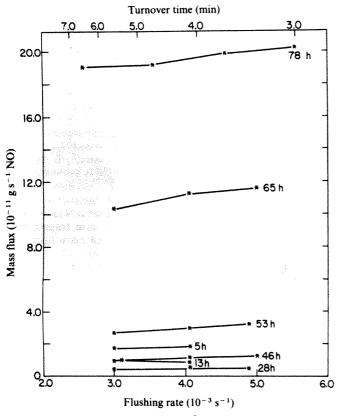

Fig. 2 The mass flux of NO (g NO s<sup>-1</sup>) is plotted as a function of gas flow rate through the apparatus, at various times after inoculation. The flushing rate is defined as (flow rate)/(head space volume). For 0-46 h, purge gas contained 20% O2, the cells did not divide and NO was produced at low rate. Reduction of O2 to 0.5% induced almost immediate increase in production of NO, NO2 and bacterial cells. At both oxygen levels the mass flux seems to be independent of flow rate, implying negligible loss of NO in the apparatus (see text).

nitrification source of NO would be lowered accordingly. Also, NO could be removed by heterogeneous processes before release to the atmosphere (see ref. 12).

Galbally and Roy<sup>18</sup> observed fluxes of NO with an average value of  $2 \times 10^{-12}$  kg N m<sup>-2</sup>s<sup>-1</sup> from soils in Australia. They estimated a corresponding global source of 10×10<sup>6</sup> tonnes N yr<sup>-1</sup>, similar to the value derived here. Our data are consistent with the view that nitrifying bacteria could produce a substantial fraction of the NO observed by Galbally and Roy18, although there could also be production by dentrification 19 or by abiotic reactions involving NO<sub>2</sub> (refs 20,21).

The source of NO derived here is similar in magnitude to production by combustion<sup>2,22</sup>, photooxidation of NH<sub>3</sub> (ref. 23), decomposition of stratospheric N<sub>2</sub>O (refs 15,22) and lightning (ref. 24). The lifetime of fixed nitrogen species in the atmosphere is rather brief<sup>2,25</sup>. It follows that nitrification in soils could exercise a major influence on the NO, budget of the troposphere, with particular significance for regions remote from

### Structure sensitivity in the iron single-crystal catalysed synthesis of ammonia

N. D. Spencer, R. C. Schoonmaker\* & G. A. Somorjai

Materials and Molecular Research Division. Lawrence Berkeley Laboratory, and Department of Chemistry, University of California, Berkeley, California 94720, USA

There have been many investigations of the kinetics of the iron-catalysed synthesis of ammonia and the details of the mechanism of its reaction<sup>1-3</sup>. However, we report here the first direct and, therefore, unambiguous measurement of the surface structure sensitivity of the iron-catalysed ammonia synthesis reaction using the (111), (100) and (110) crystal faces of iron and operating at pressures approaching those used industrially (20 atmospheres). The Fe(111) face was found to be the most active, the activity ratio being 418:25:1 for the Fe(111), Fe(100) and Fe(110) planes. We have also observed the formation of a strongly bound nitrogen species after the reaction, in the presence of which ammonia continues to be produced.

The apparatus<sup>4</sup> consisted of a stainless steel ultrahigh vacuum chamber equipped with a four-grid retarding field analyser for Auger and low-energy electron diffraction measurements of the surface composition and structure, a residual gas analyser, an ion gun for specimen cleaning and a high-pressure cell connected to an external loop. Reactant and product gases at a total pressure of 20 atmospheres were continuously circulated over the heated iron crystal specimen by a positive displacement pump; samples, periodically withdrawn using a gas chromatograph type sampling valve, were passed by a nitrogen carrier through a photoionization detector to determine the amount of ammonia in the loop. Ammonia was the only species present which could be detected by the photoionization detector obviating the need for a separating column.

Circular iron specimens with crystal faces (111), (110) and (100) were spark-cut from a high-purity (4N) single-crystal rod and diamond polished, the final dimensions being ~6 mm diameter and 1 mm thickness. Sulphur and carbon were found to be the principal contaminants after this procedure, but could be removed by several days of heating at 800°C in 1 atmosphere of hydrogen, followed by many cycles of argon ion bombardment and annealing at 700 °C. To minimize the catalysis occurring on ill-defined iron surfaces, platinum foil was spot-welded to the rough edges of the specimens.

Results of measurement of structure sensitivity are shown in Table 1 from which it can be seen that the (111) surface of iron catalyses the synthesis of ammonia from hydrogen and nitrogen at least 418 times faster than the ordered (110) surface and 16 times faster than the ordered (100) surface. Our result is consistent with the low pressure chemisorption studies of Ertl and co-workers2 where it was reported that the rate of dissociative chemisorption of nitrogen is greatest on the (111) plane of iron

<sup>\*</sup> Permanent address: Department of Chemistry, Oberlin College, Oberlin, Ohio 44074, USA.

Table 1 Surface structure sensitivity of ammonia synthesis

Catalyst surface	Area (cm²)	Rate* (mols NH <sub>3</sub> cm <sup>-2</sup> s <sup>-1</sup> )
Fe(111)	0.63	$4.6 \times 10^{-8}$
Fe(100), ordered	0.80	$2.8 \times 10^{-9}$
Fe(110), ordered	0.57	0†
Fe(100), disordered‡	0.80	$4.5 \times 10^{-9}$
Fe(110), disordered‡	0.57	$9.7 \times 10^{-10}$

- \* Total pressure, 20 atm.;  $P_{\rm H_2}/P_{\rm N_2}=3/1$ ; temperature = 798 K. † Detection limit ~1.1×10<sup>10</sup> mol NH<sub>3</sub> cm<sup>-2</sup> s<sup>-1</sup>. ‡ Argon ion bombardment  $(1.5\times10^{-5})$  A cm<sup>-2</sup> for 10 min at 500 V).

and least on the (110) plane, and also with previous suggestions<sup>1-3,5</sup> that this step is rate-determining in the ammonia synthesis reaction.

The (111) plane of iron contains both seven-coordinated  $(C_7)$ and four-coordinated (C<sub>4</sub>) atoms, whereas the (110) and (100) planes contain only six-coordinated (C<sub>6</sub>) and C<sub>4</sub> atoms, respectively. The large variation in rates of ammonia synthesis on the various planes (Table 1) and the anomalously high catalytic activity that we have also detected on the (110) and (100) planes when deliberately disordered by ion bombardment, support the proposals of Brill<sup>6</sup> and others<sup>3,7</sup> regarding the importance of clusters and C7 iron atoms as components of the active site on the catalyst surface.

Although bulk nitrides of iron are thermodynamically unstable in the conditions of these experiments, we have observed the existence of a long-lived, strongly-bound nitrogen species after the synthesis reaction on both Fe(111) and Fe(100) crystal faces in the presence of which ammonia continued to be produced at an undiminished rate. The catalytic significance of this surprising observation has yet to be determined.

## An oceanic carbonatite volcano on Santiago, Cape Verde Islands

L. Celestino Silva\*, M. J. Le Bas† & A. H. F. Robertson‡

\* Junta de Investigações Científica do Ultramar, Laboratório de Estudos Petrológicos e Paleontológicos, Lisbon 1000, Portugal † Department of Geology, The University, Leicester LE1 7RH, UK ‡ Grant Institute of Geology, University of Edinburgh, Edinburgh EH9 3JW, UK

Carbonatite volcanoes are rare, the only active one being at Oldoinyo Lengai in northern Tanzania<sup>1</sup> although a few dead volcanic centres with recognizable carbonatitic extrusive materials are known elsewhere in Africa2-6 and one in Germany<sup>7</sup>. During an expedition in 1980 to the Cape Verde Islands, in the Central Atlantic Ocean 500 km west of Senegal, the eroded remains of a carbonatite volcano were discovered on the island of Santiago just north of Tarrafal at Arruela (Fig. 1). This, the first example of an oceanic carbonatitic volcanic pyroclastic structure, shows typical carbonatite mineralogy and geochemistry, and demonstrates that carbonatite magmas can be generated in the oceanic lithosphere as well as in the continents.

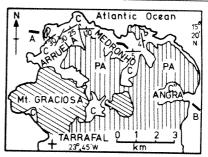

Fig. 1 Geological sketch map of northern Santiago (after Serralheiro<sup>9</sup>). S, Phonolite (youngest lavas); III, Pliocene plateau basalts of Pico da Antonia Formation (PA); ©, intrusive, pyroclastic and epiclastic carbonatitic lithic tuffs. C" is explained in Fig. 2.

An oceanic character for the Cape Verde Islands region seems the most probable, although the possibility of a fragment of continental crust existing in the area cannot be totally discounted. However, the position of these volcanic islands some 400 km west of the westernmost parts of the West African continental shelf astride the Mesozoic oceanic geomagnetic anomalies<sup>8,9</sup>, the mid-oceanic ridge basalt geochemical character of the pillow basalts of the region 10 and the fact that the islands have apparently grown from the oceanic floor, leave little doubt as to their oceanic setting.

Carbonatitic magmatism has been said to characterize intraplate continental crust<sup>5</sup>, but this discovery of a carbonatite volcano and therefore of undoubted carbonatite magmatism demonstrates that such magmas can form in oceanic lithosphere. The intrusive carbonatitic equivalents, together with ijolites, on most of the other Cape Verde Islands (and some of the Canary Islands) suggest that intraplate oceanic carbonatitic magmatism is not rare; in fact it is commonplace in all oceanic islands with long geological histories so far investigated.

Only the basal wreck of the former pyroclastic cone on Santiago remains (Fig. 2), and it comprises carbonatitic and nephelinitic subaerial tuffs pierced by carbonatite and nephelinite dykes and veins. In every petrological feature, apart from the absence of natrocarbonatite lava, the structure and petrology are exactly similar to those at Oldoinyo Lengai volcano. The greater part of the cone seems to have been planed off by erosion, and much of the material redeposited as shallow marine epiclastic carbonatitic conglomerates, siltstones and calcilutites. These are covered by bioclastic calcarenites and plateau basalts.

Beneath the erosion level, exposures in the western sea-cliffs reveal great thicknesses of massive pale-coloured carbonatecemented agglomerates, ashes and tuffs which carry an assortment of coarse-grained, fine, dark, light-coloured, big (1m) and small blocks. Elsewhere the rocks are better bedded with occasional large-scale low-angled cross-bedding, generally dipping seawards. They and the associated agglomerates are calcareous, and all abound with biotite flakes and lithic fragments including apatite-sövite, ijolite, apatite-pyroxenite and olivine-poor nephelinite.

The unique carbonatitic character of the sub-aerial ochrecoloured tuffs which make up the bulk of this former volcanic structure, is not immediately apparent in the field, and had not been recognized by previous workers<sup>11,12</sup>. The microscope reveals that the tuffs are 95% or more of rounded grains of calcite crystallites, each grain usually having a brown-stained core. This texture is similar to that seen in carbonatitic tuffs in East Africa. Some horizons include lapillistone containing spherical lava tears with quench textures identical to those described recently from Kaiserstuhl<sup>7</sup>. Interleaved with the carbonatitic tuffs and agglomerates are large masses of pale grey-green unbedded clays up to 5 m thick. As the clays carry abundant ijolite and nephelinite clasts, these clays are interpreted as altered nephelinitic tuffs and ashes. The assemblage is identical to that at Oldoinyo Lengai<sup>1</sup>, and it all points to a mainly pyroclastic mechanism of eruption with much of the lava being emitted as droplets perhaps during nuée ardente eruptions.

Fig. 2 Cross-section along line A-B in Fig. 1 showing the eroded remains of the carbonatitic and pyroclastic volcanic cone (CA) penetrated carbonatite adventive plugs (C') and dykes, unconformably (shown schematically) overlain by

carbonatitic epiclastic beds (CB) and calcarenites (dotted); above are Pico da Antonia basalts (PA). At Angra is a carbonatite-ijolite-syenite-breccia plug (C") which intrudes basalt pillow lavas (P), and is overlain unconformably by PA basalts.

Penetrating the tuffs are a great variety of dykes and plugs. Several tuff dykes, 0.1-3.0 m wide, carry abundant ijolite fragments, some as cored autoliths with nephelinitic coatings. Other dykes which run in all directions are often only 0.2-0.5 m wide and include olivine-poor nephelinites (with nepheline, aegirineaugite, melanite-garnet, perovskite, apatite, analcime and some phlogopite) and carbonatites. One carbonatite dyke 0.2 m wide made up entirely of carbonate revealed, under the microscope, discontinuous pieces of convoluted flow texture of deformed ovoids, and appears to represent a flowed and fragmented carbonatitic pumice which must have been emplaced in a fissure not far below a point of extrusion.

Intrusive plugs, one up to 15 m diameter<sup>12</sup>, of flow-banded dolomitic carbonatite brecciate their way through the bedded tuffs. Also penetrating the tuffs are vertical, roughly circular haematitic patches 1-3 m across, apparently representing paths of fumarolic fluids passing upwards through the ochreous tuffs.

An 87Sr/86Sr determination of the Arruela plug carbonatite (at the Université de Clermont-Ferrand) gave 0.7040 which is close to earlier determinations of other Cape Verde and Canary Island carbonatites<sup>13,14</sup>. This confirms the igneous character of these carbonatite plugs. Preliminary X-ray fluorescence analysis (H. Furnes at Bergen University) for the trace element content of the carbonatites (Table 1) shows high contents of the incompatible elements which is typical of true carbonatites<sup>6</sup>. They are further noteworthy for the unusually high Zn content and the strong rare-earth enrichment in the intrusive carbonatites

A period of sub-aerial followed by marine erosion seems to have decapitated this pyroclastic volcano, leaving it buried beneath 10-100 m of epiclastic sediments largely composed of detritus derived from the destruction of the volcano. Conglomerates and grits fill hollows in the underlying tuffs. The dips are variable and usually low (0°-20°) except where now seen in some slipped sections along the cliffs. Some beds are well stratified fine siltstones, some with graded bedding, others with cross-lamination. There are moulds of large marine gastropods. In further contrast to the volcanic tuffs below, these beds are rarely cut by dykes and then only by basaltic ones, and are quite well sorted. Clasts of ijolite, pyroxenite and nephelinite up to 0.1 m across are common and biotite flakes abound. Under the microscope these epiclastic siltstones and grits are seen to be composed of abundant grains of carbonatite, recognizably the

same as those in the underlying tuffs, and with detrital apatite, aegirine, garnet, perovskite and chert.

In places along the erosional unconformity with the overlying Pico da Antonia Formation alkali basalts, these lenticular epiclastic sediments are strongly reddened. There is also a concentration of ijolite, nephelinite, basalt and red carbonatite clasts in the conglomerate marking this unconformity. In the Ponta Moreia area, marine bioclastic calcarenites, a few metres thick and containing oncolites, usually lie immediately under the basalts.

It is estimated that the exposed area of the carbonatitic pyroclastic volcano remnant exceeds 10 km<sup>2</sup>, and any envisaged reconstruction of a volcano on this site produces a structure very similar to that at Oldoinyo Lengai in northern Tanzania.

The main conduit of the volcano is unknown. The vent might be sited centrally in the northern part of Santiago and would then be hidden beneath the later basalt and phonolite lavas. But it is more likely that the intrusive ijolites, carbonatites and breccias at Angra, presently standing nearly 200 m above sea level and penetrating old pillow lavas, mark the site of the vent-plug. The age of the volcano is not known except that it is older than the Pico da Antonia basalts which previous workers estimate are Pliocene-Miocene<sup>12</sup>. K-Ar dating<sup>15</sup> gave 4-5 Myr for the basalts, and 8.5 and 9.8 Myr for intrusive carbonatites elsewhere in Santiago.

Carbonatitic volcanism must therefore no longer be considered as restricted to continental regions. This oceanic intraplate occurrence demonstrates that carbonatite magma can form in suboceanic as well as subcontinental lithospheric mantle. A further implication would seem to be that whilst small ocean islands such as St Helena represent small developments of alkaline magmatism, the bigger archipelagos such as the Cape Verdes seem to be the result of more extensive alkaline magmatism which can produce more extreme alkaline compositions. This probably reflects greater mantle metasomatism in the source regions. Mantle heterogeneity has been widely advocated recently 16, but such extremes beneath oceans have not been suggested before.

We thank the other members of the expedition: H. Furnes, M. J. Norry, C. J. Stillman and J. Zielonka, and the Cape Verde Government, particularly to Eng. H. Soares and Dr Mota Gomes of the Ministério do Desenvolvimento Rural, and Eng. M. Monteiro of the Ministério da Coordenação Económica, for help, hospitality and transport. ## Platinum and palladium minerals in upper mantle-derived lherzolites

#### Reid R. Keays & David K. B. Sewell

Department of Geology, University of Melbourne, Parkville, Victoria 3052, Australia

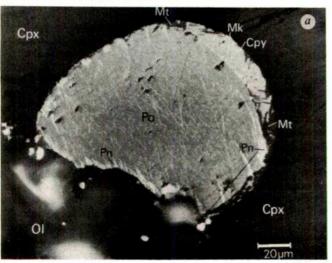

#### Roger H. Mitchell

Department of Geology, Lakehead University, Thunder Bay, Ontario, Canada P7B 5E1

Spinel Iherzolite xenoliths in basanites from the Newer Volcanics of Western Victoria, Australia contain sulphide inclusions along grain boundaries and within fractures in the silicates. The inclusions are complex intergrowths of pentlandite, pyrrhotite and chalcopyrite formed by the breakdown of Fe-Ni monosulphide solid solutions. During this process discrete grains of a platinum sulphide and a palladium stannide were exsolved from the pentlandite. We show here that this is the first evidence for sulphide fluids rich in platinum group

elements in the upper mantle.

During an investigation of the distribution of Au, Pd and Ir in mantle-derived spinel lherzolites from basanites of the Newer Volcanics of Western Victoria, Australia2, it was discovered that the bulk (60-80%) of these metals are not held in solid solution in any of the major silicate or oxide phases but are concentrated in the intergranular regions1. The intergranular phases consist of serpentines, magnetite, goethite and sulphides which are located along grain boundaries and within fractures in the silicates. Textural evidence indicates that the sulphides have been introduced into the xenoliths along these microfractures. The sulphides were not introduced into the xenoliths during transport as the host basanite lacks such materials, is undersaturated in sulphur and is poor in Au, Ir, Pd1. We consider that the sulphides were added to the xenoliths in the mantle and represent an immiscible sulphide melt formed during a partial melting episode before that which generated the host lava which merely transports the xenoliths to the Earth's surface<sup>1</sup>. In view of the chalcophilic properties of the platinum group elements<sup>3</sup>, it was proposed that these sulphides might be the major host of the intergranular platinum group elements1. To investigate this

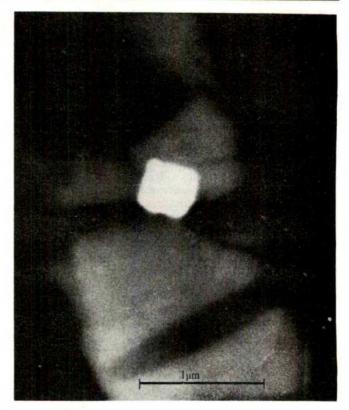

Fig. 2 Back-scattered eletron photograph obtained using a Robinson detector coupled to a scanning electron microscope. The euhedral phase showing strong atomic number contrast (white) is platinum sulphide set in a pentlandite host (grey). Black areas are cleavages or fractures.

hypothesis we examined the sulphides using scanning electron microscopy and discovered discrete grains of platinum group minerals.

Figure 1a shows a typical ovoid sulphide inclusion and illustrates the complexity of the sulphide intergrowths. The bulk of the globule consists of pyrrhotite with exsolved flames of pentalandite, this assemblage being mantled by chalcopyrite containing exsolved mackinawite. The chalcopyrite is replaced along cleavages by magnetite.

Figure 1b shows another sulphide globule consisting of pentlandite which has been replaced by magnetite. Within this

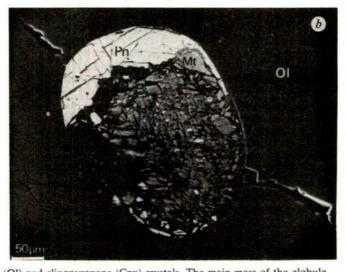

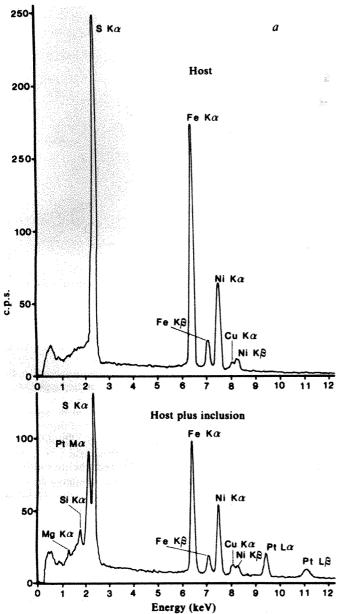

Fig. 1 a, Composite sulphide globule at the contact between olivine (OI) and clinopyroxene (Cpx) crystals. The main mass of the globule consists of pyrrhotite (Po) containing exsolved pentlandite (Pn). This is mantled by chalcopyrite (Cpy). Thin lamellae of mackinawite (Mk) occur within the chalocopyrite which is also replaced along cleavages by magnetite (Mt). This photomicrograph illustrates the incipient replacement of sulphides by oxides. Reflected light photograph of polished thin section. b, Sulphide globule located within a fracture in olivine consisting of pentlandite and magnetite. This was originally an entire sulphide globule similar to that shown in a. The black areas mark plucked sulphide or oxide. Reflected light photograph of polished section

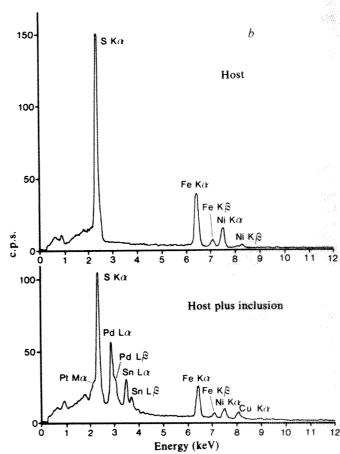

Fig. 3 X-ray energy dispersive spectra of host pentlandite (upper) and of host plus inclusion (lower). a, Inclusion is platinum sulphide;
b, inclusion is palladium stannide.

globule we located the discrete Pt-mineral described below. The original mineralogy of the globule before magnetite replacement was probably similar to that of the inclusion shown in Fig. 1a.

Platinum group minerals were located using a Robinson back-scattered electron detector coupled to a scanning electron microscope<sup>4</sup>. This type of imaging enhances the atomic number constrast for back-scattered electrons from matrices of differing average atomic number and is ideally suited for the detection of platinum group minerals of high atomic number in a Fe-Ni-sulphide matrix. Figure 2 illustrates the excellent atomic number contrast exhibited between a Pt-mineral and its pentlandite host.

The inclusion is too small  $(0.5 \,\mu\text{m})$  to extract for X-ray diffraction identification and for quantitative in situ electron microprobe analysis, as the excitation area produced by the electron beam is larger than the inclusion, resulting in excitation of the host. Figure 3a thus shows X-ray spectra of the pentlandite host and of the host plus inclusion to demonstrate that the inclusion is a discrete phase. The spectrum of the host plus inclusion contains strong Pt X-ray lines which are lacking in the host alone. The presence of minor peaks attributable to Mg and Si indicates fluorescence of intergranular serpentine or of the olivine which hosts the sulphide inclusion. The mineral lacks As, Sb, Bi, Pd and Sn, any S present is masked by the S peaks of the

pentlandite. From this qualitative analysis we believe the inclusion to be a platinum sulphide, probably cooperite (PtS).

Examination of other sulphide globules resulted in the discovery of several anhedral grains of a palladium mineral in a pentlandite host. Figure 3b shows X-ray spectra for the host and the inclusion plus host. The presence of strong X-ray lines of Pd and Sn together with only a weak Pt line and the absence of As, Sb, Bi indicates that the mineral is a palladium stannide. Unfortunately, we were not able to analyse this phase quantitatively. The mineral could possibly be paolovite  $(Pd_2Sn)$ , atokite  $(Pd_2Sn)$  or stannopalladinite  $(\alpha-Pd_3Sn_2)$ .

Sulphide globules containing complex Cu-Ni-Fe sulphide intergrowths similar to those described above have been noted to occur in spinel lherzolites and eclogites<sup>5-7</sup>. However, to our knowledge this is the first occurrence of discrete Pt and Pd minerals in such an upper mantle xenolithic paragenesis.

Studies of magmatic nickel-platinum group element ore deposits such as those associated with the Sudbury and Bushveld intrusions coupled with experimental studies of Cu-Ni-Fe sulphide phase quilibria have demonstrated that the precursors to the pentlandite-pyrrhotite-chalcopyrite intergrowths are Fe-Ni-monosulphide solid solutions which crystallized from a sulphide liquid initially formed by liquid immiscibility from a sulphur saturated basic silicate melt<sup>8,9</sup>. The originally homogeneous monosulphide undergoes a variety of subsolidus

breakdown reactions as it cools from magmatic temperatures (~1,000°C). For example, pentlandite only becomes stable below 610°C and the pentlandite-pyrrhotite intergrowths probably develop below 300°C (ref. 6). Platinum group minerals in such parageneses occur as discrete grains in sulphide host and exhibit textural relations similar to those observed in the spinel lherzolites. Cabri and Laflamme<sup>10</sup> proposed that most of the platinum group minerals in such ores must also have originated by sub-solidus exsolution from a platinum group element-rich sulphide. Accordingly we believe that the discrete Pt and Pd minerals noted above have exsolved from pentlandite at low temperatures, the pentlandite itself having previously formed by the low temperature breakdown of Fe-Ni monosulphide solid solution. The initial sulphide liquid was introduced into the lherzolite within the mantle and in those conditions would have crystallized to a homogeneous platinum group element-rich monosulphide solid solution. Sub solidus breakdown probably occurred after incorporation into the transporting magma during cooling of the lava subsequent to eruption.

Speculation concerning the source of the sulphide liquids is beyond the scope of this note, but the above observations demonstrate that platinum group element-rich sulphide liquids are present in the upper mantle. This conclusion has important consequences with regard to the geochemistry of the platinum metals in general and in particular to their distribution between the Earth's core and mantle and to the possibilities of the addition of magmatic sulphide liquids to lherzolite within the upper mantle.

## Cross-polarization <sup>13</sup>C-NMR spectroscopy with 'magic angle' spinning characterizes organic matter in whole soils

Michael A. Wilson\*, Ronald J. Pugmire\*, Kurt W. Zilm†, Kuan M. Goh‡, Sammy Heng‡ & David M. Grant§

The limitations of <sup>13</sup>C cross-polarization (CP) NMR spectroscopy with 'magic angle' spinning to characterize the organic matter in whole soils have recently been discussed1: resonances from rotor materials and from spinning sidebands prevented a complete analysis of the types and forms of carbon in whole soils. We now report experiments in which these problems have been overcome. The results show that carboxylic, aromatic, acetal, alkoxy and alkyl carbon are present in soils and they allow approximate estimates of various carbon types to be made without previous extraction from the soil.

Permanent address: CSIRO Division of Fossil Fuels, PO Box 136, North Ryde, Australia 2113.

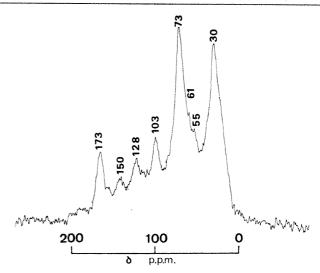

Fig. 1 CP-MASS spectrum of Mapourika soil. Spectrum was obtained with a contact time of 1 ms and a recycle time of 0.3 s; 10<sup>5</sup> transients were collected.

There have been no adequate techniques for characterizing soil organic compounds in the solid state. Moreover, the limited solubility of these materials, even in strongly alkaline media, makes studies on extractable material of limited applicability. CP-13C-NMR spectroscopy could provide qualitative information about the fraction of carbon which is aromatic, the aromaticity  $(f_a)$  of whole soils<sup>2</sup>, but detailed information on the chemical structure of in situ organic matter is hidden because the linewidths of CP-13C-NMR signals in solids are of the order of 200 p.p.m. due to chemical shift anisotropy. Spinning the sample at an angle of 54° 44' to the applied field (the 'magic angle' sample spinning technique, MASS) reduces linewidths to a magnitude comparable with that obtained for species in solution. Unfortunately, the low carbon content of soils precludes the use of conventional rotor materials (usually deuteopolymethylmethacrylate) for obtaining spectra of whole soils<sup>1,2</sup> have used a rotor consisting of a barrel of boron nitride with a seat of Kel F (K.W.Z., unpublished work), and sufficient spinning speeds (~3.5 kHz at 25.1 MHz <sup>13</sup>C frequency) to remove sidebands. Some characteristics of the soils used are given in Table 1 (more detailed information is available elsewhere<sup>4-7</sup>). Five soils have been investigated in this initial study, two young soils (age <400 yr) and three older soils (age >11,000 yr). Two

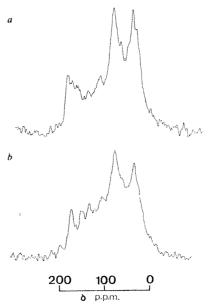

Fig. 2 CP-MASS spectra of a, Franz X and b, Ikamatu soil. Spectra were collected in similar conditions as Mapourika soil.

Table 1 Characteristics of soils								
Soil	Horizon	Age (yr)	pH (1:2.5 with H <sub>2</sub> O)	C (%)	Parent material	New Zealand classification

of the soils (Hokitika and Ikamatu) form part of the Reefton chronosequence and two others (Mapourika and Franz X) are from the Franz Josef chronosequence. Both chronosequences are in the South Island, New Zealand.

Figure 1 shows the CP-MASS- $^{13}$ C-NMR spectrum of Mapourika soil.  $^{13}$ C resonances can be assigned if it is assumed that the isotopic chemical shifts ( $\delta$ ) in such solids are not significantly different (that is  $\pm 2$ -3 p.p.m.) from those in solution. The spectrum can be divided into five regions:  $\delta$  10–50 p.p.m. (alkyl carbon),  $\delta$  50–100 p.p.m. (O-alkyl carbon),  $\delta$  100–110 p.p.m. (acetyl carbon),  $\delta$  110–160 p.p.m. (alkene and aromatic carbon) and  $\delta$  160–200 p.pm. (carbonyl carbon). The aromatic region consists of two distinct groups of resonances centred around  $\delta$  128 p.p.m. and 150 p.p.m. The latter most probably arises largely from aromatic carbons next to oxygen (phenols and furans). The former is protonated carbon plus substituted carbons of aryl carboxylic acids.

The proportions of various carbon types present in the soil determined by integrating the six regions of the spectrum in Fig. 1 are given in Table 2. These values are only approximate estimates for several reasons. First, because resonances from the various carbon types are not fully resolved, it is not possible to integrate the spectra with great accuracy. Second, it is not possible to differentiate between carbons which may be unusually shifted upfield or downfield from their respective common chemical shifts. Third and most important, the cross-polarization process does not necessarily give quantitative data. It must be established that the proton population relaxes with a uniform time constant  $(T_{1p})$  and that sufficient time delays between repeating pulse sequences allow total relaxation of protons. The rate of cross-polarization depends on the proximity of protons to carbons, hence the contact time between carbons and protons must be optimized to ensure all carbon types are polarized to an equal extent.

Although  $T_{1p}$  values in soils are short  $(<10 \text{ ms})^2$  there is some evidence that results obtained by CP-MASS- $^{13}$ C-NMR are quantitative. In CP experiments maximum enhancement of different carbon types occurs at contact times and recycle times

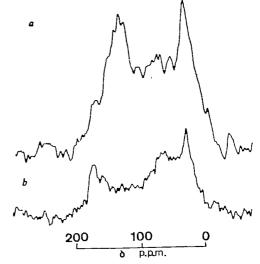

Fig. 3 CP-MASS spectra of a, Hokitika and b, Tirau soil. Spectra were collected in similar conditions as Mapourika soil.

of magnitudes used in the present experiments<sup>2</sup>. In addition, aromaticities of humic substances measured by CP, CP-MASS and conventional solution NMR are similar<sup>8,9</sup>, and CP-MASS has been widely used in the interpretation of closely related coal samples which have similar relaxation rates<sup>10-12</sup>.

Table 2 clearly shows that alkyl carbon is an important component of Mapourika soil. Because the alkyl signal is centred around 30 p.p.m. much of this carbon is polymethylene [(CH<sub>2</sub>)<sub>n</sub>]. The evidence for polymethylene in soils has been reviewed<sup>13</sup>. Aliphatic carbon  $\alpha$  to oxygen is also an important component of the soil; about 35% of the carbon is in this form. Small amounts of acetal carbon are also present. The O-alkyl and acetal carbon probably originate from carbohydrates. The ratio of O-alkyl to acetal carbon is 4:1 which, bearing in mind the approximate nature of the results, is consistent with hexose sugar units such as those in cellulose. About 10% of the carbon in Mapourika soil is carboxylic. This is in excellent agreement with typical values obtained for humic acids by conventional functional group analysis<sup>14</sup>.

It had been assumed that all carboxylic carbons in soil organic matter are attached to aromatic rings, however, Anderson and Russell<sup>15</sup> suggest that polymaleic acid-like molecules are important components of humic substances; that is, many of the carboxylic groups are attached to alkyl groups. The aromaticity (fraction of carbon which is aromatic,  $f_a$ ) of the Mapourika soil is low (~15%). The fraction of aromatic carbon is only slightly higher than the fraction of carboxylic carbon (10%). Much of the aromatic carbon is clearly not attached to carboxylic groups, as a significant proportion of the aromatic carbon is oxygenated or protonated. Hence, our results suggest that many of the carboxylic carbons are bound to aliphatic carbon<sup>15</sup>.

The spectra of the other soils (Figs 2, 3) show that the structure of soil organic matter can vary widely from soil to soil. The

degree to which different functional groups can be resolved depends on the preponderance of one carbon type to another. Most of the detail present in the spectrum of Mapourika soil is also present in the spectrum of Ikamatu soil (Fig. 2b) but the greater amounts of acetal and aromatic carbon mean that different carbon types are not so well resolved. The Hokitika soil is a case in point (Fig. 3a); about 37% of the carbon is aromatic and 27% alkyl. The O-alkyl and acetal carbons are not resolved, nor are substituted and unsubstituted aryl carbon resonances.

Even though unsuitable rotors were used, the three soils (Maungatua, Okarito and Te Kopuru) previously investigated by CP-MASS-NMR<sup>3</sup> show enough detail to allow them to be classified with the soils described above. Maungatua humic silt loam is highly aliphatic and similar in organic structure to the Mapourika soil except the O-alkyl and acetal carbon content is much lower. The other two soils (Te Kopuru and Okarito) are of more aromatic character and similar to Ikamatu soil. Nevertheless, these soils also show that the O-alkyl and acetal content can vary considerably<sup>3</sup>.

Figures 1 and 2 show that further, qualitative information is available from CP-MASS-13C-NMR spectra. Mapourika soil shows evidence of carbon resonances at 61 p.p.m., probably due to  $-CH_2OH$  carbon. There is also resonance at  $\delta$  55 p.p.m. which is possibly methoxy carbon. The Ikamatu spectrum (Fig. 2b) offers very tentative evidence for ketone carbon at

Clearly, CP-MASS-13C-NMR has enormous potential in soil science. No other analytical technique reveals such structural detail on the nature and forms of organic carbon. More extensive studies than those reported here may clarify the various processes resulting in soil formation. From our results it is too early to comment on genetic relationships between soils, because variations in structure of organic matter between horizons of the same soil may be larger than differences between soils. Nevertheless, we can comment on humification processes. We have investigated the decomposition of plant litter by wet chemical and solid state NMR techniques. Detailed experimental data are available elsewhere 16. The CP-MASS-13C-NMR spectra of beech and pine leaves that have been microbiologically aged for 2 yr are shown in Fig. 4. Note that the major carbon types identified in some of the soils described in this study (Figs 1 and 2) are also those present in aged plant litter. The discrete

resonances in Figs 1 and 2 apparently represent decomposing organic matter, and the broad underlying resonances such as those in Fig. 3 represent humified material. Thus our results clearly show that CP-MASS-13C-NMR is ideal for studying the degree of humification and humification rates of soils.

### Marshrock formed by iron sulphide and siderite cementation in saltmarsh sediments

#### K. Pye

Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, UK

The formation of authigenic sulphides and other iron minerals has proved interesting both in studies of palaeomagnetism<sup>1</sup> and palaeosalinity reconstructions of Pleistocene and older sediments<sup>2,3</sup>. Iron sulphide and siderite-cemented nodules, concretions and layers are fairly common in the geological record<sup>4-6</sup>, but there is little evidence of their formation in modern environments. Accounts of authigenic iron minerals forming today in marine and brackish sediments generally refer only to 'micro-concretions' 10-500 µm in size, many of which have a 'framboidal' texture<sup>3,7,8</sup>. I describe here 'macroconcretions' and cemented layers which are now forming within intertidal marsh sediments at Warham, Norfolk, UK. Parts of these marshes are only 30 yr old, indicating how quickly early diagenetic cementation can occur. Siderite (FeCO<sub>3</sub>), greigite  $(Fe_3S_4)$  and possibly mackinawite  $(FeS_{1-x})$  are the main cementing agents. The term 'marshrock' is proposed for the cemented sediments by analogy with calcareous beachrock9,10. The formation of siderite-monosulphide concretions in the Warham sediments probably reflects a high 'reactive iron' content and limited sulphate arising from rapid sedimentation and burial of organic matter during the early stages of marsh

The Warham marshes form part of an almost continuous series which extend 35 km between Cley and Holme on the north Norfolk coast. They are open coast marshes, partly protected by barrier islands, spits and intertidal sand flats. Warham has an Upper Marsh (2.7-3.0 m OD) and a Lower Marsh (1.9-2.1 m OD), to seaward of which is an area of unvegetated intertidal sand flats (1.7-1.9 m OD)11. The Upper Marsh and Lower Marsh are covered by ~6% and 55% of tides respectively11

Cemented deposits have only been observed within the Lower Marsh sediments, and are best exposed along the banks of tidal creeks and a low cliff which marks its seaward edge, especially after spring tides when creek beds are subject to scour. Air photographs show that in 1948 most of the Lower Marsh area was unvegetated and possessed no distinct creek system, but that by 1960 vegetation was well established and the creek system

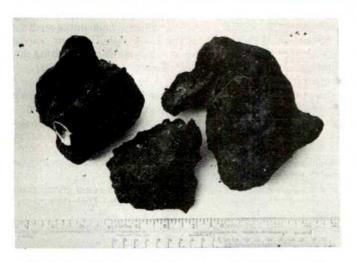

Fig. 1 Iron sulphide and siderite-cemented concretions from the Lower Marsh at Warham. Note the intact shell in the left-hand concretion.

had developed<sup>12</sup>. The marsh sediments are therefore mostly <30 yr old and the cemented layers and concretions must have formed within this time.

Observations suggest that cemented sediments occur discontinuously throughout the Lower Marsh area, but not in the Upper Marsh or intertidal flat sediments. The upper 1–1.5 m of Upper Marsh sediments are oxidized, but it is not known whether concretions and layers are present below this zone at elevations corresponding to those on the Lower Marsh. Preliminary observations elsewhere on this coast, however, support the conclusion that active concretion formation takes place only in younger lower marsh sediments.

The uppermost 30-40 cm of the Lower Marsh sediment column at Warham consists of brownish, organic-rich silty sands which overlie at least 1 m of black sands and silty sands. These colour zones correspond respectively to the 'hydroxide' and 'monosulphide' zones previously identified in Dutch coastal sediments<sup>13</sup> and in the Wash<sup>9</sup>. At Warham no lowermost grey 'bisulphide' zone is visible, but may be present beneath the monosulphide zone at depth.

The concretions and cemented layers are found within the black monosulphide zone, often in its upper part. Concretions are rounded and up to 40 cm in diameter (Fig. 1), but may be larger and more irregular in shape due to intergrowth of two or more neighbouring concretions. In some places continuous concretionary layers 15-25 cm thick can be traced laterally for 3 or 4 m. Many concretions and layers display 3-5 cm long tubular projections which often still contain recognizable rootlets. Some concretions also show clear horizontal grain size laminations which can be traced laterally into adjacent non-cemented sediments. Both these features testify that cementation has occurred within the marsh sediments and that the concretions are in situ. Some cemented material has been reworked in areas of localized bank erosion and is found as isolated fragments in creek beds and on the upper part of the intertidal flats. Such concretions usually have extensive surficial oxidation and bryzoan or algal encrustation.

Fresh specimens of cemented material are black though they may contain veins and patches of oxidized brown pigment. The concretions are hard, and there is a fairly sharp transition to the surrounding non-cemented sediment. Many specimens contain intact and broken shells, detrital chert pebbles, and fragments of macro-organic matter.

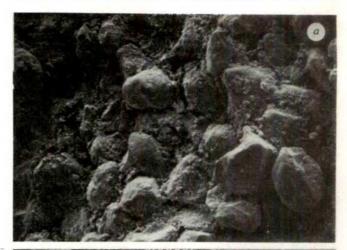

The material generally has a grain-supported fabric, with medium and fine-sized quartz representing >70% of the framework grains. Scanning electron microscopy (SEM) shows that the framework grains are cemented by rounded, granular aggregates or spherules  $2-5~\mu m$  in diameter (Fig. 2). The

spherules themselves seem to consist of individual particles up to 0.5 µm in size, many of which have an incomplete cubic form (Fig. 2b). Energy dispersive analysis (EDAX) under the SEM has detected large amounts only of iron and sulphur in these particles, with subsidiary aluminium, silicon and manganese.

The cemented sediments disintegrate completely within a few hours, with emission of H<sub>2</sub>S and CO<sub>2</sub>, when allowed to stand in cold HCl, suggesting that pyrite and marcasite, which are insoluble in HCl<sup>2,14</sup>, are not major components of the cement. Greigite, mackinawite and siderite are HCl-soluble, however. X-ray diffraction data (Table 1) confirm the presence of siderite and greigite, but do not confirm mackinawite or other form of FeS. The presence of a monosulphide other than greigite is suggested indirectly by the fact that some of the cement oxidizes rapidly to a brown colour on exposure to air, whereas greigite is stable in air and can withstand heating to 238 °C for 165 h without alteration<sup>15</sup>. Several unidentified X-ray peaks, which disappear after HCl treatment, may represent mackinawite or other monosulphide, although they do not correspond exactly to previous data for such minerals.

Siderite is apparently the major constituent of the cement in many concretions, although greigite and monosulphides are probably responsible for the black coloration. Approximately 20% of a sample of freshly crushed cement was attracted by a magnet, a property characteristic of greigite but not of siderite or mackinawite 15.

Both the formation of concretions and the dominance of siderite and greigite rather than pyrite in the Warham Lower Marsh may be explained in terms of the balance between 'reactive' iron and available sulphate (and therefore H<sub>2</sub>S) within the sediments. Berner<sup>16</sup> has demonstrated that both concretionary and layer concentrations of iron sulphide will probably

form where there is a relatively high ratio of reactive iron to reducible sulphur. In such conditions outward diffusion of H<sub>2</sub>S from an organic-rich source area is restricted by immediate reaction with dissolved Fe2+ and resultant precipitation of FeS close to the source area. Because FeS is relatively insoluble, the concentration of dissolved iron in this area is reduced, thereby creating a diffusion gradient which allows further iron to move towards the incipient concretion.

The first-formed iron sulphide precipitates, mackinawite and greigite, are thermodynamically unstable relative to pyrite and should be converted to the latter by reaction with polysulphide ions 17-19. However, this diagenetic transformation can be arrested where sulphate availability is limited and monosulphides may be preserved<sup>20</sup>. This situation may occur in seawater but is most common in freshwater lakes and estuaries which contain less dissolved sulphate. Moreover, sediments which possess a high concentration of dissolved Fe<sup>2+</sup>, and in which the supply of H<sub>2</sub>S rapidly becomes depleted, may attain supersaturation with regard to non-sulphide iron minerals such as siderite and vivianite (Fe<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>.8H<sub>2</sub>O), thereby leading to their precipitation<sup>21-24</sup>

In saltmarshes which do not occur within brackish water estuarine settings, as at Warham, the most important factor leading to rapid depletion of sulphate and H<sub>2</sub>S is probably a high rate of sediment accretion. For any given sulphate concentration, more rapid accretion results in more rapid bacterial sulphate reduction due to burial of more highly reactive organic matter<sup>25,26</sup>. If deposition is sufficiently rapid, the rate of sulphate reduction may be so great that the sulphate supply is exhausted before FeS is completely altered to pyrite<sup>1,26</sup>. On the north Norfolk coast, accretion rates on marshes less than 30 yr old are of the order of 1.0-1.7 cm yr<sup>-1</sup> (ref. 27), and may provide the conditions necessary for rapid sulphate exhaustion, monosulphide preservation and siderite formation. On older and higher marshes, accretion rates are much lower, of the order of  $0.002 \,\mathrm{cm}\,\mathrm{yr}^{-1}$  (ref. 27), and suitable conditions for these diagenetic processes are much less likely. This would explain why no concretions appear to be actively forming within the Upper Marsh at Warham and other 'high' marshes on the Norfolk coast. Because marsh accretion rates are initially most rapid and seem to decrease exponentially with time<sup>27</sup>, siderite/ greigite concretion formation may only occur in sediments deposited during the first few decades of marsh growth.

The nature of authigenic iron minerals formed in salt marsh sediments will depend on several factors other than accretion

rate (which reflects sediment availability and type, tidal regime and relative sea level movements), which include initial reactive iron content, the character of marsh vegetation (which controls organic production rates), and seasonal fluctuations in the activity of sulphate-reducing bacteria (which are largely temperature-controlled). Because these conditions vary between regions, marshes in different areas of similar age may possess distinctive suites of authigenic iron minerals. Sideritegreigite concretions and layers are unlikely to form in slowly accreting marsh sediments with a low reactive iron content; in such situations disseminated pyrite crystals and framboids would probably form very quickly, as has been reported from marsh peats in the eastern US<sup>28</sup>

The apparent importance of accretion rate as a control in the formation of authigenic iron minerals means that attempts to infer palaeosalinities associated with formation of iron concretions in fossil deposits must proceed with caution.

I thank Peter Friend for comments and discussion.

## **Ipswichian fauna of Victoria Cave** and the marine palaeoclimatic record

#### Melvyn Gascoyne\*, Andrew P. Currant† & Thomas C. Lord‡

- \* Department of Geology, McMaster University, Hamilton, Ontario, Canada L8S 4M1
- † Department of Palaeontology, British Museum (Natural History), Cromwell Road, London SW7 5BD, UK
- ‡ Pigyard Museum, Settle, North Yorkshire, UK

The lack of age dating methods which can be applied beyond the limit of radiocarbon dating makes the global correlation of continental climatic events and stratigraphic sequences with the continuous palaeoclimate record, obtained by isotopic and faunal analysis of deep-sea sediment cores 1-3, a difficult task; often only a relative time scale can be obtained using complex and perhaps tenuous litho- and biostratigraphical data. Speleothems may assist in this correlation, for embodied in their calcium carbonate structures are elemental and isotopic variations which indicate both their age and climatic conditions prevailing during their deposition. Speleothems may be reliably dated by the  $^{230}$ Th/  $^{234}$ U method to an age of  $\sim 350$  kyr BP providing they consist of non-porous, unrecrystallized calcite which is essentially free of clastic detrital sediments4-6. They

may also provide palaeoclimatic information for previously glaciated areas (1) because their presence indicates that groundwater movement was not prevented by ice formation at the surface, and CO2 was produced in the soil zone by root respiration and plant decay (limestone bedrock may then be dissolved and reprecipitated as speleothems in caves below the surface), and (2) because of the variations in stable isotopic content and fluid inclusion waters contained therein4.7.8. Additional climatic and chronological information may be obtained where speleothems are interstratified with deposits characteristic of a particular climatic regime, and with deposits containing organic remains. We describe here the results of dating speleothems encrusting the remains of mammals from Victoria Cave in northern England, and discuss their significance in terms of the correlation between continental and oceanic palaeoclimatic records.

· SEEDER SEEDER

Victoria Cave is situated at an altitude of 440 m a.s.l. in a Carboniferous limestone scar north-east of Settle, North Yorkshire. The Victoria Cave Exploration Committee of the British Association for the Advancement of Science conducted excavations at the site from 1870 to 1878 and published details of the Pleistocene deposits9. Two quite distinct fossiliferous horizons were found, but we will consider here only the older of these, the Lower Cave Earth. Tiddeman records an interglacial mammal fauna from this deposit which included such animals as hyaena, hippopotamus and narrow-nosed rhinoceros. He observed that the Lower Cave Earth was truncated at the cave mouth by glacial till, while inside the cave it was overlain by laminated clays. It was reasoned that the till and laminated clays were laid down during the last glacial period and that the lower Cave Earth and its contained fauna belonged to the preceding interglacial. The relationship of these deposits is shown in Fig. 1.

Further (unpublished) excavations by Lord in 1937 revealed mammal bones, teeth and deer antler lying on a surface within the Lower Cave Earth, covered by a layer of calcite flowstone to a depth of  $\sim 10$  cm. Their unweathered condition indicated that the time between their introduction into the cave and their burial beneath the flowstone was not great. All the samples from which the present series of  $^{230}$ Th/ $^{234}$ U dates are derived were taken from blocks found during Lord's excavations, now housed in the Pigyard Museum at Settle. Re-examination of material from Victoria Cave has confirmed the presence of the above mammals recorded by Tiddeman in the Lower Cave Earth (and its interbedded speleothems). A list of the Victoria fauna is given in Table 1.

This faunal assemblage is a classic example of the late Pleistocene 'hippopotamus fauna' as defined by Sutcliffe<sup>10</sup> on the basis of material from Joint Mitnor Cave in Devon. He assigned the assemblage to the warmest part of the Eemian (=Ipswichian) interglacial. Palaeobotanical evidence from Trafalgar Square, London<sup>11</sup> and Barrington, Cambridgeshire<sup>12</sup> has demonstrated the association of the 'hippopotamus fauna' with

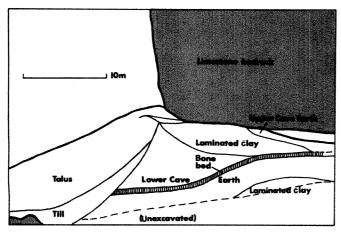

Fig. 1 Diagrammatic longitudinal section of the Pleistocene deposits of Victoria Cave.

Table 1 Fauna of the Lower Cave Earth in Victoria Cave

Species identified	Common name
Ursus arctos	Brown bear
Crocuta crocuta	Spotted hyaena
Panthera leo	Lion
Palaeoloxodon antiquus	Straight-tusked elephant
Dicerorhinus hemitoechus*	Narrow-nosed rhinoceros
Hippopotamus amphibius*	Hippopotamus
Megaloceros giganteus*	Giant deer
Cervus elaphus*	Red deer
Bos or Bison sp.	A bovine

<sup>\*</sup> Species present in the dated flowstone samples.

interglacial pollen spectra representing a period of climatic optimum (zone Ip IIb). At Swanton Morley, Norfolk, there is evidence for the continued existence of *Hippopotamus* into the declining phase of the interglacial (zone Ip III)<sup>13</sup>.

The 'hippopotamus fauna', which is represented at many localities in England and Wales, is remarkably constant in its composition and there is no evidence to suggest that this particular species grouping was present more than once in the British sequence. Many fluviatile deposits in southern Britain have produced an extraordinary abundance of remains of hippopotamus, yet it is virtually absent from similar deposits in adjacent parts of the continent strongly suggesting that we are dealing with an island fauna, and therefore, a period in which sea-level was sufficiently high to isolate Britain from Europe. Rare occurrences of *Hippopotamus* in France, in apparent 'Riss-Würm' contexts, may chart this animal's route from the Mediterranean area.

At Sewerby Cliff, Holderness, elements of the 'hippopotamus fauna' have been found in beach deposits in front of a buried cliff feature at 2-3 m above OD, slightly higher than the level of modern high water during spring tides at the same locality <sup>14</sup>. The elevation of the deposits suggests a correlation with the high sea-stand of isotope substage 5e <sup>1</sup>, thus precluding a younger age for the 'hippopotamus fauna'. However, their elevation may be due, in part, to local isostatic movement and crustal adjustment, so that correlation with the younger substages, 5c and 5a, cannot be completely ruled out unless the deposits can be assigned an absolute age. This has been possible in the case of the Victoria Cave fauna by dating the speleothems associated with the bone remains.

Seven samples of flowstone were analysed by the  $^{230}$ Th/ $^{234}$ U dating method, using analytical techniques and age calculations described elsewhere  $^{15}$ . The accuracy and precision of ages determined by this method are demonstrated by: (1) 12 analyses of a homogenized speleothem standard (mean age 47.8 kyr BP) have shown that the mean error determined by averaging  $1\sigma$  counting uncertainties ( $\pm$ 2.2 kyr) is comparable to the standard deviation of the determined ages ( $\pm$ 1.7 kyr) $^{16}$ ; (2) close agreement of ages determined by the McMaster laboratory with other laboratories for several homogenized carbonate standards has been found in the uranium-series interlaboratory comparison project  $^{17}$ , and (3) results of duplicated analyses of the same sample of several U-rich speleothems using the  $^{231}$ Pa/ $^{230}$ Th dating method show good agreement with  $^{230}$ Th/ $^{234}$ U ages  $^{16}$ .

All samples analysed consist of yellow to brown laminated calcite enclosing or overlying bones. Sections cut through the flowstones clearly showed that the calcite post-dated the bone. The results of 12 analyses are shown in Table 2. Except for three results (79000-1, 79001-1 and 79025-1) all ages fall within the interval 135-114 kyr BP. Re-determination of these three apparently younger samples gave ages within the 135-114 kyr interval (79000-2, 79001-3, -4, 79025-3). The initial younger ages are thought to be due to slight contamination by uranium which had migrated from the relatively U-rich fossil bones into the immediately adjacent calcite. The replicates were taken from calcite more removed from (and therefore stratigraphically younger than) the initial analyses, and hence were less likely to

be influenced by nuclide migration from the bone. The appreciably higher U content of the most anomalous age determination (79025-1) further supports this interpretation, although this distinction is not seen in the case of 79000.

The results indicate that members of the 'hippopotamus fauna' were present in the vicinity of Victoria Cave during or before the interval  $135 \pm 8$  to  $114 \pm 5$  kyr BP. More specifically, because the basal and top ages of sample 79025 are in normal stratigraphic sequence, and because the bone layer lies at the base of this deposit, the fauna of the Lower Cave Earth can be placed at or before 120 ± 6 kyr BP. This compares very favourably with the date of 125-120 kyr BP for substage 5e of the marine isotopic record<sup>1,18</sup>.

The association of Ipswichian pollen assemblages with the 'hippopotamus fauna' at several sites would suggest that the Ipswichian interglacial sensu stricto must therefore also coincide with substage 5e. However, the paucity of vertebrate fauna at the Ipswichian type locality at Bobbitshole, near Ipswich, Suffolk, makes a direct correlation with the Lower Cave Earth in Victoria Cave impossible. Elsewhere, there are reported discrepancies between what are apparently Ipswichian pollen assemblages and the associated mammal faunas, suggesting that some of the pollen assemblages assigned to the Ipswichian may actually represent other warmer stages<sup>19,20</sup>. Many of these difficulties arise from the unsuitability of the chosen type locality for this important phase of the Pleistocene. Despite such problems, the term 'Ipswichian' is widely applied to the last period in which the climate of the British Isles was as warm as, or warmer than, at present, though this is not strictly within the original definition of the term. This procedure is necessitated by the absence of any other acceptable name for the same phase. With this qualification, we feel justified in correlating the 'Ipswichian interglacial' of the British terrestrial sequence with substage 5e of the marine isotope record.

We thank Dr H. P. Schwarcz and Dr D. C. Ford for facilities and equipment for this work, and Dr A. J. Sutcliffe for helpful discussions and enthusiasm. The National Research Council of Canada provided financial support for this work. This is contribution no. 126 of the McMaster Isotopic, Nuclear and Geochemical Studies group.

## Phosphotyrosine-containing proteins isolated by affinity chromatography with antibodies to a synthetic hapten

#### Alonzo H. Ross, David Baltimore & Herman N. Eisen

Department of Biology and Center for Cancer Research. Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Tyrosine-specific protein kinases seem to be involved critically in cellular transformation by tumour viruses1-4, and may also be involved in the cellular response to epidermal growth factor<sup>5</sup>. To facilitate the identification and isolation of phosphotyrosinecontaining proteins (PT-proteins) we have sought to develop as a general reagent anti-O-phosphotyrosine antibodies. We show here that affinity chromatography with these antibodies is effective for the small-scale isolation of some PT-proteins, including p120, the transforming protein of Abelson murine leukaemia virus, and several unidentified proteins from Rous sarcoma virus (RSV)-transformed mouse fibroblasts.

New Zealand rabbits were injected repeatedly intradermally (i.d.), each time with ~1 mg of keyhole limpet haemocyanin containing ~30 p-azobenzyl phosphonate<sup>6</sup> (ABP) groups per 100,000 molecular weight  $(M_r)$ . Benzyl phosphonate, rather than phenyl phosphate, was chosen to avoid the loss of haptenic groups by the action of tissue phosphatases. For the first injection, the antigen was incorporated in complete Freund's adjuvant; for subsequent ones (on days 23, 33, 40 and 92) it was given in incomplete Freund's adjuvant. Anti-ABP activity in serum was monitored by a solid phase radioimmunoassay in which small tubes (Dynatech) coated with ABP<sub>30</sub>-bovine serum

albumin (BSA) were incubated with the rabbit antisera, washed and finally tested with <sup>125</sup>I-labelled *Staphylococcus aureus* Protein A to measure the extent of binding of rabbit immunoglobulin to the ABP-BSA.

Antibodies were isolated from the active sera by affinity chromatography on Sepharose to which was attached O-phosphotyramine. The latter was prepared by phosphorylating tyramine with P<sub>2</sub>O<sub>5</sub> (ref. 7). A strongly coloured side-product was precipitated by the addition of 1 vol ethanol and 13 vol n-butanol. O-phosphotyramine was then precipitated by addition of 15 vol ethyl acetate and recrystallized twice from ethanol/water. The recrystallized product migrated as a single component on TLC using isopropanol/H2O/conc. NH4OH (7:2:1) as solvent. On silica gel  $(R_F = 0.1)$  it was detected using  $I_2$ , ninhydrin and by UV absorption, and on cellulose ( $R_F = 0.2$ ) it was detected with ninhydrin. Its NMR spectrum was consistent with the expected structure. The recrystallized O-phosphotyramine was coupled to cyanogen bromide (CNBr)activated Sepharose 4B (30 mg per g) in 0.1 M NaHCO<sub>3</sub>. Immunoglobulins from anti-ABP serum (precipitated with 40%

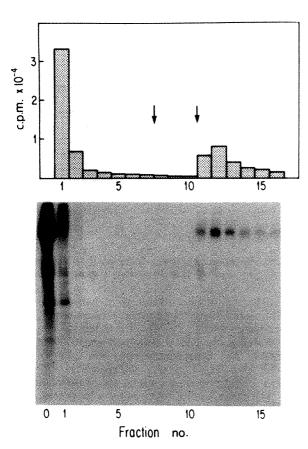

Fig. 1 Affinity chromatography of phosphotyrosine-containing proteins from an extract of Abelson virus-transformed B lymphocytes (ANN-1 cells). A crude preparation of p120 (40 μg) was phosphorylated by reaction for 30 min on ice with 5 μCi[γ-³2P]ATP in 10 mM MnCl<sub>2</sub>, 1 mM phenylmethylsulphonyl fluoride (PMSF), 100 kallikrein units aprotinin ml<sup>-1</sup>, 150 mM Tris pH 8.0. After addition of 20 mM Na<sub>2</sub>-EDTA, the reaction mixture was diluted with an equal volume of buffer I (0.5% NP-40, 150 mM NaCl, 100 units aprotinin ml<sup>-1</sup>, 0.1 mg ml<sup>-1</sup> ovalbumin, 10 mm Tris pH 8.0) and applied to a 0.15 ml Sepharose column of anti-ABP antibodies (0.75 mg immunoglobulin per ml Sepharose). The column was washed with buffer I (fractions 2-7), then with buffer II (fractions 8-10) and finally with buffer III (fractions 10-16). Buffer II differed from I only in that II contained 20 mM phosphoserine, 20 mM phosphothreonine, 50 mM NaCl and 3.3 mM Na<sub>2</sub>HPO<sub>4</sub>. Buffer III differed from II in that III had 40 mM phenyl phosphate in place of phosphoserine and phosphothreonine. Each fraction was 0.5 ml. The protein precipitated with 5% perchloric acid from a 25 μl sample of each fraction was collected on a Millipore filter and counted in Bray's solution (upper panel). Of the total perchloric acid-precipitable radioactivity applied to the column, ~50% was recovered. A sample of each fraction and of the original reaction mixture (fraction 0') was also analysed by electrophoresis in 10% SDS-polyacrylamide gels<sup>13</sup>, followed by autoradiography of the dried gels (lower panel). The 'fraction 0' sample had half the volume of the other fractions.

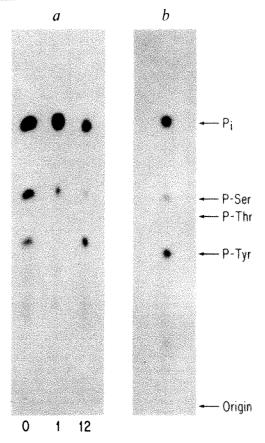

Fig. 2 Phosphoamino acid analyses by high voltage paper electrophoresis. Proteins were precipitated with 5% perchloric acid and washed successively with 5% perchloric acid, 5% trichloroacetic acid and acetone. The samples were hydrolysed for 2 h at 100 °C in 6M HCl, dried and subjected to high voltage electrophoresis in pyridine-acetic acid (pH 3.5) on Whatman 3-MM paper at 2,400 V for 1 h. a, Samples from the reaction mixture (fraction 0), and fractions 1 and 12 of the column described in Fig. 1. b, Phenyl phosphate-eluted material from RSV-transformed fibroblasts labelled as intact cells with <sup>32</sup>P-inorganic phosphate (see Fig. 3 legend), P-Ser, phosphoserine; P-Thr, phosphothreonine; P-Tyr, phosphotyrosine.

saturated ammonium sulphate) were applied to the phosphotyramine-Sepharose column at room temperature. After washing the column with buffer (150 mM NaCl, 10 mM NaH<sub>2</sub>PO<sub>4</sub> pH 7.4) at room temperature and then at 45 °C, the retained antibodies were eluted at 45 °C with modified buffer containing 40 mM phenyl phosphate, 50 mM NaCl and 3.3 mM NaH<sub>2</sub>PO<sub>4</sub> pH 7.4. Phenyl phosphate was removed from the eluate by dialysis. The hapten-eluted protein accounted for

Table 1 Specificity of anti-ABP antibodies measured by competition radioimmunoassay

Competitor	% Inhibition
Phosphotyrosine (25 µM)	2
Phosphotyrosine (74 µM)	8
Phosphotyrosine (220 µM)	16
Phosphotyrosine (670 µM)	28
Phosphotyrosine (2 mM)	48
Phosphoserine (2 mM)	<1
Phosphothreonine (2 mM)	< 1

Anti-ABP antibodies (3.3  $\mu$ g in 50  $\mu$ l phosphate-buffered saline (PBS)) were incubated in polystyrene tubes (Dynatech) for 1 h at room temperature. After washing, the tubes were incubated for 1 h at room temperature with 9 ng  $^{125}$ I-(azophenyl phosphate)<sub>7</sub>-RNase and the above inhibitors in 20  $\mu$ l PBS. The tubes were then washed and counted. In the absence of inhibitors  $\sim 30\%$  of  $^{125}$ I-labelled probe was bound. The high concentration of phosphotyrosine required for inhibition was probably due to the multivalency of the azophenyl phosphate-RNase.

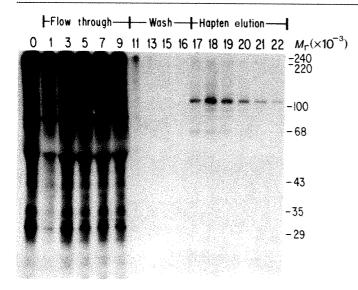

Fig. 3 Isolation of phosphotyrosine-containing proteins from RSV (Schmidt-Ruppin strain)-transformed mouse (BALB/c) fibroblasts;  $3\times10^6$  cells were incubated with 0.25 mCi  $^{32}PO_4$  in phosphate-free medium for  $3\frac{1}{2}$  h. The cells were washed with ice-cold medium and extracted three times with 1 ml ice-cold 1% Triton X-100, 0.5% deoxycholate, 0.1% SDS, 0.1% BSA, 10 mM Na<sub>2</sub>-EDTA, 10 mM NaF, 150 mM NaCl, 100 units aprotinin ml<sup>-1</sup>, 1 mM PMSF, 10 mM sodium phosphate pH 7.3. After scraping residual material from the plastic surface with a rubber policeman the extract was homogenized (twelve strokes in a Dounce homogenizer) and centrifuged at 105,000g for 1 h. The supernatant was generally stored at -20 °C after addition of glycerol to 30% (v/v). After thawing, samples were mixed with 1 vol buffer I (see Fig. 1) and applied to the column (fractions 1-5), followed by additional buffer I (fractions 10-16) and finally by elution with buffer III (fractions 17-22), which contained phenyl phosphate. The protein from 90 µl of each 0.5 ml fraction was precipitated with 1 ml acetone (-20 °C), boiled for 2 min in SDS-2-mercaptoethanol and subjected to SDS-polyacrylamide gel electrophoresis. This figure shows the autoradiograph of the dried gel. Sample 0 is the 105,000g supernatant of the total cell extract. Molecular weight markers are indicated at the right. The faint band at  $M_r = 36,000$  might correspond to the <sup>32</sup>P-p36 protein described elsewhere <sup>14,15</sup>.

~95% of the ABP-binding activity of the immunoglobulin fraction and corresponded to 0.9 mg antibody per ml serum. By fluorescence quenching<sup>8</sup> the affinity (equilibrium association constant) of the purified antibodies for the 2,4-dinitrophenyl (DNP) derivatives of p-aminobenzyl phosphonate and of paminophenyl phosphate was estimated to be  $\sim 4 \times 10^6 \, \text{mol}^{-1}$  at 20 °C. (Because of the simplicity of these ligands and the DNP moiety which was introduced to facilitate affinity measurement<sup>10</sup>, the observed equilibrium constants are only approximations of the affinity for phosphotyrosine in PT-proteins.) These ligands did not specifically quench the fluorescence of anti-phenyl arsenate antibodies. As judged by competitive radioimmunoassay with 125I-(azophenyl phosphate)7-ribonuclease as the radiolabelled ligand, the anti-ABP antibodies had no measurable affinity for O-phosphoserine or O-phosphothreonine (Table 1). (The azophenyl phosphate-ribonuclease was prepared from diazotized p-aminophenyl phosphate, which was synthesized as described above for O-phosphotyramine.)

An 'affinity' column, prepared by coupling the purified anti-ABP antibody to CNBr-activated Sepharose, was tested for its ability to bind a crude preparation of the transforming protein (p120) of Abelson murine leukaemia virus. This protein (given by A. Dasgupta) was phosphorylated with  $[\gamma^{-32}P]$ ATP in conditions where essentially all the  $^{32}P$  incorporated into p120 was in the form of O-phosphotyrosine<sup>2</sup>. The <sup>32</sup>P-p120 was retained by the column, from which it was specifically eluted by phenyl phosphate, but not by phosphoserine or phosphothreonine (Fig. 1). In other experiments (not shown), neither 40 mM p-nitrobenzoic acid nor 10 mM sodium phosphate eluted the p120. Moreover, phosvitin, which is rich in phosphoserine and phos-

phothreonine but lacks O-phosphotyrosine, did not bind to the affinity column. The failure of the phosphorylated p120 to adhere to a similar Sepharose column that had been prepared with anti-phenyl arsenate antibodies in place of the anti-benzyl phosphonate antibodies provided additional evidence of specificity. (Antibodies to phenyl arsenate have been reported to cross-react strongly with phenyl phosphonate11; because these antibodies did not retain PT-proteins they probably react only weakly with benzyl phosphonate and phenyl phosphate.)

Aliquots of the column fractions described in Fig. 1 were hydrolysed with 6 M HCl and analysed by high voltage paper electrophoresis (Fig. 2a). O-phosphotyrosine was virtually absent from hydrolysates of the pass-through from the affinity column and was enriched in the <sup>32</sup>P-protein eluted by phenyl phosphate.

The affinity column was also able to bind <sup>32</sup>P-PT-proteins that had been formed by incubating intact cells with <sup>12</sup>P-labelled inorganic phosphate (Pi). Schmidt-Ruppin (RSV)-transformed mouse fibroblasts labelled in this way, were lysed by detergent and the lysates applied to the affinity column. Figure 3 shows an SDS-polyacrylamide gel electrophoretic analysis of the proteins that were applied to and eluted from the column, and Fig. 2b shows the <sup>32</sup>P-phosphoamino acids in hydrolysates of the eluted proteins. It is evident that the affinity column selected a discrete set of phosphoproteins highly enriched in O-phosphotyrosine. One of the conspicuous PT-proteins detected (PT-110) has not to our knowledge been previously reported, perhaps because of its high molecular weight ( $M_r = 110,000$ ; Fig. 3)<sup>12</sup>. Because the amount of PT-110 isolated from the RSV-transformed cells was much greater than that obtained from uninfected cells (Y. Onodera, personal communication), PT-110 may be a substrate for pp60src, or for another kinase activated by pp60src, and may play a part in expression of the transformed phenotype.

The specific retention of PT-proteins by antibodies to benzyl phosphonate depends on cross-reactions in which the antibodies have sufficiently high affinity for O-phosphotyrosine and negligible affinity for O-phosphoserine and O-phosphothreonine. The intrinsic affinity for O-phosphotyrosine has to be relatively high because there is probably only a single O-phosphotyrosine residue per PT-protein and, therefore, few if any opportunities for multivalent binding. It is likely that the anti-benzyl phosphonate antibodies do not have the same affinity for every PT-protein because of local differences in charge density and in accessibility of phosphotyrosine residues. Nonetheless, it seems from preliminary data that ~50-60% of the <sup>32</sup>P-PT-proteins were recovered in the phenyl phosphate eluate. Phenyl phosphate, rather than denaturing agents, was used to recover PT-proteins from the column so as to enhance the specificity of the elution and to prolong the useful life of the column. It is possible that higher affinity antibodies can be generated using haptenic groups, for example, p-azophenyl phosphate, that are closer in structure to phosphotyrosine than p-azobenzyl phosphonate.

This research was supported in part by NCI grants CA-14051 and CA-15472, American Cancer Society grant MV-34L, and training grant 5-T32-CA-09255 from the NCI.

# Hot spots of frameshift mutations induced by the ultimate carcinogen N-acetoxy-N-2-acetylaminofluorene

Robert P. P. Fuchs, Nicole Schwartz & Michel P. Daune

Laboratoire de Biophysique, Institut de Biologie Moléculaire et Cellulaire du CNRS, 15 rue René Descartes, 67084 Strasbourg Cédex, France

An important step in carcinogenesis is thought to be the initial attack of the DNA molecule by a so-called ultimate carcinogen. More than 90% of the carcinogens tested have been found to be mutagens in bacterial systems1. The covalent binding of the ultimate carcinogen to the DNA bases or phosphate groups creates a premutational lesion that in vivo is processed by the repair, replication and recombination enzymes, and eventually may be converted into a mutation. Being interested in the way that an initial premutational event is converted into a stable heritable mutation, we have sequenced stable mutations in a gene that has formed covalent adducts in vitro with N-acetoxy-N-2-acetylaminofluorene (N-AcO-AAF, a model for the ultimate metabolite of the rat liver carcinogen 2-acetylaminofluorene AAF). We show here that the mutations are mainly frameshifts involving G · C base pairs, and that certain base pairs (hotspots) are affected at relatively high frequences. These results fit a model in which N-AcO-AAF-modified guanine acts as a non-coding base that during replication results in deletion of the modified residue.

In vivo studies have shown the mutagenicity of AAF and its derivatives in both bacterial<sup>2,3</sup> and eukaryotic<sup>4</sup> systems. N-AcO-AAF reacts in vitro with DNA leading mainly to the formation of a guanine adduct<sup>5</sup>, N-2-(deoxyguanosin-8-yl)-acetylaminofluorene (80%) and to at least three minor adducts (N.S., R.P.P.F. and M.P.D., unpublished results), one of which has been characterized as 3-(deoxyguanosin-N<sup>2</sup>-yl)-acetylaminofluorene<sup>6</sup>. Studies by our group showed that binding of N-AcO-AAF to DNA resulted in a local distortion of the DNA helix around the C-8 adduct<sup>7-9</sup>, which we have called the insertion-denaturation model<sup>10</sup>. A similar model has been proposed by other investigators<sup>11</sup>. We describe here the analysis

of forward mutations induced in the tetracycline-resistance gene of pBR322 by directing the chemical reaction of the carcinogen to a small restriction fragment (BamHI-SalI) inside the antibiotic-resistance gene. These two restriction enzymes each cut pBR322 only once and both sites reside in the tetracyclineresistance gene. The strategy used is outlined in Fig. 1. The resulting small restriction fragment (275 base pairs (bp); 6S fragment) modified to various extents with N-AcO-AAF (3H ring) was reinserted by in vitro ligation into the non-reacted large (BamHI-SalI) pBR322 restriction fragment (16S fragment). The ligation mixture was used to transform CaCl2treated Escherichia coli recipient cells. Mutants are selected for ampicillin (Ap) resistance and tetracycline (Tc) sensitivity. The induction of SOS functions by UV irradiation of the cells before transformation increased the observed mutation frequency. The plasmid DNA of such mutants was analysed for sequence changes in the fragment where the AAF binding had been directed.

Mutation frequencies were calculated as the ratio of ApR Tc<sup>S</sup>/Ap<sup>R</sup> clones. The frequency in the control experiment in which the 16S fragment was ligated to a non-modified 6S fragment was 0.4% when the bacteria were not treated with UV before the transformation step; when UV treatment was applied, the frequency was 0.6%. When analysed by gel electrophoresis, the plasmid DNAs isolated from such clones were always shorter than the original pBR322, in general by 0.2-0.8 kilobases (kb). The restriction analysis pattern showed that these mutant DNAs had retained the unique EcoRI site but that in general they had lost both the BamHI and SalI restriction sites. We call these mutants class I mutants and suggest that they mainly arise from the dimerization of the 16S fragment. Such dimers, which have the Ap<sup>R</sup> Tc<sup>S</sup> phenotype, are then converted to smaller plasmids (monomers) through *in vivo* recombination. Work is in progress to lower this mutation background by using an alkaline phosphatase-treated 16S fragment<sup>12</sup>. Class I mutants were easily recognized and excluded from the pool of mutants to be sequenced.

When 6S-AAF fragments ligated to the non-modified 16S fragment are used to transform *E. coli* the transformation efficiency decreases with increasing levels of bound AAF residues (Fig. 2). The extent of this AAF-dependent inactivation of transformation is strongly related to the general repair genotype of the recipient cell (R.P.P.F. and E. Seeberg, in preparation). One also finds a corresponding increase in the mutation

Table 1 Properties	of variou	s mutants
--------------------	-----------	-----------

Description of mutation	Mutant no.	Strain	Induction of SOS functions	Average no. of bound residues per 6S fragment	Sequence near the n	autation
	4	AB 1886	+	2.0	511 524	529
-1 deletion of G 520 or 521	30	AB 1886	-	2.8	GGGTATGGTGGC	AGGCCCG
	41	AB 1157	+	13.8		
	45	AB 1157	+	2.8		
					381 390	399
-1 deletion of G 389 or 390	32	AB 1157	+	8.8	TCTACGCC[G]AC	GCATCGT
					428	446
-2 deletion of GC 435-436	34	AB 1157	+	6.6	GTTGCTGGCGCC	TATATCG
or 437–438 or CG 436–437	36	AB 1157	+	8.8		
Addition of a C within	36				518 +1 <u>C</u>	536
sequence 526–528	50				GTGGCAGGCCCG	TGGCCGG
-2 deletion of GC 548-549					540	558
or 550–551 or CG 549–550	33	AB 1157	+	13.8	ACTGTTGGGCGC	CATCTCC
-1 deletion of G 416 and					406	424
double transition at 414–415	35	AB 1157	+	8.8	$\begin{array}{c} CATCACCG[\overline{GCG}]C\\ double & \uparrow -1\\ transition & \overline{AT} \end{array}$	CACAGGT

The sequences in the table are the wild-type sequences with the numbering defined by Sutcliffe<sup>15</sup>. The bases involved in the deletion mutations are boxed with dotted lines. The different possibilities to obtain a given mutated sequence are shown. Mutant 36 exhibits two mutations: a-2 deletion as in mutant 34 and a+1 addition of a C residue within the sequence CCC at positions 526-528. Mutant 35 has got a-1 deletion of a G at position 416 and a double transition,  $GC \rightarrow AT$ , at position 414-415.

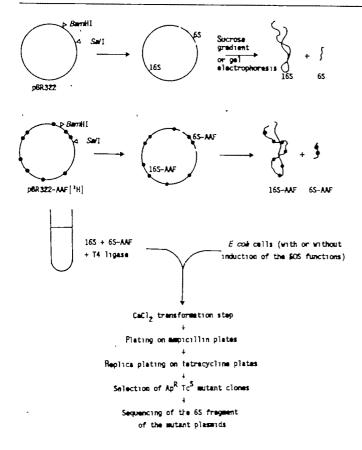

Fig. 1 Strategy for the site-directed mutagenesis experiments. The  $E \, coh$ strains used were AB 1157 or AB 1886 (ref. 18), N-AcO-AAF (<sup>9</sup>H ring) was synthesized as described previously<sup>10</sup> (specific activity 196 mC mmol<sup>-1</sup>) N-AcO-AAF ('H ring) reaction with supercolled plasmid DNA was performed in 10 mM ris, 1 mM EDTA, pH 8 (TE) buffer containing 5% of ethanol (DNA concentration 50 µg ml<sup>-1</sup>). Removal of unbound fluorene derivatives was achieved by four successive ethanol precipitations. The number of AAF residues bound per plasmid molecule was determined as previously described20. Samples of pBR322 reacted with N-AcO-AAF to various extents (ranging from 0 to 2.5% of modified bases) were digested with Bamili and Sali restriction emymes (Boehringer, Mannheim). The large (16S) and the small (6S) fragments were separated and purified either by velocity sedimentation on sucrose gradients (5-20%) or by electro-phoresis on 0.8% agarose or on 8% polyacrylamide gels followed by electroelution T4 DNA ligase (Biolabs) was used to ligate the unmodified 16S fragment with either the unmodified 6S fragment or the 6S fragments obtained from the various AAF-modified pBR322 samples (6S-AAF). The ligation was performed in the conditions specified by the T4 DNA ligate manufacturer. The DNA fragment concentrations were  $16.5 \, \mu g \, \mathrm{ml}^{-1}$  for the  $168 \, \mathrm{fragment}$  and  $7.5 \, \mu g \, \mathrm{ml}^{-1}$  for the  $68 \, \mathrm{fragment}$ . UV irradiation of the cells before transformation. In some cases, the E coli cells were UV irradiated before the transformation procedure to induce the cellular SOS response The cells were UV irradiated as a suspension in 0.01 M MgSO. with a germicidal lamp (15 W, Phillips) at a dose giving about 50% survival (that is, 60 J m<sup>-2</sup> for the wild-type strain, AB 1157, 6 J m<sup>-2</sup> for the wind strain, AB 1886) The cells were then incubated in LB medium for 30 mm at 37 °C to allow expression of the SOS functions. E. coli transformation and selection of the ampicillim-resistant (Ap<sup>®</sup>) and tetracycline-sensitive (Tc<sup>®</sup>) clones. The E coll were made competent for transformation by the classical  $CaCl_2$  treatment procedure<sup>21</sup>. The different ligation mixtures were diluted by a factor of 100 in (10 mM Tris), 10 mM CaCl<sub>2</sub> and 10 mM MgCl<sub>2</sub> (pH 7) and used to transform the competent cell suspension by mixing 1 vol of the DNA solution with 2 vol of the concentrated B coli suspension. Following the transformation procedure, the cells were spread on LB plates containing ampicilin (50 µg ml<sup>-1</sup>) and incubated at 37 °C overnight. The closes were then replated on LB plates containing tetracycline (20 µg ml<sup>-1</sup>). Clones growing on Ap but not Tc were scored as Ap<sup>3</sup>, Tc<sup>3</sup> mutants. Such individual mutant clones were then grown further in LB medium plus ampicillin for preparation of the plasmid DNA contained in these clones. Plasmid DNA was purified either on a small scale (10 ml of culture) by an adaptation of the method of Clewell and Heimski<sup>23</sup> or on a larger scale (11 culture) by a NaCl/SDS lysas procedure followed by a CsCl/ethadrum bromude centrifugation step <sup>23</sup>. DNA sequence analysis of the mutants. Class II mutant plasmids (see text for the definition) were digested with BamHI and SaII restriction enzymes and <sup>32</sup>P-end-labelled at their 5' extremnties with T4 DNA kinase (Bochringer, Mannheim). Strand separation and sequencing were performed according to the method of Maxam and Gilbert<sup>14</sup>.

frequency, provided the cells are exposed to UV before the transformation step. The mutant DNAs isolated from such experiments fall into two classes when analysed by gel electrophoresis: class I mutants defined as in the control experiment, and class II mutants, exhibiting the original size of pBR322 and retaining both BamHI and SalI restriction sites.

The frequency of class II mutants increases with the level of AAF modification and reaches about 3% at the highest level tested (Fig. 2). Note that only the class II mutation frequency is (1) a function of AAF modification and (2) dependent on UV irradiation of the host cell (for the conditions, see Fig. 1 legend). Both these properties indicate that class II mutants, as opposed to class I mutants, are actually induced by AAF adducts and that they require efficient expression of the cellular SOS functions. We, however, also obtained class II mutants, but at a lower frequency, in conditions where the SOS functions were not induced with UV light, tending to support the hypothesis that there is a constitutive level of error-prone repair<sup>13</sup>.

Class II mutants can also theoretically arise from 'non-targeted' mutations involving the SOS repair functions—mutations could occur during replication of the plasmid by the 'error-prone' SOS system, whether or not the plasmid has been chemically modified. In this hypothesis, however, the mutation could take place anywhere along the tetracycline gene and not exclusively in the 6S fragment. In fact, we have not found class II mutants in the pool of transformants obtained in the control experiment (that is, ligation of a non-modified 6S fragment).

Nine class II mutant plasmids were isolated from either the wild-type E. coll strain, AB 1157, or the corresponding uvrA mutant strain, AB 1886. The double BamHI-SalI-digested DNA was <sup>32</sup>P-end-labelled at the 5' extremities and sequenced according to the Maxam and Gilbert technique <sup>14</sup>. The sequence of the wild-type 6S fragment of pBR322 was found to be identical to that published by Sutcliffe <sup>15</sup>.

In all of the nine class II mutants we found a mutation located within the 6S fragment. All the mutants showed a deletion of either a single G·C base pair or a doublet of adjacent G·C-C·G base pairs. Two of these mutants (numbers 35 and 36) also had a second mutation (Table 1). Mutants 34 and 36 both exhibit a -2 deletion within the alternating GCGC sequence at positions 435-438 (deletion of a GC sequence at position 435-436 or 437-438 or a CG sequence at position 436-437). (Numbering starts clockwise from the unique EcoRI restriction site.) Moreover, mutant 33 also exhibits a -2 deletion within a GCGC sequence at positions 548-551. Note that the same 6-nucleotide long sequence, GGCGCC, occurs at the site of mutations 34, 36 and 33. The fact that this mutation has been observed three times suggests that the given sequence is a good candidate for a mutational hot spot. Such a GC deletion in an alternating GC

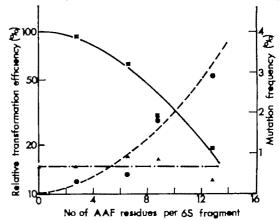

Fig. 2 Relative transformation efficiency and mutation frequencies as a function of the number of AAF residues bound to the 6S fragment. The transformation of E. Coh AB 1157 strain has been performed after UV irradiation of the cells (60 Jm<sup>-2</sup>) as described in Fig. 1 legend. Selection of the transformants was done on LB plates containing ampicillin (50 μg ml<sup>-1</sup>). Mutants were selected by replica plating on LB plates containing tetracycline (20 μg ml<sup>-1</sup>). E. Relative transformation efficiency (log scale), A, class I mutants, Θ, class II mutants

sequence was shown in vivo to be a hot spot for reversion of the mutation, his D3052, in Salmonella by the mutagen 2nitrosofluorene<sup>16</sup>. It is striking that the same type of mutation occurs in both a reversion and forward mutation assay.

As shown in Table 1, four (4, 30, 41 and 45) of the nine mutants show a deletion of a single G residue at position 520 or 521. Note that the four mutants have arisen in different conditions (in two different strains, with or without UV induction of the SOS functions, with very different AAF modification levels). The reason why this particular sequence is a hot spot for mutagenesis is not clear. The possibility that it is a hot spot for the AAF binding reaction itself (the premutational event) is being investigated. Alternatively, it is possible that the processing of the premutational lesions (by the excision repair enzymes for example) is strongly sequence dependent, in which case a hot spot for mutagenesis could arise from the inability of the errorfree repair enzymes to excise the lesion at the given site.

The mechanism by which single GC base pair deletion mutations occur can be tentatively explained on the basis of the insertion-denaturation model<sup>7,10</sup>, whereby the guanine modified at C-8 with the AAF residue is flipped outside the double helix while the AAF residue is inserted between the two neighbouring base pairs. During replication, the AAF-modified guanine, an essentially non-coding base, blocks the replication machinery17. One can hypothesize that SOS functions then become involved at the replication fork which permit this block to be bypassed by allowing the replication to restart at the next base, thus giving rise to the deletion of the AAF-modified guanine residue.

## Mechanism of E. coli RecA protein directed strand exchanges in post-replication repair of DNA

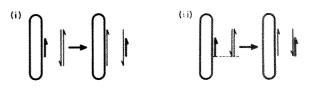

#### Stephen C. West, Era Cassuto & Paul Howard-Flanders

Departments of Molecular Biophysics and Biochemistry, and of Therapeutic Radiology, Yale University, PO Box 6666, New Haven, Connecticut 06511, USA

Escherichia coli mutants carrying recA are both recombination deficient and unable to perform post-replication repair<sup>1,2</sup>. The product of the recA gene regulates the inducible DNA repair functions (the SOS response to DNA damage)<sup>3,4</sup>, and is directly involved in homologous pairing<sup>5-8</sup> and strand exchange<sup>9-12</sup>, two reactions fundamental to recombination and post-replication repair. The filling of post-replication gaps is thought to occur by homologous pairing of the gapped DNA duplex with an intact duplex, followed by cutting of the intact molecule so that sister strand exchanges can take place. Using in vitro systems, we have shown previously that purified RecA protein binds cooperatively to duplex DNA that contains gaps 13, and promotes joint molecule formation (synapsis) between gapped and intact duplexes<sup>7,8</sup>. Moreover, RecA protein promotes a reciprocal exchange of strands between paired DNA molecules 10,12,14. Here, we investigate the mechanism of sister strand exchange thought to occur during post-replication repair. We show that RecA protein initiates strand exchange from a nicked duplex, transferring the 3'-OH terminus at the nick into the single-stranded (ss) region of the gapped molecule. In the presence of ATP, two heteroduplex molecules are formed as RecA protein drives the reciprocal exchanges in one direction starting at the site of the original crossover.

The assay for strand exchange involves the incubation of 32Plabelled duplex restriction fragments with unlabelled circular ssDNA, to which we have annealed a short complementary <sup>3</sup>H-labelled fragment (Fig. 1a(i)). The annealed substrate

#### a DNA substrates that initiate strand exchange

#### b DNA substrates that do not exchange strands

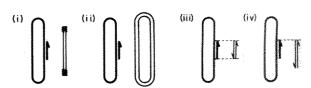

Fig. 1 DNA substrates used in RecA protein-mediated strand exchange tests. The 3' terminus of each strand is indicated with a half arrow. a(i), Annealed substrate (ΦX (+)ssDNA with a 503nucleotide Aval-Avall (-)annealed fragment) and a homologous linear duplex (872-base pair (bp) HaeIII fragment 3) that overhangs both ends of the annealed fragment. These substrates were used in the experiment of Fig. 2. (ii), Homologous duplex that overhangs one end of the annealed fragment (Fig. 2d in ref. 14). Exchange is dependent on polarity and is observed only if the overhanging (-)strand of the duplex has a 3' terminus<sup>14</sup>. b, Strand exchange does not occur when: (i), the duplex has non-homologous ends (wavy lines) (Fig. 2b in ref. 14); (ii), the duplex has no free end (Fig. 1 V in ref. 10); (iii) the duplex is flush-ended with the annealed fragment (Fig. 1 IV in ref. 10); (iv), the (-)strand of the one overhanging end of the duplex has a 5' terminus (Fig. 2c in ref. 14).

sedimented faster through neutral sucrose than the short duplex fragments (Fig. 2a). However, incubation in the presence of RecA protein caused an exchange of labelled strands, heteroduplex DNA being formed as 57% of the <sup>3</sup>H-labelled annealed fragments were transferred from the ssDNA in exchange for  $\sim$ 50% of the (-)strands of the duplex (25% of total  $^{32}$ P label). These results, shown in Fig. 2b, indicate that RecA protein promotes reciprocal strand exchanges to form two heteroduplex molecules and are described in more detail elsewhere 10,14

We wished to test two aspects of RecA protein-mediated strand exchange in relation to the proposed mechanism of post-replication repair<sup>14</sup>. First, does RecA protein initiate strand exchange at a nick in an intact duplex, so transferring a complementary strand into the single-stranded region of a homologous gapped duplex, and second, does RecA protein drive the reciprocal strand exchange in a polar way from the site of the initial crossover. To test these points we constructed the DNA substrates shown in Fig. 3 (i) and (ii).

In a control experiment we reacted the substrates shown in Fig. 3 (i) with RecA protein. The annealed substrate is the same as that used in Fig. 2; it contains both duplex and single-stranded regions and is therefore similar to a gapped duplex. The linear duplex has one end flush with the AvaI end of the annealed fragment and the opposite end is non-homologous with  $\Phi X$  DNA. We have shown previously  $^{10.14}$  that duplexes with ends non-homologous or flush with the annealed fragment do not initiate strand exchanges (Fig. 1b (i) and (iii)). As expected with a duplex of this structure, strand exchanges were not observed (Fig. 3a).

The experiment was then repeated using a similar linear duplex that had been nicked at the BamHI site in one or the other of the two strands (indicated with an arrow in Fig. 3 (i)). Assuming that the site-specific nicking occurred with the same efficiency in both strands, we estimated that  $\sim 20\%$  of the linear fragments used in the reaction mixture contained nicks in the (-)strands. We therefore used an excess of linear duplexes in these experiments. Efficient strand exchanges took place, 41% of the annealed framents being transferred (Fig. 3b).

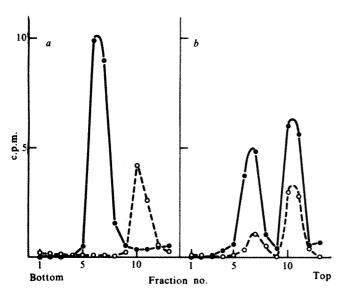

Fig. 2 Neutral sucrose sedimentation profiles showing strand exchanges between the DNA molecules of Fig. 1a(i). Sedimentation is to the left. a, Annealed substrate (unlabelled ΦX ssDNA with <sup>3</sup>H-labelled Aval-AvaII annealed fragment) with <sup>32</sup>Plabelled  $\Phi X$  HaeIII 3 linear duplex; b, same as a but with RecA protein. Annealed substrate, duplex fragments and RecA protein were added where indicated at  $1.75 \,\mu\text{M}$ ,  $0.42 \,\mu\text{M}$  and  $5 \,\mu\text{M}$ , respectively. Duplex fragments and the annealed substrate were prepared as described previously 10 except that AvaI and AvaII were used to digest the <sup>3</sup>H-labelled ΦX RFI DNA for annealed substrate preparation. RecA protein was purified as described elsewhere 13. The standard reaction mixture contained in a total volume of 100  $\mu$ l, 20 mM Tris-HCl pH 7.5, 25 mM MgCl<sub>2</sub>, 2 mM dithiothreitol, 2 mM ATP and 100  $\mu$ g ml<sup>-1</sup> bovine serum albumin. Incubation was for 45 min at 37 °C. The reaction was stopped by the addition of 50 mM EDTA, and proteins were removed by treatment with 200 µg ml<sup>-1</sup> proteinase K and 1% SDS<sup>10</sup>. Centrifugations were through 5 ml of 5-20% neutral sucrose in a Beckman SW 50.1 rotor at 45,000 r.p.m. for 180 min at 4 °C. Fractions collected from the gradients were counted for radioactivity in Formula 963 scintillation fluid (NEN). lacktriangle,  $^3H$ ,  $\times 10^{-2}$ ;  $\bigcirc$ ,  $^{32}P$ ,

Table 1 Tests for strand exchange between the annealed substrate and a nicked duplex: the effect of nick closing by T4 DNA ligase

Linear duplex a, Nicked chimaeric duplex (Fig. 3 (i))	Ligase	RecA +	% Strand exchange 33
b, Same as a	+	+	8
c, Homologous duplex (ΦΧ HaeIII-AvaI)	-	+	40
d, Same as c	+	+	40

The reactions described here were carried out in two stages, ligation and then strand exchange. In the first, the duplex fragments, either 0.42 μM ΦX linear HaeIII-AvaI or 3.15 μM nicked pSW1 HaeII-Aval, were incubated for 20 min at 25 °C with or without 8×10 of T4 DNA ligase (BRL) in 100 µl of 50 mM Tris-HCl pH 7.8, 10 mM MgCl<sub>2</sub>, 2 mM dithiothreitol, 1 mM ATP and 50 µg ml 1 bovine serum albumin. The reaction mixtures were heated for 5 min at 60 °C to inactivate the ligase, and cooled to ice temperature. In the second stage, we added 100  $\mu$ l of buffer containing 20 mM Tris-HCl pH 7.5, 25 mM MgCl<sub>2</sub>, 2 mM dithiothreitol, 2 mM ATP, 100  $\mu$ g ml<sup>-1</sup> bovine serum albumin, 1.75 µM of the annealed substrate (Fig. 1a (i)) and 5 µM RecA protein, and incubated the mixtures for 45 min at 37 °C. Proteins were removed from the DNA and the reaction products sedimented through neutral sucrose as described in Fig. 2 legend. The linear duplex  $\Phi X$  HaeIII-AvaI was prepared as described previously 14 and the nicked duplex was prepared as in Fig. 3 legend. The per cent strand exchange was calculated from the amount of total <sup>3</sup>H-labelled annealed fragments that were displaced from the annealed substrate. The concentration of DNA ligase used here was predetermined as an amount sufficient to ligate 80% (as determined by alkaline sucrose sedimentation) of the nicks in 100 µl of 3.5 µM pBR322 DNA. This DNA had been nicked by pancreatic DNase I in the presence of ethidium bromide. The conditions of the experiment did not result in any dimerization of the linear duplex fragments (detected by polyacrylamide gel electrophoresis).

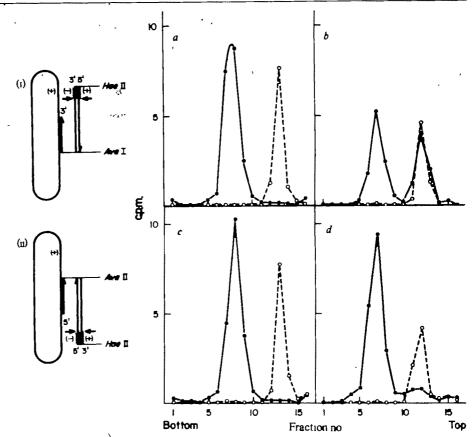

To confirm that strand exchanges were indeed initiated from the nick in the duplex molecule, we incubated the nicked DNA with T4 DNA ligase just before the addition of RecA protein and the annealed substrate to the reaction mixture. RecA protein did not promote strand exchanges when the nicks were preligated (Table 1b), whereas incubation of an identical reaction mixture without DNA ligase resulted in efficient strand exchanges (Table 1a). In a control to test whether RecAmediated strand exchanges might be inhibited by the presence of DNA ligase, we examined the effect of ligase on a similar reaction between the annealed substrate and a linear duplex. The results in Table 1c and d show that strand exchanges occurred with the same efficiency in the absence or presence of DNA ligase, indicating that no inhibitory factors were present in the reaction mixture.

These results show that strand exchanges take place efficiently between an annealed substrate and a duplex nicked at the BamHI site (Fig. 3 (i)). The nick was essential for the initiation of strand exchanges.

It is interesting that the 3'-terminal base of the strand transferred from the nicked duplex is derived from a molecular linker inserted into the plasmid pSW1 during construction of the chimaeric plasmid  $^{14}$ . The terminus ending CCG-3'OH is transferred to the complementary  $\Phi X$  sequence... GGT....5' to form a G/T single nucleotide mismatch (sequence from Sanger et al. 15). Thus, although this single nucleotide mismatch at the 3' terminus does not block strand exchange, we have shown previously that a non-homologous terminal region of 150 bases is sufficient to block the reaction  $^{14}$ .

To test whether strand exchanges from a nick are driven in a polar way, we incubated the DNA substrates shown in Fig. 3 (ii) with RecA protein. These substrates are similar to those described above (Fig. 3 (i)) except that the BamHI nick of the duplex is in a different position relative to the annealed fragment. The results shown in Fig. 3d indicate that this nicked duplex is inefficient at strand exchange,  $\sim$ 9% of the <sup>3</sup>H-labelled annealed fragments being transferred. In the absence of a nick,

Fig. 3 Neutral sucrose sedimentation profiles to show initiation of strand exchange by the nicked duplexes shown in (i) and (ii). a, Annealed substrate with intact Haell-Apal duplex DNA and RecA protein. b, Same as a but the duplex was nicked at the BamHI site. c, Annealed substrate with intact AvaII-HaeII duplex DNA and RecA protein. d, Same as c but the duplex was nicked at the BamHI site. In substrates (i) and (ii), nonhomologous DNA is indicated by a wavy line, and the site of nicking by BamHI/EtBr is arrowed. In all reactions, the annealed substrate, duplex fragments and RecA protein were present at 1.75 µM, 3.15 µM and 5 µM, respectively. Incubation and sedimentation were as described in Fig. 2 legend. Duplex fragments were prepared by digesting pSW1 form I <sup>32</sup>P-labelled DNA with *Hae*II and fragment 3 was purified <sup>14</sup>. The fragment was extracted with isobutanol to remove ethidium bromide and digested with either AvaI or AvaII. The larger fragments in each case were purified and extracted with phenol and isobutanol. Nicked duplex fragments were prepared in the same way from pSW1 DNA that

was nicked by Bami in the presence of ethicium bromide<sup>21</sup>. As 80% of the closed circles were nicked in the BamHI/EtBr reaction (determined by agarose gel electrophoresis and alkaline sucrose sedimentation), and as the single nick could be in either strand at one of the two BamHI sites, we estimate that 20% of the duplexes contained nicks in the (-)strand at the BamHI site.  $\bullet$ ,  ${}^{3}$ H,  $\times 10^{-2}$ ;  $\circ$ ,  ${}^{32}$ P,  $\times 10^{-2}$ .

we found the normal background (<5%), indicating that no strand exchange had taken place (Fig. 3c). Comparison of the data presented in Fig. 3b and d indicates that RecA protein shows a strong directional bias for the extension of the heteroduplex region from the nick. As the polarity of each DNA strand is known from the DNA sequence 15, the directionality of

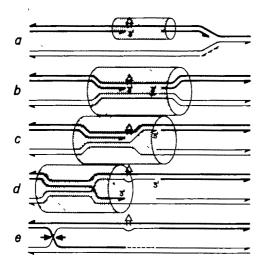

Fig. 4 Model for the repair of a post-replication gap by RecA protein-mediated sister strand exchanges. RecA protein molecules (shaded area) bind at the post-replication gap (a) promoting homologous pairing (b). The intact molecule is nicked by the cutting in trans activity (b) and the 3' terminus of the nicked strand is transferred by RecA protein into the post-replication gap (c). Directional strand transfer driven by RecA protein results in the reciprocal transfer of the 3' terminus of the gapped strand to produce a crossed strand exchange or Holliday structure (d). The crossed strand exchange is cut leading to completion of the repair (e).

RecA-driven exchanges can be determined. The efficient strand exchange initiated by the nicked duplex (Fig. 3 (i)) occurs by transfer of the free 3'-OH terminus at the nick of the complementary strand into the single-stranded region of the annealed substrate. The heteroduplex region is then extended by RecA protein transferring strands in a 3' to 5' direction (relative to the transferred strand). The polarity of strand exchange shown here is therefore similar to those involving exchanges initiated by a linear duplex14,16,17

The experiments described here suggest a way in which RecA protein may exchange DNA strands in post-replication repair. As shown in Fig. 4, DNA polymerase moving in a 3' to 5' direction along the template strand is blocked at a pyrimidine dimer and reinitiates synthesis further along the chain. The daughter strand is therefore terminated with a 3'-OH at the position of the dimer (Fig. 4a). The resulting ssDNA activates the RecA protease 18, triggering the SOS response and increasing the synthesis of RecA protein in readiness for pairing with the intact sister duplex (Fig. 4b). Pairing may occur at the site of the gap with the single-stranded region of the gapped molecule wound in the major groove of the duplex. Once homologous contacts are established, a cutting in trans enzyme may nick the intact sister duplex at a site opposite the gap 19 (Fig. 4b). The nick enables RecA protein to transfer the 3'-OH terminus of the nicked strand into the gap, thus providing an intact strand complementary to the one containing the dimer (Fig. 4c). The strand exchange reaction is therefore initiated in a threestranded way as RecA protein drives branch migration and heteroduplex formation beyond the dimer. The 3'-OH terminus of the gapped strand is also transferred, producing a crossed strand exchange (Fig. 4d). From that point on, the four strands are paired and exchanged as described previously10 to produce duplex molecules. Both helices can now be repaired by DNA polymerase I and ligase (Fig. 4e) and completion of repair permits the release of RecA protein and terminates the SOS response. The resulting crossed strand exchange is presumably

resolved by a further recombination enzyme, perhaps similar to the phage T4 gene 49 nuclease<sup>20</sup>. The final structure retains the pyrimidine dimer, but now has an intact complementary strand and can be repaired by excision enzymes

It is well established that the structure 1,2 as well as the stability of the DNA duplex is affected by supercoiling. Supercoiled DNA has been shown to possess increased stability and is thus characterized by an elevated melting temperature as well as a broader melting transition. Thermal melting analysis has been the most widely used method for studying the structural and dynamic properties of complex DNA species. Here we report a remarkable attribute of supercoiled DNA, that the width of the melting transition of superhelical DNA does not depend appreciably on

the relative stabilities of its A·T and G·C base pairs.

It has been shown earlier<sup>3.4</sup> that superhelical DNA (DNA I) melts at higher temperatures and over a broader temperature range than do open circular molecules (DNA II). These experiments were carried out in conditions such that the stabilities of the A·T and G·C base pairs were substantially different. To eliminate the possible influence of this factor on the melting process, we performed the thermal denaturation of DNA in experimental conditions in which the A·T and G·C base pairs were of equal stability by dissolving the DNA in a concentrated solution of tetraethylammonium bromide (TEA)5

Figure 1a shows the integral and differential melting curves of the replicative form of phage  $\Phi X174$  DNA in a solution containing 3 M TEA (the sample was a 10:1 mixture of DNA I and DNA II). The step at 58 °C in the melting curve (the sharp peak in the differential curve) corresponds to the melting of DNA II. Its melting range is less than 1 °C wide, thus indicating that the thermal stabilities of A T and G C base pairs are approximately equal5,

The melting of DNA I seems to be quite different. Its first intriguing feature is the width of the denaturation range. Melting is appreciable at 60 °C but even at 95 °C ~10% of the base pairs are still in the native state. Over the temperature range 60-90 °C the derivative  $d\theta/dT$  increases and reaches  $1/25\,^{\circ}\mathrm{C}$  at the transition midpoint ( $\theta = 1/2$ ).

Figure 1b shows the melting curves of the same sample as in Fig. 1a, but in a solution containing 7.3 M NaClO<sub>4</sub> (conditions in which the difference in stability between A·T and G·C base pairs,  $T_{GC} - T_{AT}$  is ~56 °C)<sup>7</sup>. Here DNA II melting occurs over a broad (8-10 °C) range, and the differential curve shows a resolved fine structure.

In contrast, the melting profile of DNA I remains practically unchanged, and the derivative  $d\theta/dT$  at the transition midpoint has the same value of 1/25 °C. Moreover, the temperature difference between the melting midpoints of DNA I and DNA II is the same (25 °C) in both experimental situations (Fig. 1a, b). These findings elucidate the fundamental property of superhelical DNA-that, in contrast to linear DNA or DNA II, its melting is insensitive to the value of  $T_{\rm GC}-T_{\rm AT}$  and, therefore, to the nucleotide composition heterogeneity.

A slight increase of absorbance before the melting of DNA II can be seen in both Fig. 1a and b. In Fig. 1a this effect is not superimposed on the melting of DNA II and its magnitude can be evaluated ( $\theta \approx 0.05$ ); it corresponds roughly to the degree of denaturation necessary to remove all superhelical turns (as reported elsewhere<sup>8</sup> the superhelical density of ΦX174 DNA is 0.063). Thus, the increase in absorbance could be attributed to early melting of DNA I3. However, this effect is of the same order of magnitude as the baseline instability of the instrument, further investigation is necessary.

The theory of the 'helix-coil' transition in polynucleotides without topological constraints (linear or open circular DNAs) is

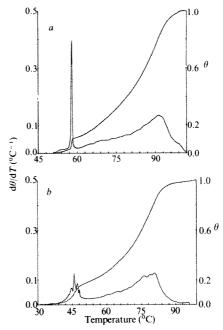

Fig. 1 The integral and differential melting curves of the replicative form of phage  $\Phi$ X174 DNA; a, in the presence of 3 M TEA  $(T_{GC} - T_{AT} \approx 0 \, ^{\circ}\text{C})^{5.6}$ , b, in the presence of 7.3 M NaClO<sub>4</sub>  $(T_{GC} - T_{AT})$  $(T_{\rm GC}-T_{\rm AT}\approx0~{\rm ^{\circ}C})^{5.6}$ , b, in the presence of 7.3 M NaClO<sub>4</sub>  $(T_{\rm GC}-T_{\rm AT}\approx56~{\rm ^{\circ}C})^{7}$ . A 120-µl aliquot of solution contained 10-12 µg ml<sup>-1</sup> DNA (10:1 mixture of DNA I and DNA II), 10 mM phosphate buffer pH 8.0 and the concentration of TEA or NaClO<sub>4</sub> indicated above. The melting curves were registered on a Carry 218 spectrophotometer, equipped with a specially constructed sample holder with a facility for temperature control. Temperature scanning rate was  $0.2\,^{\circ}\text{C}$  min $^{-1}$ . The melting curves were differentiated using a Hewlett-Packard 9830A computer.

well developed, and excellent agreement with experimental data has been achieved for such molecules7. However, the abovementioned features of the melting of covalently closed DNA cannot be explained within the framework of this theory. An adequate explanation should be based on a correct account of the effect of topological constraints on the thermodynamical properties of DNA.

Despite the disruption of the double helix, the topological state of DNA I (linking number of the strands, Lk) remains invariable. That leads to an excess of Lk and therefore to extra free energy in DNA I compared with DNA II at the same degree of denaturation  $(\Delta Lk \sim \theta)$ .

When DNA is treated as a thin ribbon (an approximation which seems to be reasonable at small degrees of denaturation), a part of Lk can be isolated (writhing, Wr) which is determined by the spatial configuration of DNA duplex axis only. Then the difference (Lk - Wr) will account for the twist (Tw) of the ribbon9. The extra free energy of DNA I within the melting interval is a function of both Wr and Tw. These values cannot be precisely estimated at present. In this situation a heuristic approach seems to be reasonable. In the most advanced theoretical work on the problem<sup>10</sup> it was assumed that the strands in the melted region remain twisted to the same extent as before denaturation. Thus, the possible contribution of Wr to Lk was ignored. According to this model, the melting range for DNA I should be 2-3 times larger than that for DNA II<sup>10</sup>. The latter factor fits the experimental data when the value of  $T_{\rm GC} - T_{\rm AT}$  is large. However, for  $T_{\rm GC} \simeq T_{\rm AT}$  there is marked disagreement between calculated and experimentally obtained values for the width of melting range

We consider the failure of the model to be due to the neglect of the possible contribution of Wr to Lk. Because of the enhanced flexural 'softness' of partially melted DNA the latter can be significant. The theoretical treatment of the model, allowing for such a possibility, will be reported elsewhere.

## Polycythaemia- and anaemia-inducing strains of spleen focus-forming virus differ in post-translational processing of envelope-related glycoproteins

#### Sandra K. Ruscetti. John A. Feild & Edward M. Scolnick

Laboratory of Tumor Virus Genetics, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

A virus preparation was isolated by Friend which produced a rapid erythroblastosis in certain strains of mice1. Although the original virus preparation induced a slight anaemia in the terminal stages of the disease, other variants, derived from various in vivo and in vitro passages of the original virus, were associated with polycythaemia<sup>2,3</sup>, and the different viruses were accordingly classified as FVA (Friend virus anaemia-inducing) or FVP (Friend virus polycythaemia-inducing). Another important difference between the two strains is that whereas FVP induces in infected mice cells that are capable of forming

colonies in vitro in the absence of erythropoietin4.5, colonies formed by cells derived from FVA-infected mice are erythropoietin dependent<sup>6-9</sup>. Differences were also noted in the amount of haemoglobin present in erythroid bursts produced after in vitro infection of haematopoietic cells with FVP or FVA<sup>22</sup>. Both FVA and FVP virus stocks have been shown to consist of at least two different viruses: the spleen focus-forming virus (SFFV<sub>P</sub> or SFFV<sub>A</sub>), a replication defective virus; and the Friend murine leukaemia virus (F-MuLV), a replication competent virus which acts as a helper virus for replication of the defective SFFV<sup>6,23</sup>. Here, in an attempt to correlate differences in the biological effects of the SFFVs derived from FVP and FVA stocks with biochemical properties of proteins encoded by them, we have compared the post-translational processing of the envelope glycoproteins encoded by these viruses, and have found both qualitative and quantitative differences in the processing of the envelope glycoproteins of the two virus stocks.

Although the genomes of the SFFVs derived from FVP and FVA stocks differ slightly<sup>10</sup>, both encode similar primary translational products—a 45,000 molecular weight (M<sub>r</sub>) gag-related protein (p45gag) and a 52,000-Mr envelope-related glycoprotein (gp52<sup>env</sup>)<sup>6,11,12</sup>. Studies with subgenomic fragments of molecularly cloned SFFV<sub>P</sub> have shown that the biological activity of SFFV requires<sup>13</sup> the gene encoding gp52<sup>env</sup>, but not that encoding p45gag. Differences in the tryptic peptides of gp52env exist among different strains of SFFV<sub>P</sub> (S.K.R., unpublished data) as well as between the SFFVs derived from FVP and FVA stocks6. However, these differences have not been correlated with the different biological effects of SFFV<sub>P</sub> and SFFV<sub>A</sub>.

When NRK fibroblasts were nonproductively infected with the Lilly-Steeves strain of SFFV<sub>P</sub> (ref. 14) and the major product of the *env* gene detected by pulse-labelling the cells with <sup>35</sup>S-methionine and immune precipitating with specific anti

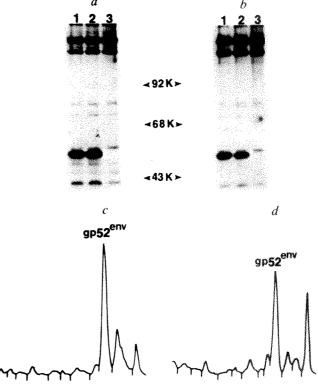

Fig. 1 Immune precipitation of <sup>35</sup>S-methionine-labelled SFFV<sub>P</sub> and SFFV<sub>A</sub> cytosol proteins. Fibroblasts nonproductively infected with either SFFV<sub>P</sub> (a) or SFFV<sub>A</sub> (b) were labelled for 30 min with  $^{35}$ C and  $^{35}$ C. S-methionine and then immune precipitated with goat anti-Rauscher MuLV gp70 serum (lanes 1), a goat antiserum specific for the gp70 of MCF murine leukaemia viruses (lanes 2), or normal goat serum (lanes 3). Precipitates were then electrophoresed on 7% SDS-polyagralamida and % SDS-polyacrylamide gels and exposed to X-ray film as previously described 12. c, d Represent densitometer scans of lanes 1 in a and b, respectively.

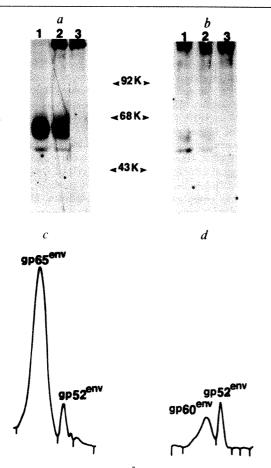

Fig. 2 Immune precipitation of  ${}^{3}$ H-galactose-labelled SFFV<sub>p</sub> and SFFV<sub>A</sub> cytosol proteins. Fibroblasts nonproductively infected with either SFFV<sub>p</sub> (a) or SFFV<sub>A</sub> (b) were labelled with  ${}^{3}$ H-galactose and then immune precipitated with goat anti-Rauscher MuLV gp70 serum (lanes 1), a goat antiserum specific for the gp70 of MCF murine leukaemia viruses (lanes 2), or normal goat serum (lanes 3). The precipitates were processed as described in Fig. 1 legend. c, d Represent densitometer scans of lanes 1 in a and b, respectively.

gp70 sera as previously described<sup>12</sup>, a  $52,000-M_r$  protein (gp52<sup>env</sup>) was specifically precipitated (Fig. 1a, lanes 1, 2). Post-translational processing of the SFFV envelope proteins and expression of these proteins at the cell surface were then studied by pulsing the cells with <sup>3</sup>H-galactose<sup>15</sup> or labelling the cells with <sup>125</sup>I in the presence of lactoperoxidase<sup>12</sup>, respectively, before immune precipitation with specific antisera. Proteins precipitated in each case were visualized by autoradiography after electrophoresis on SDS-polyacrylamide gels. When SFFV<sub>P</sub>/NRK cells were labelled with <sup>3</sup>H-galactose, gp52<sup>env</sup> and 65,000-M<sub>r</sub> glycoprotein (gp65<sup>env</sup>) were detected, indicating that the gp52<sup>env</sup> is processed by the addition of complex carbois processed by the addition of complex carbohydrates to a higher molecular weight form (Fig. 2a, lanes 1, 2). gp65<sup>env</sup> was detected on the cell surface when cells were labelled with <sup>125</sup>I in the presence of lactoperoxidase (Fig. 3a, lanes 1, 2). This seems to be a common pathway for SFFV<sub>P</sub> envelope proteins, as two other polycythaemia-inducing strains of SFFV, the Mirand and Axelrad strains, synthesize 62-68,000-M<sub>r</sub> envelope glycoproteins which can be detected after metabolic labelling of nonproducer cells with <sup>3</sup>H-galactose<sup>15</sup> face labelling with 125 I (S.K.R., unpublished data).

Cells nonproductively infected with SFFV derived from an anaemia-inducing stock of Friend virus<sup>11</sup> also synthesized a 52,000-M<sub>r</sub>, glycoprotein that could be labelled with <sup>35</sup>S-methionine and immune precipitated with anti-gp70 sera (Fig. 1b, lanes 1, 2). When SFFV<sub>A</sub> nonproducer cells were labelled with <sup>3</sup>H-galactose, gp52<sup>env</sup> but no gp65<sup>env</sup> was detected (Fig. 2b, lanes 1, 2). However, the cells contained a low amount of a 60,000-M<sub>r</sub>, glycoprotein that was precipitable with anti-gp70 sera. When we attempted to label surface proteins

with <sup>125</sup>I and lactoperoxidase, no envelope-related proteins were detected on the surface of SFFV<sub>A</sub> nonproducer cells (Fig. 3b, lanes 1, 2).

The differences in the levels of processed envelope glycoproteins in SFFV<sub>P</sub> and SFFV<sub>A</sub> nonproducer cells were quantified by scanning films of the gels with a densitometer. Cells nonproductively infected with either expressed almost equivalent levels of gp52<sup>env</sup> (Fig. 1, 2, panels c, d) but SFFV<sub>P</sub> nonproducer cells expressed eightfold higher levels of any high molecular weight, galactose-containing envelope glycoprotein than did SFFV<sub>A</sub> nonproducer sells (Fig. 2c, d).

Differences in processing of SSFV<sub>P</sub> and SFFV<sub>A</sub> gp52<sup>env</sup> were also detected *in vivo*. Spleens of mice infected with either the FVP complex (SFFV<sub>P</sub> pseudotyped with F-MuLV) or the FVA complex (SFFV<sub>A</sub> pseudotyped with F-MuLV) were labelled with either <sup>35</sup>S-methionine or <sup>3</sup>H-galactose and immune precipitated with anti-gp70 sera. F-MuLV and SFFV envelope glycoproteins could be distinguished from each other using a MCF-specific antiserum that will precipitate SFFV, but not F-MuLV, envelope glycoproteins<sup>12</sup>. As shown in Fig. 4, spleens from mice infected with either virus expressed equivalent amounts of SFFV gp52<sup>env</sup> (Fig. 4a, lanes 1, 2; b, lanes 1, 2) but differed in the levels of the processed form of gp52<sup>env</sup> detected by labelling with <sup>3</sup>H-galactose (Fig. 4c, lanes 1, 2; d, lanes 1, 2). Equivalent levels of <sup>35</sup>S-methionine- and <sup>3</sup>H-galactose-labelled F-MuLV-encoded envelope proteins were detected in spleens from animals infected with either virus.

Our results indicate that the processing of the envelope glycoproteins encoded by the SFFVs derived from FVP and FVA stocks differs both quantitatively and qualitatively. The gp52<sup>env</sup> encoded by three different strains of SFFV<sub>P</sub> is processed to a galactose-containing 65,000- $M_r$  glycoprotein which eventually appears on the cell surface, whereas most of the gp52<sup>env</sup> encoded by SFFV<sub>A</sub> is not further processed to a higher molecular weight, galactose-containing form and cannot be detected on the cell surface. Cells nonproductively infected with the Rauscher strain of SFFV, another anaemia-inducing erythroblastosis virus<sup>16</sup>, show similar differences in envelope glycoprotein processing and transport.

A variety of membrane glycoproteins have been shown to contain a signal peptide at their amino terminus that is believed to be necessary for proper processing of the glycoproteins and transport to the cell surface<sup>17-19</sup>. Although such a signal peptide has not been identified for any of the envelope proteins of RNA tumour viruses, one could postulate that the difference in the processing of SFFV<sub>P</sub> and SFFV<sub>A</sub> envelope proteins is due to a

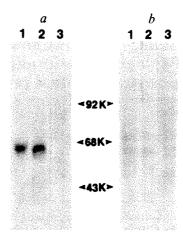

Fig. 3 Immune precipitation of  $^{125}$ I-labelled SFFV<sub>P</sub> and SFFV<sub>A</sub> cell-surface proteins. The surface proteins of cells nonproductively infected with either SFFV<sub>P</sub> (a) or SFFV<sub>A</sub> (b) were labelled with  $^{125}$ I in the presence of lactoperoxidase and then immune precipitated with goat anti-Rauscher MuLV gp70 serum (lanes 1), goat antiserum specific for the gp70 of MCF murine leukaemia viruses (lanes 2), or normal goat serum (lanes 3). The precipitates were processed as described in Fig. 1 legend.

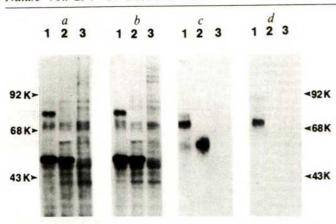

Fig. 4 Immune precipitation of spleen cell extracts from mice infected with either the FVP or FVA complex. Spleen cells from BALB/c mice infected 21 days previously with either 4×10 focus-forming units of F-MuLV/SFFV<sub>P</sub> (a, c) or  $1-2 \times 10^4$  focusforming units of F-MuLV/SFFV<sub>A</sub> (b,d) were labelled with either <sup>35</sup>S-methionine (a,b) or <sup>3</sup>H-galactose (c,d) and then immune precipitated with goat anti-Rauscher MuLV gp70 serum (lanes 1), a goat antiserum specific for the gp70 of MCF murine leukaemia viruses (lanes 2), or normal goat serum (lanes 3). Precipitates were processed as described in Fig. 1 legend.

mutation in the gene encoding the signal peptide of the SFFVA gp52env, resulting in defective processing and failure to transport the protein to the cell surface. Consistent with such a hypothesis, oligonucleotide fingerprinting data show that the only detectable differences in the RNAs of FVP and FVA strains of SFFV are six oligonucleotides at the extreme 5' end of the RNA and two oligonucleotides at the 5' end of the envelope gene that are missing in SFFV<sub>P</sub> RNA as well as the RNAs of F-MuLV and Friend MCF virus 10. As the envelope message of RNA tumour viruses has been shown to contain sequences spliced from the 5' end of the genome<sup>20,21</sup>, a signal sequence for the envelope gene of SFFV could be present in either of the areas of the SFFV genome which are different in SFFV<sub>P</sub> and SFFV<sub>A</sub>.

The differences in the processing of envelope glycoproteins encoded by SFFV<sub>P</sub> and SFFV<sub>A</sub> may be responsible for the different biological activities of these viruses. For example, the concentration of gp65<sup>env</sup> on the cell surface could be important in determining the ability of proliferating cells to differentiate in the presence of various concentrations of erythropoietin. Alternatively, differences in biological activity and glycosylation could be independent consequences of a difference in the primary amino acid sequence of the envelope glycoproteins. Analysis of the biological effects of SFFV<sub>P</sub> in conditions where glycoprotein processing is inhibited, sequencing of the envelope genes of molecularly cloned DNAs from SFFV<sub>P</sub> and SFFV<sub>A</sub>, and generation of mutants of molecularly cloned SFFV<sub>P</sub> that biologically resemble SFFVA should help to establish a relationship between the observed differences in glycoprotein processing and the different biological effects of these SFFV variants.

### Haemolysin contributes to virulence of extra-intestinal E. coli infections

Escherichia coli is the predominant facultative microorganism isolated from the gastrointestinal tract of man and is the most common enteric organism causing extra-intestinal infections in man, particularly of the urinary tract, peritoneum and blood 1,2. It is likely that a consortium of virulence factors is responsible for the initiation and severity of extra-intestinal E. coli infections. Properties reported to be associated with the virulence of such infections include haemolysin production3, K1 antigen production<sup>4,5</sup>, various O antigens<sup>5</sup> and Fe sequestration6. For example, it has long been recognized that the ability to lyse erythrocytes is a phenotype more common to E. coli strains isolated from infections than those found in normal faeces 3,7-9. It is not clear whether the haemolysin per se is a virulence determinant. However, here we report that an isolated DNA sequence encoding haemolysin, added by recombinant DNA technology to avirulent non-haemolytic faecal isolates of E. coli, results in strains having enhanced virulence as measured in an experimental rat peritonitis model.

Several laboratories have demonstrated that the haemolysins commonly seen among animal faecal isolates of E. coli are encoded by transferable plasmids 10-12. There is evidence that these large plasmids confer virulence when transferred to avirulent strains of E. coli12. However, it is not known whether the haemolysin itself or another unrecognized plasmid-mediated gene is responsible for this virulence phenomenon. Goebel and co-workers have demonstrated using DNA · RNA hybridization that plasmid-mediated haemolysin gene sequences are generally homologous with one another<sup>13</sup>. However, we have found that the haemolysin gene(s) of human E. coli clinical isolates most often resides on the bacterial chromosome14 Recently, chromosomal and plasmid-encoding haemolysin genes have been shown to share regions of DNA sequence homology, suggesting a common origin15

We have previously shown 14 by bacterial mating experiments that the haemolysin locus of the E. coli J96 isolate that causes human urinary tract infection resides on the bacterial chromosome. By cosmid cloning16, we have constructed a library of gene sequences of this organism in E. coli K-12. From a haemolytic E. coli K-12 clone we have identified and subcloned an 11.7-kilobase (kb) SalI restriction endonuclease DNA fragment encoding haemolysin and introduced this DNA fragment into the recombinant DNA vector pACYC184, resulting in a hybrid plasmid, pSF400017. Using the ampicillinresistance transposon Tn1 as a site-specific mutagen<sup>18</sup>, together with an in vitro-derived deletion, we have localized the haemolysin gene sequence to a 7.5-kb portion of pSF400019.

Table 1 Effect of cloned haemolysin gene sequences on rat mortality in experimental intra-abdominal infections

	,	, to open and a second in the certain			
Strain	Source	Haemolytic	Plasmid content	Rat deaths*/rats inoculated	
J198	Human faeces	Name.	Name .	3/32	
WAF 107	Transformation of J198	+	pSF4000	26/28	
WAF 108	Transformation of J198	anaga.	pSF4000::Tn1	0/20	
WAF 111	Transformation of J198	+	pAN202-312	1/19	

A single cryptic plasmid species is present in J198, which is colicin V-negative (ColV<sup>-</sup>).

\* Number of deaths occurring within 7 days after receiving intraperitoneal injection of  $10^7$  colony-forming units of each strain. Inocula were suspended in 10% barium sulphate (w/v)/50% sterile human faeces in brain heart infusion broth. Volume of inoculum in each case was 0.25 ml.

Figure 1 shows a restriction endonuclease fragment map of the haemolysin-encoding region of pSF4000.

The common laboratory strain of E. coli K-12 is considered to be an attenuated organism which cannot be converted to a virulent state by the acquisition of single virulence determinants<sup>4,5</sup>. Therefore, appropriate testing of putative virulence properties should be done in the genetic background of 'wild' strains of E. coli represented by faecal isolates from healthy individuals. From our strain collection, a non-haemolytic 'wild' strain (J198) has proved useful because it can be transformed with plasmid DNA by the CaCl/cold shock technique of Lederberg and Cohen<sup>20</sup>. This particular strain was also attractive for pathogenesis studies because we had found it to be avirulent for rats in an experimental intra-abdominal sepsis

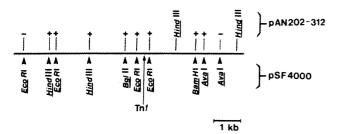

Fig. 1 Physical map of the haemolysin-encoding region of pSF4000. Restriction endonuclease cleavage sites for pSF4000 are shown below the bar. The pSF4000 plasmid was compared with pAN202-312 by restriction endonuclease fragment analysis. pAN202-312 is a recombinant plasmid (vector pACYC184) containing the haemolysin sequence derived from pHly152 (W. Goebel, personal communication); pHly152 was isolated from an E. coli strain found in mouse faeces 13. The restriction sites common to both pSF4000 and pAN202-312 are designated by +. Restriction sites present in pSF4000 but absent from pAN202-312 are indicated by -. Two HindIII sites present in pAN202-312 but absent from pSF4000 are shown above the bar.

model<sup>21</sup>. This model mimics in two stages the disease process of peritonitis and multiple abscess formation seen in humans suffering intra-abdominal sepsis<sup>21</sup>. During the initial acute peritonitis phase in the rat model there is a high mortality rate associated with bacteraemic infections by E. coli or enterococci; here we have focused our attention on the role of putative E. coli virulence factors during this initial phase. The data presented in Table 1 illustrate a significant enhancement in rat mortality when pSF4000 is introduced into J198, which suggests that the haemolysin encoded by pSF4000 is responsible for the lethal behaviour of these strains in this animal model. In support of this, a Tn1 insertional mutant of pSF4000 which no longer confers the haemolysin phenotype does not confer virulence to J198 when present in the same genetic background. The particular Tn 1 insertion used in the virulence studies (see Fig. 1) is in the region which encodes the structural gene for the haemolysin of pHly152 (ref. 22; R.A.W. and S.F., unpublished observations). The observation that the cloned haemolysin derivative pAN202-312 does not confer the same degree of virulence for the rat on J198 as pSF4000 is an interesting finding in view of their apparent sequence homology (Fig. 1). These data illustrate that similarity in phenotype and even close genetic homology may not be sufficient to engender virulence in a particular microorganism. Whether this reflects the structural differences between the 'human' and 'animal' haemolysins or the route by which the infecting microorganism is introduced into a susceptible host awaits further study. Recently, we have observed that another cloned haemolysin of animal origin confers slightly greater virulence than that of pAN202-312 in the rat model (R.A.W., E.P.D. and S.F., unpublished observations). These differences may lead to better understanding of the molecular basis of haemolysin action.

It was of interest to measure the level of virulence of our in vitro-derived pathogen (WAF 107) compared with the original clinical isolate J96 from which the haemolysin gene sequence was taken. It is apparent that the virulence of these two strains are similar quantitatively (Table 2). However, we are hesitant to conclude that acquisition of the haemolysin converts avirulent faecal strains into virulent organisms typical of those found in extra-intestinal infections for two reasons. First, we have noted that the course of infection differs for the two strains. Rats infected with J96 become symptomatic sooner and die earlier than those infected with WAF 107. In most cases, J96-infected rats died 12-24 h post-injection whereas most WAF 107infected rats died between 24 and 36 h after infection. Second, there may be a significant difference in haemolysin gene dosage between clinical isolates and WAF 107 as our haemolysin gene sequence was cloned into a multi-copy plasmid vector. The significance of the dosage effect awaits further experimentation. Table 2 also shows representative LD<sub>50</sub> data for an E. coli K-12 prototroph harbouring the pSF4000 plasmid, which support the observations of other laboratories<sup>4.5</sup> that the virulence of *E. coli* K-12 can be enhanced only slightly by the acquisition of any particular virulence property.

As E. coli infections of the urinary tract and other extraintestinal sites are among the most common of human bacterial diseases, there is wide interest in understanding the precise mechanisms which contribute to the pathogenesis of these infections. Recombinant DNA technology represents a means of measuring the contribution of individual determinants of pathogenicity which are part of a polygenic virulence phenomenon. Although the precise mode of action of E. coli haemolysin in the pathogenesis of infection is still unclear, our data show that it has a significant role.

**Table 2** LD<sub>50</sub> of selected strains in experimental rat intra-abdominal sepsis

Strain	Characteristics	LD <sub>50</sub>
J96	O4, ColV <sup>+</sup> , hly <sup>+</sup> , Hah <sup>+</sup>	$3.5 \times 10^{5}$
J198	O22, ColV, hly, Hah	$>10^{7}$
WAF 107	J198 transformed with pSF4000 DNA*	$1.6 \times 10^{5}$
W1485	K-12 prototroph, ColV, hly, Hah	$>10^{7}$
WAF 109	W1485 transformed with pSF4000 DNA,	$1\times10^7$
	ColV, hly, Hah	

The method of Reed and Muench<sup>23</sup> was used to determine the lethal dose for 50% of the population,  $LD_{50}$ .  $ColV^+$ , colicin V production;  $hly^+$ , haemolytic;  $Hah^+$ , haemagglutination of human erythrocytes.

\* pSF4000 encodes a haemolysin cloned from the J96 background.

## Physiological shear stresses enhance the Ca2+ permeability of human erythrocytes

Fred L. Larsen\*, Sidney Katz\*, Basil D. Roufogalis\*‡ & Donald E. Brooks†

Faculty of Pharmaceutical Sciences\* and Departments of Pathology and Chemistryt, University of British Columbia, Vancouver, British Columbia, Canada V6T 1W5

A membrane-bound  $Ca^{2+}$  pump, capable of extruding  $Ca^{2+}$  at a rate of  $4-30\times 10^{-3}$  mol  $Ca^{2+}$  per l of cells per h in optimal conditions<sup>1</sup>, enables mammalian erythrocytes to maintain a large transmembrane Ca2+ concentration gradient (10-3M outside compared with 10<sup>-6</sup>M inside)<sup>2</sup>. This rate is much greater than the passive  $Ca^{2+}$  influx, estimated<sup>3</sup> to be 6-10×10<sup>-6</sup> mol per l of cells per h. It has been suggested that the apparently large excess capacity of the Ca2+ pump both gives the required sensitivity to a pump incapable of regulating its Ca2+ affinity4 and ensures against Ca2+ toxicity in certain red cell activities<sup>5</sup>. The results presented here, however, show that circulatory shear stresses enhance the Ca<sup>2+</sup> permeability of the membrane, and suggest that greater demands are imposed on the Ca<sup>2+</sup> pump *in vivo* than had been previously thought. We find that the passive permeability to Ca<sup>2+</sup> is increased by up to an order of magnitude and the Ca2+-stimulated ATPase activity is strongly enhanced when red cells are sheared at physiological rates in a rotational viscometer.

It has long been known that the shape and deformability of erythrocytes can influence blood viscosity<sup>6</sup> and hence, in principle, blood flow in the circulation, but effects of fluid shear on cell membrane reactions have been demonstrated only recently<sup>7-9</sup>. Here, examination of the effect of shear rate on Ca<sup>2</sup> uptake into ATP-depleted and ATP-rich human erythrocytes showed a shear-dependent increase in the uptake of <sup>45</sup>Ca<sup>2+</sup> into the cells (Fig. 1), the uptake rate being constant for at least

Shear rate-dependent 45Ca2+ uptake into human erythrocytes. Blood from a healthy volunteer was obtained by venipuncture with a 20-gauge needle in a 10-ml EDTA-vacutainer and tested the same day. Erythrocytes were separated from plasma by centrifugation at 3,000g for 10 min and washed twice in isotonic saline buffered with 20 mM sodium phosphate, pH 7.4. Packed cells were suspended at a haematocrit of ~10% in a solution containing 150 mM NaCl, 5 mM KCl, 15 mM Tris-HCl, 2 mM MgCl<sub>2</sub>, 5 mM iodoacetic acid, 5 mM adenosine and 0.1 mM EGTA at pH 7.4. Half of the sample was left on ice (ATP-rich) and the other half incubated at 37 °C for 3-4 h (ATP-depleted)<sup>16</sup>. Cells were then washed twice in the medium in which the <sup>45</sup>Ca<sup>2+</sup> was to be measured: 150 mM NaCl, in the medium in which the "Ca" was to be heastiful! 130 mM NaCl, 5 mM KCl, 15 mM Tris-HCl, 2 mM MgCl<sub>2</sub> and 2 mM CaCl<sub>2</sub>. "45 CaCl<sub>2</sub> was added (50–70  $\mu$ l of a 0.5 mCi ml<sup>-1</sup> solution) to 10 ml of the erythrocytes suspended at a haematocrit of 39.5–45%. The suspension was sheared in a variable-speed cone-plate Brookfield model LVT "SynchroLectric" viscometer for 15–30 min at various shear rates at 37 °C. The uptake of Ca<sup>2+</sup> into erythrocytes was assessed by a modification of the method reported by Lew and Ferreira<sup>4</sup>. Aliquots (100 µl) of the cell suspension before and after shearing were layered on 200 µl of Ficoll-Paque solution (Pharmacia) in a 400-μl centrifuge tube and spun for 2 min in a Beckman/Spinco 152 microfuge. The extracellular medium (top layer) and the Ficoli-Pacque solution (middle layer) were removed by aspiration from the packed erythrocytes (bottom layer). A very slight red colour in the Ficoll-Pacque solution was observed occasionally, indicating that minimal haemolysis had occurred at the shear rates tested. The walls of the centrifuge tube were wiped dry with a cotton swab and 100 µl of 10% perchloric acid were added to the tube. The tube was capped, vigorously shaken and the resulting precipitate packed by centrifugation for 1 min in the microfuge. Samples of 100 µl of supernatant were placed in 10 ml scintillation fluid (Amersham) and counted in a Beckman LS-3133P scintillation counter. Calcium uptake was expressed per l of cells per h based on the initial haematocrit values of the cell suspensions, as determined with a Clay-Adams micro-haematocrit centrifuge. The results shown are the means ±s.d. of four (ATP-depleted; O) or three (ATP-rich; •) determinations of cells from volunteer 1.

30 min. Figure 1 shows the increase in the rate of calcium accumulation by red cells depleted of their ATP following 15-30 min shear at various shear rates. Even at the lowest shear rate tested (120 s<sup>-1</sup>) there was a significant increase (P < 0.05) in the Ca<sup>2+</sup> taken up by the ATP-depleted erythrocytes compared with control cells which were only gently mixed. The increase in Ca<sup>2+</sup> associated with the cells was due to uptake and not binding to extracellular sites, as washing the cells in 10 times their volume of isotope-free buffer had no effect on the 45Ca<sup>24</sup> uptake measured and ATP-rich erythrocytes showed a much lower <sup>45</sup>Ca<sup>2+</sup> uptake (Fig. 1). The small <sup>45</sup>Ca<sup>2+</sup> uptake seen in ATP-rich cells may reflect exchange with a pool of Ca2+ inaccessible to the pump rather than net uptake, as about 10-15% of the erythrocyte calcium is present in such a compartment 10.11. However, this fraction of  $^{45}\text{Ca}^{2+}$  also seems to increase slightly with shear rate. We estimate this exchangeable pool of Ca2+ to be 4-5 µmol Ca<sup>2+</sup> per 1 of cells, which agrees with previous reports<sup>11</sup>.

The alternative explanation that the Ca2+ uptake into ATPrich cells represents saturation of the Ca<sup>2+</sup> efflux mechanism seems unlikely because the Ca<sup>2+</sup> pump is capable of restoring Ca<sup>2+</sup> to resting levels within a few minutes at 37°C (ref. 12). Therefore, the most likely explanation for the greater 45Ca2 uptake in ATP-depleted than ATP-rich cells is that the ATP-dependent Ca<sup>2+</sup> pump rapidly removes the Ca<sup>2+</sup> taken up when sufficient ATP is present. This explanation is supported by experiments in which active Ca2+ extrusion from ATP-rich cells

‡ To whom correspondence should be addressed

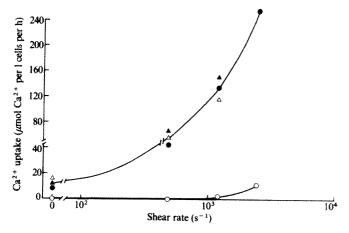

Fig. 2 Effect of La3+ on shear rate-dependent 45Ca2+ uptake into human erythrocytes. The experiments were performed as described in Fig. 1 legend, except that 0.2 mM LaCl<sub>3</sub> was added to the erythrocyte suspension before shearing was begun. A single experiment from volunteer 2 is shown. ATP-rich cells in the absence of La<sup>3+</sup> ( $\bigcirc$ ) and in the presence of 0.2 mM La<sup>3+</sup> ( $\bigcirc$ ); ATP-depleted cells in the absence of La<sup>3+</sup> ( $\triangle$ ) and in the presence of 0.2 mM La3+ (A).

was blocked with La3+ (Fig. 2), which has previously been shown to abolish the active Ca<sup>2+</sup> pump in resealed ghosts<sup>13</sup> and intact cells<sup>14</sup> without blocking the passive Ca<sup>2+</sup> permeability<sup>15</sup>. In the presence of 0.2 mM lanthanum, <sup>45</sup>Ca<sup>2+</sup> uptake showed the same shear dependence in both ATP-rich and depleted cells as found for ATP-depleted cells in the absence of La3+. These results suggest that shear increases the Ca2+ permeability of the erythrocyte membrane through an effect on a La3+-insensitive Ca2+ channel.

While the net accumulation of 45Ca2+ into ATP-rich cells was only weakly shear dependent, Ca2+-dependent ATPase activity in these cells increased strongly with increasing shear rate over the same range as that used in the Ca<sup>2+</sup> uptake experiments (Fig. 3). The experiments were performed in ATP-rich cells treated with 5 mM iodoacetamide to limit glycolysis and the reincorporation of liberated  $P_i$  into  $ATP^{16}$ .  $(Na^+ + K^+)ATP$  and Mg<sup>2+</sup>-ATPase activities were at most only slightly affected (Fig. 3). The Na<sup>+</sup> permeability may thus be much less shear sensitive, or iodoacetamide may have rapidly brought the Na+ concentration in the cells to values saturating the Na<sup>+</sup> pump.

Circulating erythrocytes are subjected to periodic fluctuations in shear stress, conditions being most extreme in the microcirculatory beds. These stresses induce continuous dramatic deformations of the cell membranes. The present results obtained with the physiological shear rate range<sup>6</sup> of 50-

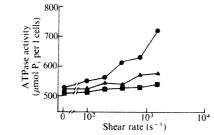

Fig. 3 Effect of shear rate on ATP turnover in ATP-rich human erythrocytes. ATPase activities were measured before and after shearing ATP-rich erythrocytes in the medium used in the <sup>45</sup>Ca<sup>2+</sup> uptake experiments in Fig. 1, but which also contained 5 mM iodoacetamide. The contribution of  $(Ca^{2+}+Mg^{2+})ATPase$  ( ) was measured in the presence of 0.1 mM ouabain;  $Mg^{2+}-ATPase$  ( ) was measured in the absence of  $CaCl_2$  and the presence of 1 mM EGTA and 0.1 mM ouabain;  $(Na^++K^+)ATPase$  ( ) was measured in the absence of  $CaCl_2$ .  $(Ca^{2+}+Mg^{2+})ATPase$  activity was defeate at the arther interest of  $CaCl_2$ . defined as the ouabain-insensitive activity determined in the presence of CaCl<sub>2</sub> minus the ATPase activity determined in the presence of 1 mM EGTA and no Ca<sup>2+</sup>. Samples (200 µl) of erythrocyte suspensions were placed in 1.5-ml centrifuge tubes with 200 µl ice-cold 10% perchloric acid and centrifuged for 1 min in an Eppendorf 5412 centrifuge. Inorganic phosphate was determined in each 200 µl of the supernatant by the method of Fiske and Subba Row22. Results are from a single experiment from volunteer 1.

5,000 s<sup>-1</sup> indicate that, coincident with such deformation, large increases in Ca2+ permeability occur. Hence, the level of internal Ca2+ in erythrocytes could show large transient increases in those parts of the circulation where shear stress is highest. Increased intracellular Ca2+ activity has been shown to increase the suspension viscosity of red cells without significantly affecting cell volume or unstressed shape 17. Ca2+-stimulated dephosphorylation of membrane substrates has also been correlated with the shape and shear resistance of erythrocyte membrane preparations<sup>18</sup>. The relationship between Ca<sup>2+</sup> permeability, Ca2+-dependent ATPase and pump activity, and intracellular biochemical events which are sensitive to Ca2+ levels may therefore be much more dynamic in the circulation than had previously been thought. Viewed in this light, even the twofold deficiencies in Ca<sup>2+</sup> pump activity seen in red cells from cyctic fibrosis patients<sup>19</sup> or in sickle cells<sup>20,21</sup> could acquire greater significance than has hitherto been afforded them.

## Alisphenoid equivalents in placentals, marsupials, monotremes and fossils

#### R. Presley

Department of Anatomy, University College, Cardiff, Box 78, Cardiff CF1 1XL, UK

The interpretation of the wall of the brain case between orbit and ear has important implications for mammalian phylogeny. The fossil mammalian groups morganucodonts, triconodonts and multituberculates possess a reduced alisphenoid and a large anterior process of the petrosal. In this they resemble monotremes. By contrast 'therians' (marsupials, placentals and their putative ancestors) have a large alisphenoid and no anterior process. Palaeontologists reject forms with a large anterior process from a position close to the ancestry of therians, though uncertain of the timing of the divergence1,2. The development of the brain case of monotremes is crucial here. The view that their anterior process is a laminar outgrowth of the petrosal3 has been widely accepted. Recent work has shown that this is not true in echidnas<sup>4,5</sup> and here I confirm the suggestion<sup>6</sup> that it is not true in platypus. The ossification pattern of living mammals indicates the possibility of close affinity between 'therian' and 'nontherian' mammals.

The area of interest develops in the lateral wall of the cavum epiptericum, the cartilaginous ala temporalis in front and the cartilaginous otic capsule (future petrosal) behind. In all mammals a fibrous spheno-obturator membrane<sup>7</sup> lies between these, extending up to the edge of the chondrocranium lateral to the ophthalmic nerve. Terminology of this area has varied. Here I use 'processus ascendens' for the part of the ala between ophthalmic and maxillary nerves; 'lamina ascendens' for the part of the ala between maxillary and mandibular nerves. The English word 'process' signifies an adult osteological feature and 'lamina' is confined to development. I propose here that the more recent term 'lamina obturans'4-6 used for membrane bone developing in the spheno-obturator membrane of monotremes may usefully be extended to the very similar field of membrane bone here in therians. This membrane bone is very variable in its development and fate in Recent mammals and may well be the key to the evolution of this region in advanced therapsids.

I present here two stages from a developmental series of serially-sectioned platypus nestlings. The younger specimen has a small lamina obturans: a single sheet of membrane bone entirely separate from the otic capsule and ala temporalis (Fig. 1a). The older specimen, used by Watson<sup>3</sup>, was the only one available to him having a lamina suitable for histological study. He described it as a forward outgrowth of the petrosal, founding the prevalent morphological view. In this specimen the area of synostosis between the lamina obturans and endochondral bone in the otic capsule is very small (Fig. 1b); in the younger specimen the otic capsule shows no sign of endochondral ossification here. It is clear from these and other specimens that the platypus lamina obturans is an independent centre of intramembranous ossification within the spheno-obturator

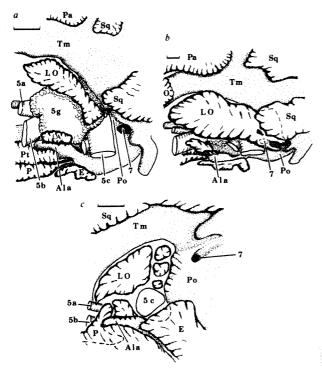

Fig. 1 Temporal regions of a, Ornithorhynchus anatinus, 168 mm snout-tail (ST), lateral aspect; b, O. anatinus, 250 mm ST, lateral aspect; c, Tachyglossus aculeatus, 174 mm ST, ventral aspect. Scale bar, 1 mm. Cartilage is shown stippled, bone with edges scalloped. a Shows a large lamina obturans (LO) barely touching the petrosal (Po). b Has the lamina synostosed with the petrosal in the area overlapped by the squamosal (Sq). c Is drawn from the oldest available specimen: the temporal wing of the palatine and lamina ascendens' (LA) were ossified but the position of other ossifications in the membrane and petrosal are based on refs 4, 5. Ala, ala temporalis; E, ectopterygoid; P, palatine; Pt, pterygoid; Tm, taenia marginalis. 5a,b,c,g, Ophthalmic, maxillary and mandibular nerves and trigeminal ganglion, respectively. 7, Foramen of facial nerve.

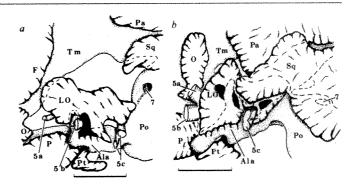

Fig. 2 Temporal regions of a, Didelphis virginiana, 24 mm crown-rump (CR), lateral aspect; b, Erinaceus europaeus, 14.5 mm head length (HL), lateral aspect. Same scale as in Fig. 1. There is an extensive area of membrane bone with similarity to the monotreme lamina obturans in each, but there is little endochondral ossification in the ala temporalis. The dark areas in each lamina indicate schematically where, in younger specimens (14 mm CR opossum, 13 mm HL hedgehog), the earliest ossification in adjacent cartilage. The great variability of the ala temporalis in mammals is illustrated by the presence in the opossum of a cartilaginous processus ascendens between 5a and 5b, while the hedgehog lacks this but has a lamina ascendens between 5b and 5c.

membrane, analogous to the multiple centres described in echidnas  $^5$  (Fig. 1c). Watson  $^3$  lacked younger platypus having this bone and overlooked the possibility of its independent origin.

The structure of this region in monotremes may be summarized as follows: in platypus the small ala temporalis ossifies quite early, with a small perichondrial extension into the spheno-obturator membrane ('lamina ascendens'5). A single lamina obturans appears which fuses first with the petrosal and later with orbitosphenoid, squamosal, palatine and 'lamina ascendens'<sup>5</sup>. Other workers<sup>4,5</sup> have shown that the echidna lamina obturans appears late as several centres; my specimens show here early signs of ossification consistent with these reports, but lack later juvenile stages. The ala temporalis is smaller than that of the platypus but ossifies early and produces a larger perichondrial extension ('lamina ascendens'<sup>5</sup>) into the spheno-obturator membrane, as do the palatine and the anterior margin of the petrosal. In echidnas, closure of the suture between lamina obturans and petrosal may be later than with adjacent elements<sup>5</sup>. It is still visible, though unlabelled, in Watson's figures of echidna (G. T. MacIntyre, personal communication).

All recent therians have a spheno-obturator membrane, in which membrane bone appears earlier than in monotremes, often before endochondral ossification in the ala temporalis, unlike the monotreme 'lamina ascendens'. It appears close to the ala and extends back to suture with the squamosal and tegmen tympani. It is very variable in shape and number of centres. The opossum (Fig. 2a) has a pattern similar to the platypus; the hedgehog (Fig. 2b) has three centres. This membrane bone is histologically and anatomically similar to the lamina obturans of monotremes and forms most of the blade of the alisphenoid of therians, the ala temporalis forming a usually smaller portion from root to nerve exits.

smaller portion from root to nerve exits.

Previous analysis<sup>8-10</sup> holds that the therian alisphenoid, while histologically a complex of membrane and cartilage bone, should be treated morphologically as a derivative of the epipterygoid of primitive tetrapods, the membrane bone being merely a large perichondrial extension of the processus ascendens of the epipterygoid which has been modified and reduced to the ala temporalis. This view is simple and very effective, but note that it was founded before information on the true development of monotremes was available, before excellent

fossil cranial material of Mesozoic mammals was known and at a time when the alisphenoid-epipterygoid theory of synapsid evolution was still controversial<sup>3,11,12</sup>. We now need to take account of the extent of this membrane bone, present in all mammals in a large part of the region, and to allow for its very variable pattern, in taxonomic analysis.

There seems to be no fundamental difference between therians and monotremes in the early development of this bone. Differences arise only when it fuses with its neighbours. It may well have been that the precursors of mammals had membrane bone in this region: cynodonts may have had an anterior part contributing to the broad blade of the epipterygoid and a posterior forming the smaller anterior process of the petrosal. In other groups the proportions may have varied: in triconodonts the anterior process is larger and the epipterygoid blade smaller, while in multituberculates the membrane-bone area may have contributed extensively to the petrosal to the exclusion of the diminutive alisphenoid (epipterygoid). In view of the variable pattern found in living forms and the difficulties of establishing detailed osteological homologies in fossils, it must surely be dangerous to erect two groups, however informally, based on

the adult pattern of this region. Development shows that there is no 'monotone pattern' and therefore fossils may not be categorized as sharing it.

Excellent skull material of morganucodonts<sup>1</sup>, triconodonts<sup>2</sup> and multituberculates 13,14 is now being studied. It must be appreciated that the blade of the alisphenoid and the anterior process of the petrosal are developmentally very similar and may be morphologically almost equivalent. If Mesozoic, like Recent, mammals formed membrane bone in the area of the lamina obturans, it follows that any form in the fossil record with an expanded epipterygoid, an anterior process of the petrosal, or both, could, by a simple change in the affinity of synostosis during development15, come to possess therian anatomy. Therefore the recognition of the precursor form of therians must rest on other features. The structure of the wall of the cavum epiptericum itself in morganucodonts, triconodonts, multituberculates, cynodonts or even monotremes does not exclude close affinity to therians.

I thank Dr H. L. H. H. Green and Professor R. J. Harrison for the loan of monotreme material. This work was supported by SRC grant GR A 68004.

#### Corrigenda

A correction to the letter '210Pb in surface air at Enewetak and the Asian dust flux to the Pacific' by Karl K. Turekian & J. Kirk Cochran, Nature 292, 522-524.

We have just discovered that the filters sent to us for <sup>210</sup>Pb assay and reported in our recent paper were one-quarter aliquots of the total filter and that the values for volumes transmitted to us subsequently were for the whole samples. This means that Table 1 in our paper must be revised to increase the <sup>210</sup>Pb concentration in Enewetak air by a factor of 4: the correct version is shown below.

Table 1 210Pb and 210Po in air filter samples from Enewetak, April-August 1979

	<sup>216</sup> Pb	<sup>210</sup> Po/ <sup>210</sup> Pb
Date of sampling	$(d.p.m. 10^{-3} m^{-3})$	activity ratio
18 April	$15.3 \pm 2.1$	ener.
26 April	$12.1 \pm 1.0$	$-0.02 \pm 0.08$
3 May	$10.4 \pm 0.76$	$-0.02 \pm 0.03$
10 May	$12.2 \pm 1.0$	$-0.02 \pm 0.03$
15 May	$7.96 \pm 0.72$	$-0.08 \pm 0.03$
20 June	$5.96 \pm 0.20$	$0.14 \pm 0.11$
8 July	$8.00 \pm 0.32$	$0.02 \pm 0.28$
16 July	$3.17 \pm 0.14$	$-0.26 \pm 0.04$
26 July	$3.11 \pm 0.076$	$0.17 \pm 0.07$
4 August	$4.04 \pm 0.16$	$0.05 \pm 0.07$
ver blanks (filter carrie	ed up the sampling tower in ex	(posed conditions)
10 May	$0.424 \pm 0.108$	$-0.09 \pm 0.10$
26 Iuly	$0.180 \pm 0.032$	$-0.05 \pm 0.18$

Sampling date represents the date corresponding to the midpoint of the collec-

This correction changes several relations that we discussed.

- (1) Both the ordinate values for Fig. 1 and the abscissa values in Fig. 2 should be increased by a factor of 4.
- (2) The corrected Enewetak filter results (present Table 1) compare more favourably with previous observations made at Hawaii<sup>2</sup>. Between 15 May and 20 June 1979 at Enewetak, the concentration of <sup>210</sup>Pb was 6-8 d.p.m.  $10^{-3}$  m<sup>-3</sup> and for a similar period (30 May-22 June 1971) at Hawaii the values below the tradegraph. Hawaii, the values below the trade wind inversion were 3.4-19.4 d.p.m.  $10^{-3}$  m<sup>-3</sup> with a mean of 9.3 d.p.m.  $10^{-3}$  m<sup>-3</sup>.
- (3) The regression equation for the calculation of the mean annual concentration of <sup>210</sup>Pb in air becomes

C [d.p.m. <sup>210</sup>Pb 10<sup>-3</sup> m<sup>-3</sup>] = 18.8-85.6×F [d.p.m. <sup>210</sup>Pb cm<sup>-2</sup> yr<sup>-1</sup>]

For a mean flux of  $^{210}\text{Pb}$  of  $0.15\,\text{d.p.m.}$  cm  $^{-2}\,\text{yr}^{-1}$  this yields a mean annual concentration in air of 6 d.p.m.  $^{210}\text{Pb}\,10^{-3}\,\text{m}^{-3}$ .

- (4) The slope (S) of the regression equation correlating  $F_{AI}$  with  $F_{Pb}$  becomes 9.5 µg Al per d.p.m. <sup>210</sup>Pb.  $F_{AI}$  then becomes 0.63 µg Al cm<sup>-2</sup> yr<sup>-1</sup> corresponding to a dust flux (assuming 6.5% Al) of 9.6±5 µg cm<sup>-2</sup> yr<sup>-1</sup>, a closer value to that reported by Duce et al.<sup>3</sup>.
- (5) In Table 2 of our paper the increase by a factor of 4 of the mean Pb concentrations reported there decreases the 'total deposition velocities' by a factor of 4. Thus 'dry' season total deposition velocity becomes  $0.25~{\rm cm~s}^{-1}$  and the 'wet' season becomes  $1.0~{\rm cm~s}^{-1}$ . These values are now lower than our estimated deposition velocities for Hawaii  $(\sim 3 \text{ cm s}^{-1})$  and Bermuda  $(\sim 4 \text{ cm s}^{-1})$ .
- (6) The dust flux calculated for Hawaii using the parameters of the Enewetak <sup>210</sup>Pb-Al regression equation now becomes 93 μg cm<sup>-2</sup> yr<sup>-1</sup>. This is easily in the range of accumulation rates of clay on the deep ocean floor. The conclusion regarding the dominance of the Asian dust flux to the sedimentation in the Pacific remains intact as does the suggestion that post depositional homogenization has occurred.

   Moore, H. E., Poet, S. E. & Martell, E. A. J. geophys. Res. 79, 5019-5024 (1974).
   Duce, R. A. et al. Science 209, 1522-1524 (1980).

In the letter 'Is the similarity of monozygotic twins due to genetic factors alone' by K. Gärtner and E. Baunack, Nature 292, 646-647, in Table 1 mean  $\pm$ s.d. of the MZ should be  $26.41 \pm 2.58$  instead of  $26.2 \pm 2.66$ , and in Tables 1 and 2 the  $s_b^2$  values of 51- and 61-day old DZ should be -1.18 and -2.49 instead of the printed positive values. In Table 2, the calculated F values of the  $s_b^2$  of MZ and DZ are statistically insensitive; therefore the F and P values of  $s_b^2$  should be disregarded.

The title of the letter by Doyle R. Watts and Andrew M. Bramall in Nature 293, 638-641 should read 'Palaeomagnetic evidence for a displaced terrain in Western Antarctica'.

In the letter 'SB: a new HLA-linked human histocompatibility gene defined using HLA-mutant cell lines', Nature 293, 747-749, the present address of Fritz H. Bach should read 'Immunobiology Research Center, University of Minnesota, Minneapolis, Minnesota 55455, USA

In the review article 'A new era in mammalian gene mapping: somatic cell genetics and recombinant DNA methodologies' by F. H. Ruddle, Nature 294, 115-120, on p. 119 ' $\alpha$ -globin' should read ' $\beta$ -globin' throughout. In Table 1, the chromosome positions for the mouse  $\alpha$ -globin pseudogenes are sited incorrectly: pseudogene  $\psi$ 3 maps to chromosome 15 and pseudogene  $\psi 4$  to 17.

#### Presence and physiological role of presynaptic inhibitory α<sub>2</sub>-adrenoreceptors in guinea pig atria

IT was concluded by Angus and Korner<sup>1</sup> "presynaptic  $\alpha$ -adrenoreceptor that modulation by synaptically released noradrenaline plays no part in cardiac sympathetic transmission".

Evaluation of their results and experimental methodology suggests that this criticism may be premature because there are important methodological differences between this study and several others which showed evidence for presynaptic α-adrenoreceptor modulation of cardiac neurotransmission. As the consensus of opinion supports a physiological role for presynaptic  $\alpha$ -adrenoreceptors in the heart, it is useful to identify and examine these experimental differences in more detail.

(1) The study was carried out with guinea pig right atria in Krebs' solution which contains 1.2 mM Mg<sup>2+</sup>. In these experimental conditions the resting rate<sup>1</sup> is only 110 beats per min while in most articles dealing with spontaneously beating guinea pig atria and using Locke's solution, which does not contain Mg<sup>2+</sup>, the resting rate<sup>2-5</sup> is between 200 and 230 beats per min.

Angus and Korner state that "phentolamine 0.3-10 µM had no significant effect on the resting atrial rate or the dose-response curve to noradrenaline"1. The fact that their resting rate was already very low may explain their findings.

However, the authors1, without admitting their different resting atrial rate, presented these results as conflicting with findings by Langer et al.6 of a negative chronotropic effect and attenuated chronotropic responses to exogenous noradrenaline in the presence of 31 µM phentolamine. However, the results of Langer et al.6 were obtained with Locke's solution in conditions in which the resting atrial rate<sup>6</sup> was 210 beats per min. When repeating their experiments with Locke's solution Angus and Korner found that, as reported previously6, even 10 µM phentolamine produced a significant negative chronotropic effect in guinea pig atria (J. A. Angus, personal communication). Angus and Korner did not determine phentolamine  $31 \mu M$ whether antagonized responses of atria to exogenous noradrenaline as reported by Langer et al.6.

(2) Instead of accelerans nerve stimulation<sup>6</sup> the experiment by Angus and Korner used field stimulation<sup>1</sup>; clearly, the latter is a less physiological stimulus than nerve stimulation, and this difference in methodology may be one of the reasons

for their negative results. In support of the results of Langer et al.6 it was recently reported that both phentolamine and produce a significant yohimbine enhancement of the inotropic responses to sympathetic stimulation in guinea pig left atria7.

(3) Potentiation of the chronotropic responses to accelerans nerve stimulation at 0.5 Hz was reported in the presence of 0.1 µM phentolamine6. Using one or four pulses of field stimulation applied during the refractory period, exposure to 10 µM phentolamine failed to potentiate the chronotropic responses to field stimulation1. Recent experiments in which field stimulation was applied in guinea pig atria using four pulses at 2 Hz showed that exposure to 3 µM phentolamine did not significantly affect the overflow of <sup>3</sup>Hnoradrenaline8, thus confirming the observation of Angus and Korner<sup>1</sup>. However, when field stimulation was applied at 2 Hz using a total of 16 pulses, to 3 µM phentolamine exposure enhanced the overflow of the labelled transmitter as well as the peak chronostimulation8. responses to Obviously, the negative feedback regulation of noradrenaline release mediated by presynaptic  $\alpha_2$ -adrenoreceptors depends on the frequency and duration of neuronal activity. Failure to observe potentiation of the positive chronotropic responses to field stimulation in the report by Angus and Korner<sup>1</sup> is clearly related to the fact that they used too short a period of stimulation. These results8 confirm the findings of Langer et al.6 obtained with accelerans nerve stimulation.

It is premature to reach definitive conclusions, as did Angus and Korner, about the absence of feedback modulation of noradrenaline release based on negative results originating from inadequate experimental conditions which are restricted to very brief periods of stimulation. If these authors had explored a wide variety of frequencies of stimulation using different durations of the period of stimulation, their conclusions would have been quite the opposite, as clearly demonstrated by Story et al.8.

(4) Although the presence of presynaptic inhibitory  $\alpha_2$ -adrenoreceptors in guinea pig atria is questioned by Angus have and Korner<sup>1</sup>, thev shown subsequently that clonidine, an  $\alpha_2$ adrenoreceptor agonist, decreases the responses to field stimulation in this tissue9. In addition, clonidine reduces the inotropic response to sympathetic nerve stimulation in guinea pig left atria and this effect is antagonized by 5 µM phentolamine or 0.1 µM yohimbine (ref. 7). These results clearly support the view that presynaptic inhibitory  $\alpha_2$ -adrenoreceptors are present in noradrenergic nerve endings of the peripheral nervous system 10-12. These release-modulating presynaptic  $\alpha_2$ -adrenoreceptors are definitely of pharmacological relevance in both in vitro and in vivo conditions 13,14 The possible physiological role of presy- $\alpha_2$ -adrenoreceptors in naptic noradrenergic neurotransmission is supported by the findings that  $\alpha_2$ adrenoreceptor blocking agents enhance both the electrically evoked release of noradrenaline and the end-organ responses to sympathetic nerve stimulation 10-12 provided suitable experimental conditions are used.

ANGUS AND KORNER REPLY-In our paper1 we tried to establish whether or not neurally released noradrenaline could activate an auto-inhibitory feedback on the sympathetic nerve terminals of the guinea pig right atrium and concluded that it did not. There were differences between our methodology and those of Langer and co-workers and we are grateful for the opportunity of discussing these.

(1) Bath solution. We used a standard bicarbonate-buffered solution for heart muscle<sup>2-4</sup> of pH  $7.58 \pm 0.01$  (n = 5) bubbled with 95% O<sub>2</sub>, 5% CO<sub>2</sub>, compared with Langer and co-authors<sup>5-7</sup> who routinely use Mg<sup>2+</sup>-free Locke's solution bubbled with 100% O<sub>2</sub>. We found that this Locke's solution has a pH of 8.19 ± 0.06 (n=4), a similar finding to Trendelenburg8 and well outside the normal physiological range. The higher resting rate in Locke's solution of 180-210 beats per min compared with our rate of 110-150 beats per min are accounted for by the well known effect of pH on resting atrial rate<sup>9,10</sup> rather than the lack of Mg<sup>2+</sup> which, parenthetically, is present in guinea pig

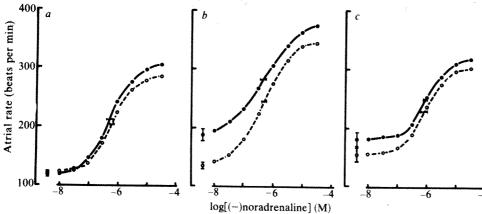

Fig. 1 Effect of 10 µM phentolamine (30 min contact) on resting atrial rate and on chronotropic responses to exogenous (-)noradrenaline in isolated guinea pig right atria in three different bath condi tions. a, Krebs' solution, pH 7.58, temperature 37 °C (n = 4): control, first curve; phentolamine, fifth curve (data from ref. 1). b, Krebs' solution, pH 7.58, temperature 38.4 °C (n = 6); control, first curve; phentolamine, second curve. c, Locke's solution, pH 8.19, temperature 37 °C (n = 4); control, first curve; phentolamine, second curve. Solid symbols = control; open symbols = phentolamine. Means ± s.e.m. at the left of each graph are the resting atrial rates before the start of the noradrenaline curve.

plasma  $(0.86 \pm 0.08 \text{ mM}, n = 4)$ . As pointed out by Blinks and Koch-Weser<sup>11</sup>, "the solution that produces the most vigorous contractions is not necessarily the most physiological one... The most physiological solution is one that most closely the normal extracellular resembles fluid . . .

(2) Phentolamine. We agree that the lower resting rates in our preparations1 may have masked the negative chronotropic effect of high phentolamine concentrations (10 µM). By raising the temperature of the bath from 37 °C to 38.4 °C (body temperature in conscious guinea pigs) the resting rates were now  $186 \pm 29$  (n = 6), significantly higher than at 37 °C. In these conditions, as with Locke's solution at 37 °C, 10 µM phentolamine significantly lowered the resting rate (Fig. 1). However, the sensitivity (threshold and ED<sub>50</sub> value) and range (change in rate) of the exogenous noradrenaline concentration-response curves were not significantly altered by phentolamine (negative log molar ED<sub>50</sub> values: Krebs', 38.4 °C (n = 6), control = 6.33 ± 0.11, phentolamine 6.31 ± 0.09; Locke's 37 °C (n = 4), control = 6.03 ± 0.03, phentolamine  $6.08 \pm 0.09$ ). Therefore, we cannot conclude that 10 µM phentolamine antagonizes the atrial responses to noradrenaline, a suggestion used by Langer and co-authors to explain why phentolamine (3.1 µM) failed to potentiate atrial responses to nerve stimulation on two occasions<sup>5,6</sup> despite a large but variable increase in 3Hnoradrenaline release. It is interesting that Langer<sup>5</sup> has observed an increase in the rate response after 0.31 µM phentolamine with nerve stimulation at 0.5 Hz for 10 s, but that in the same study<sup>5</sup> the supporting evidence of increased noradrenaline release was made at nerve stimulation of 4 Hz for 60 s, a stimulus that produces near maximum rate response<sup>6</sup>. Higher concentrations of phentolamine (31 µM) appeared depress the resting atrial rate and to shift the exogenous noradrenaline concentration-response curve to the right<sup>5</sup>. The relevance of these data is not clear, as Langer and colleagues<sup>5</sup> presented no results on 3H-noradrenaline release or rate response at this concentration.

(3) Accelerans nerve stimulation. The advantage of field stimulation is that all nerve varicosities are depolarized synchronously by each field pulse<sup>12</sup>. With nerve stimulation there is some evidence 13,14 that action potentials may not always invade all the terminal varicosities. Stjärne<sup>15</sup> points out that drugs may potentiate noradrenaline release by recruitment of varicosities. Therefore, to test the hypothesis of auto-inhibitory feedback, it is logical to eliminate varicosity recruitment by using field stimulation, a technique used by others in examining noradrenaline release atria4.

Therefore, we believe that the methodological points raised by Langer do not invalidate our conclusion that physiologically released noradrenaline does not activate auto-inhibitory receptors in the conditions of our assay. If the widely championed view that presynaptic  $\alpha$ -adrenoreceptors are important in sympathetic transmission in physiological conditions, we assert that phentolamine should have raised responses after four pulses. After all, a "pulse-to-pulse modulation of noradrenaline release" was proposed by Rand and colleagues 16 and has often been quoted by Langer<sup>17</sup>.

Recently, as Langer points out, Story and colleagues have confirmed our results that the tachycardia resulting from four field pulses that give up to 50% maximum response is unaffected by phentolamine. However, an increase in response was observed in the presence of phentolamine after 16 field pulses, which cause near maximal tissue response. In our experiments, field pulses were delivered only in the atrial refractory period to avoid arrhythmia, in marked contrast to the random delivery in experiments by Story et al. 18. They have now described conditions in which the feedback loop seems to operate even for four field pulses provided the frequency is ≤1 Hz. If the conditions for the operation of the feedback loop are so critical, it is difficult to imagine how a nerve varicosity can be involved in feedback control in normal conditions when not every impulse from nerve trunk stimulation invades each varicosity.

We too have found that clonidine inhibits the sympathetically mediated

tachycardia and that this action is antagonized by low concentrations of phentolamine  $(0.1 \mu M)^{19}$ . Therefore, we agree that there is an important pharmacological target on cardiac sympathetic nerve terminals which is probably related to a presynaptic  $\alpha$ -adrenoreceptor and where some imidazolines show high affinity.

Finally, our paper has, of course, not examined all conditions of stimulation because we attempted to examine the role of presynaptic  $\alpha$ -adrenoreceptors in conditions producing a moderate tissue response. Clearly, our paper and that of Story et al. highlight the need for caution in assuming a general operation of autoinhibitory feedback in cardiac sympathetic transmission.

# Satellite-sensed turbulent ocean structure

RECENTLY Gower et al.1 have reported results concerning interesting concentration of phytoplankton measured by the Landsat multispectral scanner on 19 June 1976 in a region south of Iceland. The observed concentration fluctuation spectra is found to follow approximately a  $k^{-2.92}$  law, close to the  $k^{-3}$  law proposed by Charney<sup>2</sup> for the energy spectrum of quasi-geostrophic flows. They conclude that this result is consistent with the hypothesis that phytoplankton behaves like a passive scalar convected by ocean currents.

The quasi-geostrophic theory of Charney<sup>2</sup> predicts  $k^{-3}$  laws for both horizontal kinetic energy and temperature variance, however, temperature is not a passive scalar, but the vertical derivative of the horizontal stream function. It is the constraints of total (kinetic plus available potential) energy conservation potential enstrophy conservation

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\psi_x^2+\psi_y^2+\psi_z^2\rangle=0$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\psi_{xx}^2+\psi_{yy}^2+\psi_{zz}^2\rangle=0$$

together with the assumption of statistical isotropy, which yields for any of the derivatives  $\psi_x$ ,  $\psi_y$ ,  $\psi_z$  a power spectrum following a  $k^{-3}$  law in the potential enstrophy cascading range.

Now, if we consider a passive scalar convected by the quasi-geostrophic motion, as we may expect phytoplankton is, the situation must be quite different. For simplicity we neglect baroclinic effects: for pure two-dimensional turbulence, it can be shown<sup>3</sup> using either phenomenological arguments or statistical closures, that the spectrum of a passive scalar is proportional to the spectrum of the quantity which cascades. Therefore in the enstrophy cascading inertial range, the spectrum of a passive scalar should follow a  $k^{-1}$  law, like the enstrophy (and not the energy) spectrum. There seems to be no reason why this result could not be extended to quasi-geostrophic turbulence which follows a similar phenomenology. A  $k^{-3}$  energy spectrum for the ocean currents would then imply a  $k^{-1}$  law for the passive scalar; conversely, a  $k^{-3}$  spectrum for the passive scalar variance of the type reported by Gower et al.1 would imply a much steeper slope  $(k^{-5})$  for the current kinetic energy.

Such steep slopes have been found in fact in numerical simulations of forced two-dimensional turbulence4; the consequent discrepancy with the Kolmo-

gorov-Kraichnan-Leith theory<sup>5</sup> which predicts a  $k^{-3}$  law is still an open question. For instance, the presence of intermittency effects would yield a steepening of the energy spectrum4; but still, neither kinetic energy spectra nor temperature variance spectra steeper than  $k^{-3}$  have yet been observed experimentally.

The quasi-geostrophic theory of Charney2 neglects the influence of upper and lower boundaries; it is therefore likely to be valid in the deep ocean rather than near the surface. Near the surface the dynamics is likely to involve the occurrence of frontal systems, and one should refer to the quasi-geostrophic theory of Blumen<sup>6</sup> rather than to that of Charney2. In Blumen's<sup>6</sup> theory potential vorticity is assumed to vanish

$$\psi_{xx} + \psi_{yy} + \psi_{zz} \equiv 0$$

inside the fluid, and the two invariants are the total energy of the fluid, and the available potential energy at the surface, which both reduce to integrals taken over the surface only:

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\psi_z^2\rangle=0$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\psi_{zz}^2\rangle=0$$

The quantity which cascades to smaller scales is the available potential energy at the surface, which therefore exhibits a  $k^{-5/3}$  law characteristic of frontal systems. If we follow this theory, which looks more appropriate than the first one in the case of surface dynamics, we end up with a  $k^{-5/3}$ law of the passive scalar variance. This is again quite far from what has been observed for phytoplankton, although again the presence of intermittency could yield a steeper slope.

It seems, therefore, difficult to infer anything conclusive from the measurements reported by Gower et al.1 concerning a possible behaviour of phytoplankton as a passive scalar. Also, some caution

# **Matters Arising**

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

should be observed regarding regression estimates for spectral slopes. The concept of an inertial range is only asymptotically valid, and the data used by Gower et al. may be close to the internal radius of deformation to yield any sensible approximation to the actual behaviour of the inertial range. Apparently a regression calculated on the range 1-10 km would vield much lower values of the slope.

A secondary point concerns the assumptions in Gower et al.1 that radiance upwelling is a linear function of phytoplankton concentration. The only assumption needed to investigate the passive scalar character of phytoplankton is that radiance upwelling is a function of phytoplankton concentration because any function of a convected quantity is a convected quantity, exhibiting therefore the same spectral behaviour.

GOWER ET AL. REPLY-In our recent paper<sup>1</sup>, the -2.92 slope found for the spectrum of near-surface phytoplankton variance is not consistent with theories of a passive scalar in a quasi-geostrophic turbulent fluid. The reasoning is based on a subsequent paper by Lesieur et al.2

However, we do not feel that a further search for physical explanations for our spectrum is warranted: phytoplankton are not always a conserved passive scalar. Rather, as microscopic plants in the sea, they grow, at times at rates capable of doubling their weight each day; and they die or are eaten, often at rates comparable with their growth rates. These time scales are short compared with typical time scales for quasi-geostrophic eddies (10 days). Even in the absence of turbulent motion, biological processes can result in similar negative power law spectra<sup>3</sup>. Still it is feasible that areas of abundant phytoplankton may correlate with fluctuations of a dynamic variable, such as upwards

velocity or temperature, in which case the spectra of temperature and phytoplankton variance might be similar.

The point that all convected quantities in a quasi-geostrophic turbulent field will have the same variance spectrum even if they are related in a non-linear manner, if it is correct, increases our confidence that our published spectra are an accurate representation of the near surface phytoplankton variability. We can still envision that constraints of calculating a spectrum, such as the apparent diffusion caused by the finite size of picture elements and the necessity to average over picture elements, might cause convected quantities related in a non-linear manner to have different calculated spectra.

# Problem of light piping in immunofluorescence studies

In providing evidence from indirect immunofluorescence for the presence of myosin in the stereocilia of cochlear hair cells, Macartney et al.1 present a figure in which fluorescent light, in the pattern of stereocilia, emanates from the apical surface of hair cells. As the arrangement of the actin filaments which form the core of the stereocilium places structural constraints on the location of significant amounts of other proteins, if myosin is present in the stereocilia, it would have to form either the inter-filament crossbridge or be located in the space between the core and the membrane, both of which seem unlikely. Therefore the results of Macartney et al. were puzzling. This led me to consider the possibility that they were an artefact of light piping. I have subsequently learned that Macartney et al. (personal communication) have taken transverse sections of the organ of Corti. showing fluorescence along the lengths of the stereocilia, thus making light piping a less likely explanation of their results. Nevertheless, for the sake of future studies on the localization of immunofluorescence in hair cells we now explain the problem of light piping so that precautions can be taken to exclude it as a source of spurious results.

Light piping was first observed with respect to hair cells in the last century, and

has been described more recently by Kohlloffel<sup>3</sup>. Hair cells, because they have a higher refractive index than the surrounding extracellular medium, behave as optical waveguides (the 'fibre optic effect); light entering these cells obliquely Kohlloffel's treatment of this phenomenon<sup>3</sup> was restricted to the optical phenomenon<sup>3</sup> was restricted to the optical properties of the hair-cell body (which is roughly cylindrical in shape), but other observations suggest that the stereocilia, emerging from the apical surface of the cell, can enhance this effect.

It would be convenient if one could make a detailed description of the exact optical properties of the stereocilia, but this is almost impossible, due to the necessity of solving Maxwell's equations for discrete electromagnetic modes within a complicated geometry (each stereocilium has a diameter of the order of the wavelength of light). Nevertheless, observations of the stereocilium structure<sup>4</sup> enable one to make a rough estimate of the parameters involved in this fibre optic effect. The density of actin alone in the stereocilia is 0.4 g cm<sup>-3</sup>. If we include the contribution of a cross-bridging protein, a reasonable estimate for the total protein density might be  $0.55\,\mathrm{g\,cm^{-3}}$  in the stereocilium core. Using a specific refractive index increment of 0.18 for proteins, one finds a refractive index within the sterocilium of 1.43, as opposed to 1.33 for the surrounding endolymph (assumed to be that of water). Thus, the numerical aperture (NA) for this waveguide, which is a measure of the angular acceptance of the fibre, would be  $\sim 0.5$ , a value quite similar to that which is obtained for the rod outer segments of the retina, a known biological fibre optic structure. The larger the NA, the greater the light-gathering properties of a fibre. This NA value might be compared with that of =0.3 given by Kohlloffel for the body of the hair cell. Although the fibre characteristic term, R, for the stereocilium is quite small (1-3, as opposed to 10-20 for the hair-cell body) and the number of propagating modes will therefore be small for an isolated stereocilium<sup>5</sup>, it is quite probable that collective behaviour of the approximately 100 closely spaced stereocilia on each hair cell will be in the rule. Thus, the stereocilia bundle would still be observed macroscopically to behave as a light pipe.

This effect might be observed in several different ways. One would be to illuminate the cell externally, as Kohllofel did, and look for localized brightness at the stereocilia tips. Alternatively, one might introduce a fluorophore which could freely diffuse within the cell. Light being selectively emitted from the stereocilia tips would then indicate the existence of the fibre optic effect described above. The latter approach already seems to have been tried for reasons other than verifying the existence of this effect. Goldstein

diffused fluorescein diacetate (FDA). which is non-fluorescent and non-polar (lipid soluble), through the membrane of hair cells. The FDA is hydrolysed to fluorescein by nonspecific esterases within the cells. Fluorescein, which is fluorescent, is also polar, so it will not freely diffuse out through an intact membrane. A cell with a completely non-permeable membrane would then show fluorescence increasing with time as more and more FDA diffused in. Permeable cells would lose fluorescence as the rate of fluorescein diffusing out exceeded the rate of FDA diffusing in. The object of Goldstein's study was to determine changes in the permeability of hair-cell membranes as a function of sound exposure and oxygen deprivation. However, he observed a particular anomaly described as "spots of fluorescence at the top of each cell... Because of the 'W' pattern of these dots, these presumably were the cilia of the hair cells". Because fluorescein does not bind to any known cellular structures, and because the light-piping effect was not considered, Goldstein assumed that the stereocilia are separated from the hair-cell cytoplasm by a unique membrane of their own. This postulated membrane would allow fluorescein to be retained within the stereocilia, causing the localized fluorescence. As no such membrane structure has ever been observed in detailed electron microscopic investigations, it is more probable that Goldstein's pictures are a good example of stereocilia light piping.

The importance of these points is underlined by the number of people using immunofluorescent localization of proteins in general within biological systems, and particularly those using this technique on hair cells. When one considers the striking resemblance of the photograph published by Macartney et al.1 to those taken by both Kohlloffel<sup>3</sup> (with external illumination) and Goldstein<sup>6</sup> (with diffuse internal illumination), it is obvious that one cannot distinguish between the different sources of the illumination in these photographs. All light seems to be emerging from either the apical surface of the cells or the stereocilia in all three cases.

1981. 59 figures. Approx. 700 pages. (Springer Series in Statistics) Cloth DM 108,—; approx. US\$50.30 ISBN 3-540-90558-8

Contents: Preliminaries. — Statistical Decision Techniques. — Statistical Methods in Medicine and Technology. — The Comparison of Independent Data Samples. — Further Test Procedures. — Measures of Association: Correlation and Regression. — The Analysis of k by 2 and by Two Way Tables. — Analysis of Variance Techniques. — Bibliography and General References. — Exercises. — Author Index. — Subject Index.

Applied Statistics is a sourcebook of statistical methods for scientists and engineers. The coverage of basic statistics, including a wide variety of techniques, tables, and computational aids, is notably thorough and complete. The book stands out from other elementary statistics books in its emphasis on medicine and the biological sciences, and by its comprehensive review of the literature on such aspects as statistical tests and experiment design.

# Research Monographs in Cell and Tissue Physiology

# Liposomes: From Physical Structure to Therapeutic Applications

# edited by C.G. Knight

This volume, the sixth in the well-established series, provides a comprehensive and up-to-date account of detailed reviews on both the physical and biological properties and applications of liposomes. Written by experts in this field of research the book describes the recent advances in both these areas, providing detailed descriptions of the current biophysical and biochemical studies on liposomes. For research workers and advanced students in the field of model membrane studies this book will be of great value.

### Contents:

# The order of life — towards a comparative biology

Ian R. Ball

WERNER Heisenberg once said that a revolution in science could be recognized by old terms acquiring new meanings and by an increase in philosophizing by its practicians. Systematic biology is clearly in the midst of revolution and this is nowhere more clearly indicated than in these two splendid books. Their effect may be long in the making, however, for the shadow of Darwin has indeed fallen colossus-like over systematic biology for over a century and our concepts of biological order in space and in time are suffused with his ideas.

For Darwin, geographical distribution was an indispensable key to nature and he established what has become the traditional approach to this subject. He believed all the leading facts of geographical distribution to be explicable in terms of single centres of creation with subsequent migrations, largely due to chance dispersal, further modification and and multiplication of new forms. In the hands of his followers such as Matthew, Simpson, Darlington and Mayr, biogeography thus became concerned with centres of origin, means and routes of dispersal, climate and the evolution of dominance, and the analysis of biotic components in terms of colonizer elements. Despite the considerable achievements of these authors, their derogation being one of the least attractive aspects of both of these books, their biogeography can now be seen to be incomplete for the Herculean, often polemical, labours of Léon Croizat to combat these ideas are becoming increasingly well known. Arguing that the distributions of a wide variety of organisms over the face of the Earth were not random, but orderly, Croizat stressed ad nauseam that dispersal was no explanation. Recognizing that Earth and life evolve together, he pointed the way towards a synthesis of the geological and biological sciences.

For Croizat the history of life involves periods of mobilism, when species movement occurs in the absence of barriers to such movement, and periods of immobilism, when speciation occurs as the result of the erection of barriers and the fragmentation of ranges. This combination of geological-climatological and allopatric speciation events embraces the concept of vicariance. Thus we have a vicariance biogeography in which successive divisions of a parental biota replace the multiple and successive arrivals or sequential migrations of individual species. Sympatric distributions of closely

Vicariance Biogeography: A Critique. Edited by G. Nelson and D.E. Rosen. Pp.593. ISBN 0-231-04808-4. (Columbia University Press: 1981.) \$45.40. related species are the primary evidence that dispersal has occurred.

Vicariance Biogeography contains the proceedings of a symposium held at the American Museum of Natural History in 1979, and on the evidence of the published version I am sorry that I missed it. Like most symposium volumes it is diverse, wide ranging and it contains articles covering the full spectrum from pro- to contravicariance biogeography and its relationship to systematics. Brundin gives an especially valuable outline of Croizat's "panbiogeography" but it would be unfair to single out special praise in a volume of uniformly high quality which deals with almost all aspects of biogeography vicariance, dispersal, speciation, plate tectonics, the testability of biogeographical theories and so on. An especially happy idea was that of allowing space for the discussions of each paper and then giving the author the right of reply, and frequently the more interesting points are made in these sections. The breadth and quality of this volume make it indispensable to biogeographers.

The relationship between systematics and biogeography is a recurring issue in both of these volumes. Croizat himself had little interest in the theory of systematics and it was only with the rise of phylogenetic systematics, now transformed to cladistics, that vicariance biogeography came into its own. The importance of phylogenetic analysis to biogeographical enquiry is now generally accepted.

The culmination, or reductio ad absurdum depending on one's viewpoint, of syntheses between cladistics and biogeography is provided by the book written by Nelson and Platnick. Both of these authors, individually and as a set, have written prolifically on the theory of systematics and biogeography, and it is therefore invaluable that they should have consolidated their views into a single testament. Systematics and Biogeography is divided into three unequal parts of uneven value - Form (systematics), Time (ontogeny, phylogeny, palaeontology) and Space (biogeography) - and is concerned with the theoretical structure of

comparative biology and the nature of our knowledge of organismic diversity. In a work laying much stress on methods, it is perhaps ironical that I find myself in agreement with its main conclusions while finding the philosophical and logical arguments leading to these conclusions naive.

In its treatment of biogeography we are taken beyond classical vicariance and the multiple sister-group approach of Hennig and of Brundin to a detailed analysis of organism and area cladograms, their comparison and congruity. The rigorous methods of comparing and summating cladograms, branching diagrams of relationship, yield a truly novel approach whose validity I would not question within the domain of its applicability, which concerns areas of endemism and their interrelationships. But species-level disjunctions, active or passive dispersal, extinction and non-allopatric speciation are all part of the history of life and cannot be legislated out of biogeography. Yet I look forward to the new rigour and energy that will surely be stimulated in comparative biology by this book.

Because of the importance of cladograms, the theoretical arguments behind the systematic sections of Systematics and Biogeography achieve a special significance. Here I find much with which to disagree. These sections are a detailed exposition of a particular or, some will say, narrow point of view. Impunitum numquam beneficium is the motto heading the book, but the authors need not fear that they will lack critical comment. Quieta movere magna merces videbatur may well prove to be their Sallustian refuge.

As a theoretical treatise the book is much concerned with the notions of order, existence and of relationship. The core of the approach, component analysis, involves the contention that cladograms are sets of phyletic trees only one of which is topologically equivalent to the cladogram, and it is cladograms, divorced of evolutionary implications, which have the greater generality and testability (propositions which I would deny) and which thus form the basis of systematic analysis.

Much of the early part of the book concerned with the justification cladograms as assessments of the order nature, an order which presupposes the existence of some sets (taxa) and denial others. But if we abandon the theoretic expectancy of a particular hierarchic order — that is, the evolutional

background - then it must be acknowledged that in strict logic a system has all the orders of which it is capable, and that which is most familiar, or most immediately perceived, may not be the order. It was Kant's problem as to what justifies us in seeing nature as a whole that assumes the form of a logical system and its solution requires theoretical input concerning causality and not mere assessment of pattern. Cladistics as a formal system is a sterile enterprise; it becomes alive only when it deals in terms of generation and transformation, either as a result of human agency (for example the study of languages or of historical texts) or as a result of processes of nature (evolution). It follows that I find the authors definitions of cladograms as synapomorphy schemes lacking such connotations less than useful, their explicit defence of this position notwithstanding. Others will decide for themselves.

There is also a great deal of set theory in the book, but of a simplistic and misleading sort. If one rejects nominalism, and accepts that sets over which quantification is possible exist, then one cannot arbitrarily deny some and not others. If quantification were not possible over all sorts of (admittedly overlapping) biological sets, then comparative physiology, ecology and so forth would not be possible. Logically, the meiofauna is as valid a set as is Aves. The special sense of existence for the hierarchical nonoverlapping sets representing the higher taxa of biological systematics is meaningful only when causal principles of their origins are involved.

What can one make of discussions of sets that are "synonymous"? Does this mean identicality, proper inclusion? This is not always made clear, and some set definitions given in terms of homologous character states may well prove to violate the "vicious circle principle". Concepts of intensional and extensional definition, denotation and connotation, although not explicitly discussed are often confused, and we could have hoped for more profound discussions of "natural" in the sense of "natural classifications", "natural taxa" and "natural kinds". The authors seem unaware that there is a vast philosophical literature dealing with such concepts and, it seems to me, fail to appreciate that these terms have meanings more precise than those of everyday use. We are told that homology does not exist independent of synapomorphy (a clear case of putting the cart before the horse!) any more than a set exists independent of its members, yet most logicians require the null or empty set. I am tware that logicians such as Goodman efer to wholes rather than sets, preferring o do without the null set, but there is no Uttence that Nelson and Platnick have taken this particular route.

ken this particular route.

If there direct on some of the logical and the log

because the relevant sections are a very important part of the work. And because they are so lucidly written, despite some lapses into condescension, these sections will have an immediate appeal to those biologists unused to logic and philosophy. Yet they must be read critically, for if it is indeed correct to accept the main conclusions of the book while denying the argument then the philosophy and logic must be re-worked. Nevertheless, I recognize the book as a tour de force of systematic biology; in particular, the synthetic parts such as those linking

systematics and biogeography into one grand structure are masterly. And even if in the historical sections scant attention has been made to my heroes, Kant and Goethe—whose notions of natural order are surely relevant to this book—I would still willingly sing with the angels from Faust: "Wer immer strebend sich bemüht, den können wir erlösen".

# Fresh interpretation of the galaxies

Barry F. Madore

A Revised Shapley-Ames Catalog of Bright Galaxies. By Allan Sandage and G.A. Tammann. Pp.157. ISBN 0-87279-652-3. (Carnegie Institution of Washington: 1981.) \$29.

SEVERAL years ago I walked into the refrigerated plate-storage room of the Dupont telescope at the Las Campanas Observatory in Chile, only to be confronted with a yellow wall of Kodak plate boxes carrying the message "Do not use—Reserved for Allan Sandage". These were the plates that were yet to be exposed to the black skies over the Chilean Andes, and which were destined to complete A Revised Shapley-Ames Catalog of Bright Galaxies.

Nearly half a century ago, Harlow Shapley and Adelaide Ames published their now-famous list of some 1,200 galaxies. Although this was only a small subset of the galaxies observed visually by the Herschels (data from which was compiled by Dreyer in the 1888 edition of the New General Catalogue), the Shapley-Ames Catalog bore the distinction of being quantified in a dimension that transcended the NGC and set the stage for subsequent discussions of the spatial distribution and intrinsic properties of galaxies. The original Catalog was, with a fair degree of success, a complete sample of the apparently brightest galaxies to a magnitude limit of about  $m_{pg} \sim 13$ . The publication of a revised version by Sandage and Tammann is both a natural extension of this work and a bold expression of new convictions.

A Revised Shapley-Ames Catalog is not simply a listing of positions, magnitudes and classifications for the brightest galaxies, it is a personal statement about galaxies and the type of Universe they inhabit. The new Catalog contains much interpreted data, and in Sandage's own words "This Catalog is going to be controversial". Certainly, most of the controversy will arise from the distances that are hidden away in the tabulated

absolute magnitudes of Column 16. And almost as certainly we shall soon see a third edition of the *Reference Catalogue of Bright Galaxies* by the de Vaucouleurs, who, together with Corwin, aimed at providing a different interpretation of the data. The time and energy needed to follow the tortuous paths of logic encountered in determining the distances to galaxies can only leave lesser mortals following on in awe. So there is and will continue to be a widely accepted need for this type of quantitative speculation.

Still, for those wishing to strike out on their own the revised Catalog will provide a wealth of raw data. Radial velocities for all but a handful of galaxies are now available; a comprehensive reference list to the original data is graciously provided; and excellent photographs illustrate the classification system employed.

As dry as a catalogue might potentially be, there is a sprinkling of humour in the text. For example, in Table 10, describing the codes for the sources of plate material used in the galaxy typing, the Uppsala Schmidt is listed as having been used for a total of zero galaxies. One might wonder how many other telescopes should have also been included here.

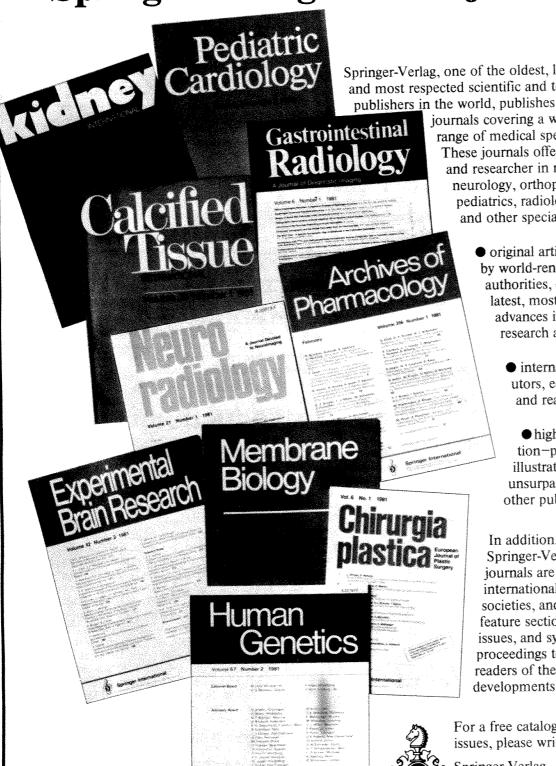

Finally, it is of interest, to me in particular, that "at least 98 per cent of the catalog galaxies can be fitted into the revised Hubble system" while "descriptive terms, such as 'pec' (peculiar), 'disrupted', 'tidal', 'ring', 'jet' and 'edge on' have been added" only in several cases. Those who see the perfection and uniformity of nature give a balance to those who study the pathology.

As for controversy, this is surely a sign of health in an active science. A Revised Shapley-Ames Catalog will be a valuable and welcome addition to the continuing search for answers in extragalactic astronomy.

Barry F. Madore is a Professor in the Department of Astronomy at the University of Toronto.

Encompassing the entire field of medicine...

# Springer-Verlag medical journals

Springer-Verlag, one of the oldest, largest, and most respected scientific and technical publishers in the world, publishes 95 medical

journals covering a wide range of medical specialties. These journals offer the clinician and researcher in nephrology, neurology, orthopaedics pediatrics, radiology, surgery, and other specialties:

- original articles, written by world-renowned authorities, on the latest, most important advances in medical research and techniques
  - international contributors, editorial boards, and readerships
  - high-quality production-particularly of illustrationsunsurpassed by other publications

In addition, many Springer-Verlag medical iournals are affiliated with international medical societies, and many publish feature sections, special issues, and symposium proceedings to inform readers of the newest developments in their field.

# Epidemiology of the townsman's blight

D.G.T. Williams

Rural Conservation in Inter-War Britain. By John Sheail. Pp.272. ISBN 0-19-8232-36-5. (Oxford University Press: 1981.) £16.50, \$49.50. The Countryside: Planning and Change. By Mark Blacksell and Andrew W. Gilg. Pp.262. Hbk ISBN 0-04-711008-2; pbk ISBN 0-04-711009-0. (George Allen & Unwin: 1981.) Hbk £13, \$35; pbk £6.95, \$17.95.

A "widespread general concern" about the scale and nature of change in the countryside is (in the words of Blacksell and Gilg) "a relatively recent post-war development"; but, as Sheail argues, "the inter-war period was so critical and innovative that precedents can be found for almost every aspect of rural planning and conservation today". Together these two books offer a useful blend of historical perspective and identification of current problems, and they remind us that there is a rich vein of source material being tapped and yet to be tapped in studies of planning and the countryside in Britain. All of the authors are geographers: their approach, however, is widely based and of value to those concerned with economics, law, administration and other aspects of a complex subject. John Sheail, who is a historical geographer, has written his book as one of the Oxford Research Studies in Geography; Mark Blacksell and Andrew Gilg, both from Exeter University, have produced their volume as one of the Resource Management Series edited by Richard Munton and Judith Rees.

As a lawyer, I found that John Sheail's book offers a revealing analysis of the complicated and hesitant movement which culminated, after the Second World War, in comprehensive planning legislation dating from 1947. Against a background of the "economic and social malaise of the inter-war years" he examines a variety of experiments in local, regional and national planning secured through the initiative of legislators, officials and private pressure groups. In the country as a whole eloquent voices raised the spectre, in the words of Geoffrey Boumphrey (in one of the contributions to Britain and the Beast in 1938, a book which is mentioned by Sheail in his concluding chapter), of

the march of an inglorious suburbia across our countryside; the wanton sterilization of much of our most productive agricultural and marketgarden land; the marring of vista upon vista, where country still remains, by the erection of unsuitable buildings, by thoughtless felling of trees, by Philistine methods of road-making and road-widening — in short the blighting touch of the townsman upon the country.

The countryside was seen as threatened as never before by the "suburbanizing trend" reflected in the spread of the towns and of townspeople, in greater mobility achieved through modern traffic and new roads, in the search for new opportunities to enjoy the countryside for recreation or to adapt the countryside (allowing, for instance, for afforestation or new industrial growth) in the public interest.

One looks in vain for a consistent or positive approach in the inter-war years to the problem of reconciling the need for change and the desire to preserve. Rural conservationists succeeded in numerous battles but seemed a long way in 1939 from winning the war against what they saw as the evil of uncontrolled infringement of the old countryside. Sheail takes a balanced and understanding view of what they sought to achieve and how far they succeeded; and it is helpful to be told in the course of his book of the circumstances in which the Town and Country Planning Act 1932 was passed; of private legislation such as the Malvern Hills Act 1924 (later to be judicially considered, incidentally, by the House of Lords in Pyx Granite Co. Ltd. v Ministry of Housing and Local Government 11960| Appeal Cases 260); of the emergence of planning consultants and of the role of geographers in land-use surveys; of the work of such bodies as the Council for the Preservation of Rural England (founded in 1926), the Forestry Commission (established by statute in 1919) and the Youth Hostels Association (founded in 1930); of planning delays in the Ministry of Health and of "a somewhat ambivalent attitude" adopted towards statutory planning by the Ministry of Agriculture; and of numerous individuals (including Evelyn Sharp) who contributed in all sorts of ways to the national and local debates and controversies of the inter-war period. Drawing upon a wide range of original material, the author - admittedly on a selective basis, for the subject is vast manages to develop a carefully structured account of the problems of planning and conservation.

The same problems are with us today, though the emphasis may have altered and the statutory framework has changed out of all recognition. In their work, Blacksell and Gilg set out to assess "the impact of the policies and plans that have proliferated during the past thirty years to guide the process of change in the rural landscape of Great Britain". They detect many inadequacies in the present system, notably the absence of co-ordinated guidance in the process of change. We are told about the work of the Ministry of Agriculture, Fisheries and Food, the Forestry Commission, the Department of the the Countryside Environment. Commission and the Nature Conservancy Council; and a number of complex issues are explored, often on a basis of original material (particularly drawn from the authors' own case studies in Devon), on such topics as the nature and measurement of land use change, planning and land use, settlement planning, settlement change, and management in the countryside. For many readers a good deal of the authors' material will be unfamiliar, but there is clearly sufficient evidence of the value of the attempt by the Resource Management Series editors to provide "an interdisciplinary vehicle for major contributions from scholars and practitioners with a wide variety of academic backgrounds".

Problems of planning and conservation obviously loom large in a small and overcrowded country such as Britain - where the population, as Blacksell and Gilg point out, rose from 38.2 million in 1901 to an estimated 56 million in 1976. A study of the countryside alone becomes even more complex when one considers issues of pollution and the new and urgent demands for energy. Within their own terms of reference, these two books are important contributions to a subject of immense difficulty, riddled with conflicting interests, and they do much to correct what has perhaps been an overemphasis on town as opposed to country planning in the system which has evolved painfully over so many vears.

D.G.T. Williams is President of Wolfson College, Cambridge, and was formerly a member of the Commission on Energy and the Environment (1978–1981) and the Clean Air Council (1971–1979).

# **Enshrouded by prose**

**David Davies** 

Cosmos and Creator. By Stanley L. Jaki. Pp.168. Pbk ISBN 0-7073-0285-4. (Scottish Academic Press: 1981.) £3.25.

PROFESSOR Jaki, a Benedictine priest with a long-time interest in the theological implications of science, has written Cosmos and Creator to make available the major points in his other books on creation "in a concise form for the wider public". In this I believe he flatters the wider public (in which I include myself) with a breadth of learning that it does not possess. A sentence such as

the presence of nominalism is merely nominal in the thought of Buridan and Oresme, while the presence there of a pre-Ockhamist traditional notion of creation is rather robust

is a typical example of some of the heavy weather encountered; I, for one, was grateful to my Fontana Dictionary of Modern Thought for providing the glossary that Jaki should have included. And even when all the words are easily understood, the author writes too often in an obscure way for my taste.

No less revealing should it seem that in Eddington's and Jeans' success of making a fad (very superficially, to be sure) [of] the inference to God from science, the most effective part was played by a factor, apparently not at all mathematical. . . .

is a bit of a mouthful, particularly as the least of the many sins for which Jaki castigates Carl Sagan is for being a "consummate artist of sentences resting on double, triple and at times quadruple negatives".

Professor Jaki carries his argument through five chapters which read like five separate essays. In the first, "An Uneasy Fashion", he traces twentieth-century fashions in cosmology and the variable willingness amongst cosmologists to look through their specialization to the question of creation and a creator. His own view is that "he who says cosmos must say Creator in the traditional sense if man's sense of reality, purpose and consistency deserve more than lip-service", and he gives short shrift to some of those who have thought differently. Of course, proponents of the steady-state theory came into this category continuous creation was "the most glaring trick ever given scientific veneer".

The next chapter begins with a text, or rather an anti-text from Anatole France — "The universe which science reveals to us is a dispiriting monotony. All the suns are drops of fire and all the planets drops of mud". Jaki rather ponderously rises to this bait by emphasizing the beauty of science, and then goes on to discuss whether the universe is necessary or merely contingent: the climate of thought in our time is not at all favourable for a recognition of reason's ability to bring within sight the contingency of the universe and its raison d'être, its having been created by a Being truly necessary.

Jaki then turns to look at creation from the viewpoint of Christian theology — not just as a vague general belief but as a dogma or proposition which demands unconditional assent. The Fontana Dictionary says that "dogma" is today "mostly used pejoratively, to mean an opinion held on grounds, and propagated by methods, which are unreasonable". I think that most scientists who wade their way through this difficult chapter, with its assertion that the first chapter of Genesis is the classic statement of the dogma of creation, will incline to the same view, and retreat to the position that religion is mainly an ethical matter and on many dogmatic matters they can at best be agnostic.

Following a chapter on the philosophical status of books, the relevance of which to the general thread of the volume escapes me even after four readings, Jaki concludes with a discussion on extraterrestrial intelligence — "this ultimate extension of Darwinism and an utterly self-defeating exercise in wishful thinking". Darwinism itself is for him a belief in the meaningless of existence and much to be reviled, although he does believe in evolution as an "imperfectly understood instrumentality of a species in the rise of another". Present-day advocates of taking ETI seriously look in it for a "final rebuttal of supernatural

revelation", and come in for some predictable stick. On the other hand, theists, for whom "intellects are a special creation of God", not a mere epiphenomenon of biochemical diversification, can keep an open mind about ETI and even look forward to a possible encounter with other intellects because both sides "will know something of a universal brotherhood based on a common dependence on the Creator".

I have read this book from a scientist's perspective, and maybe it looks different from a theologian's. But, much as it has

made me think, got under my skin and in some places stimulated me, I feel ultimately that it has helped me disappointingly little. The opacity, the dogmatism, the verbal tricks all speak to me of a failure by the author to reach out and understand his "wider public" and hold a helpful dialogue. Professor Jaki, it seems to me, wants to tell rather than to help. I think most of us need help.

David Davies is Director of the Dartington North Devon Trust. He was Editor of Nature from 1973 to 1979.

# A population problem for archaeologists

Colin Renfrew

Demographic Archaeology. By F.A. Hassan. Pp.298. ISBN 0-12-331350-3. (Academic: 1981.) \$32, £21.20.

FIFTEEN years ago, following the publication of Ester Boserup's stimulating work The Conditions of Agricultural Growth (Aldine, 1965), geographers and archaeologists fully realized that population, or population density, must no longer be regarded as a highly dependent variable, fixed or at least rigidly limited in Malthusian manner by environmental constraints. On the contrary, the mode of exploitation of resources could be varied according to need, and the level of population came to be seen rather as an independent variable (although not an unconstrained one) which would in part govern the way in which a society would intensify its agricultural production.

Since that time, demographic arguments, some of considerable sophistication, have loomed large in archaeological explanations. Their proponents have been encouraged by the new rigour of archaeological survey procedures, which have moved on from the casual serendipity of the weekend outing or the summer safari to the often exhausting demands of probabilistic sampling strategies and intensive field-walking by disciplined survey teams.

Demographic Archaeology undertakes a comprehensive review of demographic thinking and population models in contemporary archaeology. It ranges from the consideration of the population density of hunter-gatherer groups, where the context is very much one of biogeography, through the impact of sedentism and food production upon carrying capacity, and on to the emergence of complex, urban civilizations with their large population centres. As a general survey it succeeds admirably in bringing out the central role of demographic argument in much contemporary archaeological thought, and in summarizing the rather formidable range of quantitative formulations which have already been put forward.

One central weakness in the whole subject area, however, is that early population figures, for any given time and place, are extremely difficult to arrive at, based as they almost invariably are on fragmentary survey data, supplemented by the incomplete excavation of a few settlement sites. At present this often restricts an estimate of the population variable from rising beyond the purely notional.

The crucial question of estimating population size from archaeological data takes up only one 32-page chapter of Hassan's book. And while this chapter is a very competent review of what has been written, it is not a very critical one, nor does it, to my mind, bring out the still unresolved difficulties in estimating population figures with any degree of accuracy and reliability from archaeological data. Until these difficulties are overcome, the demographic explanation in archaeology must remain something of a will o' the wisp: an enticing hypothesis, the testing of which remains a frustrating task. Hassan might have dealt at greater length with this crucial problem, for it is in the improved estimation of early population figures that the future of demographic archaeology must lie, rather than in the production of ingenious theories which, however attractive and plausible, have merely the status of speculation until sustained by acceptable data from the field.

Despite this central difficulty, which is not Hassan's problem alone but one which faces all researchers, his book is undoubtedly a sustained and coherent contribution to archaeological theory. It serves to bring together a whole series of ideas never before so effectively related, and takes its place at once among the small number of books on archaeological theory which rise above mere polemic to serve as valued works of reference.

Colin Renfrew is Disney Professor of Archaeology at the University of Cambridge.

# Of Oxygen Fuels and Living Matter Part 1

edited by G. Semenza, ETH - Zentrum, Zurich, Switzerland

The Series "Evolving Life Sciences" is concerned with the development of the relatively new disciplines such as biochemistry, biophysics, molecular biology and related sciences. Each of the volumes in the series will consist of papers written by or about prominent representatives of these new biological sciences, presenting personal accounts of their scientific lives illustrated by a selection of their papers reproduced facsimile. These autobiographic and biographic chapters will convey to the reader lively, albeit at times subjective, views both on the scientific development and on the social environment at the time. The emphasis in the first volume of the series is on bioenergetics and metabolism.

Evolving Life Sciences, Recollections on Scientific Ideas and Events Vol. 1

Contents: Series Preface; Bioenergetic Aspects of Unity in Biochemistry: Evolution of the Concept of Ligand Conduction in Chemical, Osmotic, and Chemiosmotic Reaction Mechanisms (P. Mitchell); Keilin, Cytochrome, and the Concept of a Respiratory Chain (E.F. Hartree); An Autobiographical Sketch Related to my Efforts to Understand Oxidative Phosphorylation (P.D. Boyer): Resolution and Reconstitution: A Dual Autobiographical Sketch (E. Racker and F.W. Racker); From Respiration of Muscle to Muscle Actin (F.B. Straub); Author Index

# **Applied Geophysics** Introduction to Geophysical Prospecting 2nd Ed. (completely revised)

by G. Dohr, Preussag AG, Erdol und Erdas, Arndtstrasse 1, D-3000 Hannover 1

Geophysical exploration is today one of the most important tools in the supply of energy and raw materials to the technical world. The scope of applied geophysics includes prospecting for oil, gas and mineral ores, as well as the problems of hydrology, structure foundation and the protection of the human ecosystem against pollution. This book covers the latest developments with special emphasis on modern data processing, filling a gap between textbooks on one side and highly specialized journal articles and reviews on the other.

240pp

(paper only) \$24.50/£9.90

# **Energy:** Hydrocarbon Fuels and Chemical Resources

by D.K. Rider, Bell Laboratories Inc

Provides a descriptive treatment of the current energy situation and fuel and chemical feedstock options for the future. It explores the pros and cons of fossil resource conversion to fluid hydrocarbons and points out the limitations of renewable resources. Two appendixes cover abbreviations, acronyms, and definitions to ease technical language difficulties.

June 1981 0471 05915 3

506pp \$46.50/£25.85

# Modernization of Agriculture in **Developing Countries:** Resources, Potentials and Problems

by I. Arnon, Hebrew University, Jerusalem; Settlement Study Centre, Rehovot; and Volcani Centre of Agricultural Research, Bet-Dagan, Israel

The overall objective of this book is to give an up-to-date, comprehensive review of the experience gained in the process of modernizing agriculture in the developing countries, and in coping with the problems that arise following the adoption of new technologies.

September 1981 0471 27928 5

590pp \$66.50/£29.50

# **Marine Electrochemistry:** A Practical Introduction

edited by M. Whitfield, Marine Biological Association of the United Kingdom, Plymouth,

and D. Jagner, Department of Analytical Chemistry, University of Goteborg, Sweden

An introductory section provides background information on the nature of seawater, the classification of electrochemical techniques, the design of electrochemical instrumentation for field studies and the use of microcomputers in analytical procedures. The main section of the book covers in detail the application of conductimetry, ion-selective electrode potentiometry, amperometry (for oxygen determination), electrodeposition and polarography and voltammetry to sea water

December 1981 0471 27976 5

544pp \$65.00/£27.50

# **Aquatic Pollution An Introductory Text**

by E.A. Laws, University of Hawaii

Reviews basic knowledge and general ecological principles relevant to water pollution and toxicology. It presents both the need for economic growth and preservation of the environment, particularly in its treatment of such subjects as pesticide use, sewage treatment, and thermal pollution. It emphasizes that some forms of pollution represent valuable resources when properly managed, and that pollution control usually involves a trade-off between environmental conservation and industrial? agricultural growth.

April 1981 0471 05797 5

49600 \$45.15/£25.10

# Air Pollution Control, Part 4

edited by G.M. Bragg, University of Waterloo, Canada, and J. Strauss

Covers in detail the effects of urban meteorology on air pollution distribution, effects of air pollutants on plant life. metals, and coatings; and pollution control and equipment, including mist eliminators, filtration, and incineration.

# Nature announces the first wall chart showing how the U.S. runs its science ... shows who makes U.S. science decisions who gets the money, and how it's spent

If you're involved in making decisions about science, or if you're looking for your share of science funding, you need Nature's new 1981 guide to how the nation spends its science dollars and who controls that money.

Compiled by Nature from literally hundreds of sources, the wall chart offers data on actual dollars spent on science by government agencies, industry, foundations, universities, research and medical centers. The chart lists key U.S. government policy makers, with their addresses and phone numbers.

Most significantly, the chart shows the interlocking relationships within the science, engineering, and medical establishments.

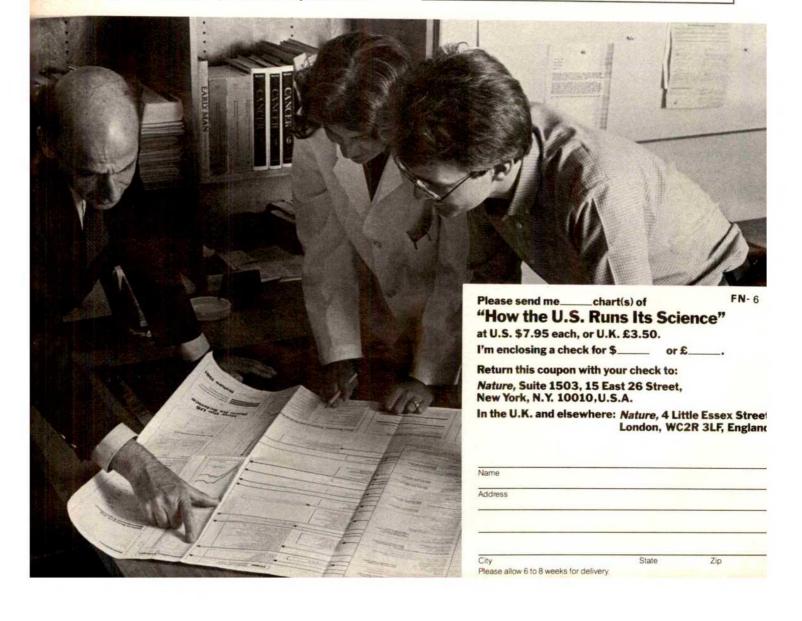

Designed as a fold-out that you can carry to meetings, or for hanging as a 2 x 3 ft. wall poster for permanent reference, the chart enables you to answer questions that

might otherwise take weeks of research to dig out. Compact, color-keyed, and handy, it will be an enormous aid to you and your colleagues. We strongly urge you to order sufficient copies to cover the needs of your entire staff or department.

# "How the U.S. Runs Its Science"

-another authoritative publication from Nature, for more than 100 years, the world's most respected source of science

# TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY

# **VOLUME ONE** TOPICS IN NUCLEIC ACID STRUCTURE

**Edited by STEPHEN NEIDLE** 

Department of Biophysics University of London Kings College

1981; £20.00; 221pp; ISBN 0 333 266781

Introduction to the series — W. Fuller & S. Neidle; Preface; Conformational principles of nucleic acids — H.M. Berman; Introduction to the series — W. Fuller & S. Neidle; Preface; Conformational principles of nucleic acids — H.M. Berman; Crystal structures of fragments of DNA and RNA — H.M. Berman & H.S. Shieh; NMR studies of oligonucleotides in solution — R.H. Sarma & M.M. Dhingra; The secondary structures of polynucleotide chains as revealed by x-ray diffraction analysis of fibers — S. Arnott; Transfer RNA: crystal structures — S.H. Kim; The solution structure of transfer RNA studied by proton NMR — B.R. Reid; Eukaryotic chromatin — D.M.J. Lilley; Oligonucleotide and polynucleotide-drug complexes in the crystalline state — S. Neidle; Oligonucleotide and polynucleotide-drug complexes in solution as investigated by NMR — T.R. Kright Index investigated by NMR - T.R. Krugh; Index.

This volume systematically details the recent data on structural aspects of oligonucleotides, transfer RNAs, polymeric nucleic acids and chromatin. Each category is described both in terms of x-ray crystallographic and solution NMR data. A standard and rational system of nomenclature is used throughout.

# **VOLUME TWO TOPICS IN NUCLEIC ACID STRUCTURE PART 2**

**Edited by STEPHEN NEIDLE** 

Summer 1982; c£24.00; c208pp; ISBN 0 333 315553

# CONTENTS

Theoretical calculations of nucleotide and nucleic acid conformation — W.K. Olson; NMR studies of oligonucleotides — D.J. Patel et.al.; The roles of water in maintaining nucleic acid structure — W. Fuller; Conformational trends among chemotherapeutically important nucleosides — G.I. Birnbaum & D. Shugar; Recent crystallographic studies of transfer RNAs — T. Wright; Hairpin loops and folds in DNA — D.M.J. Lilley; Crystallographic studies on protein-nucleic acid interactions — A. McPherson; Protein and peptide-nucleic acid interactions — C. Helene, J.J. Toulem & T. Montenay-Greetier; The belicity of DNA — D. Rhodes Garestier; The helicity of DNA - D. Rhodes.

This second volume in the 'Topics in Molecular and Structural Biology' Series extends the approach given in Volume One to related areas of current interest and activity.

The themes of nucleoside, oligonucleotide and nucleic acid conformation are explored in chapters on theoretical approaches to structure, NMR studies, structure-function relationships of biologically active nucleosides, and the all important influences on structure of water and other environmental factors. Recent crystallographic studies on transfer RNAs and on protein-nucleic acid interactions are reviewed. The theme of nucleic acid recognition is further explored by a chapter covering the extensive solution data available for protein and peptide-nucleic acid binding, including recognition of

nucleic acids damaged by external agents.

Much vital information on the structure of DNA in solution can now be obtained by modern biochemical and genetic manipulation techniques. These are reviewed in chapters discussing recent advances in our knowledge of DNA helicity. and on the propensity of DNA to form hairpin loops.

Taken together, these two volumes form a useful supplementary text for advanced undergraduate and research work in biophysics, molecular genetics and pharmacology. They are the first volumes to bring together in an integrated and in depth manner, all the important aspects of current studies on structural aspects of nucleic acids.

Aims and Scope

Toxicology is the study of the reactions, both adverse and compensatory, of living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where it has a direct significance for man, and studies on man himself. These studies may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding of the action of noxious substances in the body and of means to counter their effects. All papers will be subject to peer review.

# **CONTENTS VOLUME ONE NUMBER ONE Editorial**

A Message from the Chairman of the Editorial Board — Professor Roy Goulding.

Human Toxicology: Major Issues Illustrated in the First Issue — Professor Paul Turner.

# **Papers**

# UNIVERSITY OF TEXAS

# PROJECT ENGINEER 300-inch Telescope

McDonald Observatory is seeking applications from senior level engineers (especially Mechanical Engineers) interested in undertaking leading role in development of 300-inch monolithic primary, optical telescope.

Successful candidate will hold title of Special Research Associate and form the nucleus of a team respon-sible for final specification and design of the total observing system, including telescope, housing, aluminizing facility and control systems.

Position requires experienced, versatile individual with demonstrated ability to develop cost-effective solutions to technical and engineering management problems involved in the construction of large, dynamic mechanical assemblies.

Pending completion of funding, an appropriate candidate could assume role of Chief Project Engineer for the multi-year construction effort on this

Send résumé including salary history to Dr Harlan Smith, Director, UT McDonald Observatory, Austin, Texas 78712 (512) 471-4461. We are an equal opportunity/affirmative action employer. (NW172)A

# CAMBRIDGE UNIVERSITY POST DOCTORAL **POSITION**

to work in the physiology, biophysics or morphology of local interneurones in the central nervous system of Experience with insects. neurobiological or cell biological techniques essential. Salary between £6,475 and £7,290 depending on age and experience. One year appointment. It is hoped it will be renewable if funds available.

Send details of experience and names of 2 referees to Dr M Burrows, Zoology Department, Street, Cambridge CB2 3EJ. (083)A

### POST DOCTORAL **POSITION**

Available immediately in Biochemical endocrinology to study the regulation of estrogen Biosynthesis in human tissues. Background in protein purification, immunochemical techniques or primary cell culture preferred. Salary \$13,000.

Send résumé and three reference letters before Jan 15 to: Dr F Bellino, Dept Biol Sci, 336 Cooke, SUNY/Buffalo, Buffalo NY 14260. An Equal Opportunity/Affirmative (NW173)A Action Employer.

# IMMUTRON INC.

# ALLERGY RESEARCH

Positions are now open for Immunochemists (PhD) in the following areas: allergen specific IgE, basophil histamine release, allergen qulaity control and standaridization.

Candidates should have a strong background in at least one of these

Send CV to Irene B Haydik MD, Immutron Inc., Monrovia Ave, Newport Beach, Ca 92663 (NW171)A

# RESEARCH **BIOCHEMIST, Ph.D.**

The Lilly Research Laboratories, a leader in pharmaceutical and agricultural research, seeks a biochemically oriented scientist to expand its fermentation screening program. To be considered for this position, applicants must have a Ph.D. in biochemistry, enzymology, or a related area. The successful applicant will conceive, develop, and implement novel screening methods for the detection of nonantimicrobial activities in fermentation broths. These methods may include enzyme inhibition screens, tissue culture, or other techniques short of whole animal studies. The position requires an ability to work in a multidisciplinary environment that encompasses chemical, biochemical, and biological skills. A working knowledge of mammalian physiology would be a definite asset.

Eli Lilly and Company offers an excellent compensation program and apportunities for professional growth. Qualified individuals should send their résumé in confidence to

# THE ROWETT RESEARCH INSTITUTE Bucksburn, Aberdeen AB2 9SB

# Appointment of DIRECTOR

Applications are invited for the post of Director of the Institute on the retirement of the present Director, Sir Kenneth Blaxter, FRS. The appointment can be taken up towards the end of 1982.

The main purpose of the Institute is to conduct research in animal nutrition and allied sciences, including the study of metabolic processes within animals, with particular emphasis on farm livestock. Some of this research also has relevance to human nutrition, and there may be a limited increase in this work.

The research programme is commissioned by the Department of Agriculture and Fisheries for Scotland, with advice from the Agricultural Research Council. The Institute forms part of the Agricultural Research Service and has close links with the University of Aberdeen, particularly its Schools of Medicine and Agriculture.

The Director is responsible to the Governing Body for the Administration of the Institute and management of the research programme which consists of eleven divisions. The director provides scientific leadership to the staff which numbers about 315, of whom 200 are in the scientific category. It is usual for the Director to be appointed Consultant Director of the Commonwealth Bureau of Nutrition, which is located at the Institute.

The post is graded Chief Scientific Officer (Lower Band) and there is a non-contributory superannuation scheme. During the tenure of the appointment a detached house sited within the Institute campus may be rented by the successful candidate.

QUALIFICATIONS: Applicants should have appropriate qualifications, a distinguished record of personal research and experience of management of research.

Further particulars are available from the Secretary of the Institute, to whom applications should be submitted with full curriculum vitae and the names of three referees. Closing date; 5th February 1982.

# PUBLIC HEALTH LABORATORY SERVICE BOARD

CENTRAL PUBLIC
HEALTH LABORATORY
VIRUS REFERENCE LABORATORY
BIOCHEMIST

A postdoctoral biochemist is required in the Virus Reference Laboratory to join a group of microbiologists working on viral gastroenteritis. The work will involve the biochemical characterisation of viruses associated with nonbacterial gastroenteritis and a study of the possible relationship of the human agents with viruses of veterinary importance. Experience in the purification of viruses would be an advantage.

The successful candidate will be appointed as a Senior Grade Biochemist according to qualifications and experience; the salary scale for which is £8,691—£11,073 inclusive of London Weighting.

NHS Terms and Conditions of Service apply.

Applycations to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Telephone number 01-205 7041.

Closing date: 8th January 1982. (076)A

# UNIVERSITY COLLEGE OF NORTH WALES, BANGOR RESEARCH ASSISTANT BACTERIAL PLASMID ANALYSIS

Applications are invited for the above post, to collaborate with Dr N J Grinter (ext 359) on studying mechanisms governing the accurate partitioning of bacterial plasmid molecules at cell division, including the isolation and mapping of plasmid mutations and DNA base sequence analysis.

Applicants for this post, which will be for one year in the first instance (renewable for a further two years) and within the range: £5,285—£7,700 per annum, should be at least biological-science graduates, with a knowledge of bacterial genetics and the biology of bacterial plasmids. Experience of recombinant DNA technology would be an advantage.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, by not later than 11th January, 1982. (057)A

# COLLEGE OF VETERINARY MEDICINE AND BIOMEDICAL SCIENCES Colorado State University

DEPARTMENT OF MICROBIOLOGY

### HEAD

Applications and nominations are invited for the position of Head of a progressive and diversified Department. Qualifications required are an earned doctoral degree (PhD, DVM, MD or equivalent), distinguished achievement in research and teaching and demonstrated capacity for leadership. Research interests of the Department include virology, immunology, bacteriology and mycology at the molecular, veterinary, medical and environmental levels. The Department is responsible for undergraduate, graduate and veterinary programs in microbiology. Deadline for receipt of applications is February 15, 1982.

Candidates should submit a curriculum vitae to; D Robertshaw, Chairman, Search Committee, Department of Physiology and Biophysics, Colorado State University, Ft. Colins, Colorado 80523. Colorado State University is an EEO/AA employer. E O Office, 315 Student Services Building.

(NW167)A

PHYSIOLOGY Faculty Position: Assistant Professor tenure-tract position for July, 1982. An interest and post-doctoral research experience in gastrointestinal physiology, particularly in peptides of the gastrointestinal tract and their regulatory role, is preferred. Candidates will be expected to teach physiology of the digestive tract to medical students and to participate in graduate courses and to develop an independent research program. Applicants should submit curriculum vitae, reprints and statement of research interests, and teaching experience, and have three letters of recommendation sent to: Dr Robert E Forster, Chairman, Department of Physiology, School of Medicine, University of Pennyslvania, Philadelphia, Pa 19104. An equal opportunity/affirmative action employer. (NW164)A

# THE INSTITUTE OF DERMATOLOGY (University of London) ELECTRON MICROSCOPY UNIT

requires a pre- or post-doctoral Research Assistant to join a small team investigating mechanisms in blistering diseases. Methods in use include transmission EM, immunohistochemistry and cell culture.

The post will be for 2 years in the first instance. Salary according to age and experience (1A scale for applicants with PhD).

Applications, including CV and names of two referees to: Dr R A J Eady, Institute of Dermatology, Homerton Grove, London E9 6BX. (Tel: 01-985 7061 ext 66) from whom further details may be obtained. (074)A

# UNIVERSITY OF LEICESTER DEPARTMENT OF GENETICS POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from persons with a good background in biochemistry or molecular genetics for a postdoctoral research position financed by a Cancer Research Campaign award. The project will be concerned with the characterisation of error-prone DNA replication in E. coli induced by carcinogens or UV-irradiation. This will involve the use of cloning teachniques, in vitro DNA replication systems and enzyme purification procedures. The work is likely to involve close collaboration with research groups in the Department studying other aspects of the SOS response in E. coli and with groups studying the control of and mechanism of plasmid DNA systhesis using an in vitro system.

The appointment will be tenable for up to 3 years from 1 January 1982 or as soon after as can be arranged. Starting salary £6,880 (at age 26) per annum with full superannuation provision.

Applications with names of two referees to Dr I B Holland, Department of Genetics, University of Leicester, Leicester LE1 7RH.

(043)A

# **ORGANIC CHEMIST**

A post doctoral research fellow is required for one year to join a team studying the chemistry of tobacco. The work offers interesting structural and synthetic problems in the natural product field, which requires knowledge of both modern spectroscopic and chemical methods and advanced separation procedures.

The annual salary is £11,000 and assistance will be given with relocation expenses and in obtaining accommodation.

Please, write to Professor C R Enzell, Research Department, Swedish Tobacco Company, PO Box 17007, S-104 62, Stockholm, Sweden, (Telephone 08-69 09 00) enclosing a brief curriculum vitae and references, before January 20, 1982. (W537)A

# UNIVERSITY OF SASKATCHEWAN

DEPARTMENT OF BIOLOGY

Postdoctoral position available to investigate the liposome-mediated transfer of chromosomes into auxotrophic cells of *Datura*.

Candidates should have a strong background in genetics and cell biology and be trained in the use of plant cell culture techniques.

The position is available immediately for a one-year term (renewable for a further two years) at a salary of \$16,380 Can.

Candidates should send curriculum vitae and two letters of recommendation to Dr John King, Department of Biology, University of Saskatchewan, Saskatoon, Sask, Canada S7N OW0. (NW153)A

# THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN **EXPERIMENTAL NUCLEAR** STRUCTURE PHYSICS

Applications are invited for this post, Applications are invited for this post, tenable from February 1, 1982 for up to three years. The appointee will pursue research at the Nuclear Structure Facility, a 30 MV tandem Van de Graaff which is nearing completion at the Daresbury Laboratory. Duties also involve assistance with the commissioning of the isotone separator at the the isotope separator at the Daresbury Laboratory.

Applicants should hold a PhD and have an aptitude for research in experimental physics. Initial salary pa; £7,290.

Applications, with full CV and names of two referees to: Dr R Chapman, Department of Physics, the University, Manchester M13 9PL from whom further details may be obtained. (075)A

# NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING MICROBIOLOGY DEPARTMENT A SCIENTIFIC OFFICER

is required for a period of 2 years to assess and develop rapid sensitive methods for detecting any traces of antibiotic in milk. A wide range of microbiological, immunological and radiometric techniques will be involved.

Applicants should have a first or second class (2:1) honours degree in Microbiology, Biochemistry or Immunology.

Appointment, for a limited period of only two years, will be as Scientific Officer; salary scale £5,176 to £6,964. Non-contributory superannuation.

Apply in writing, enclosing full cv, to the Secretary, NIRD, Shinfield, Reading RG2 9AT.

Quote reference 81/30. (061)A

# **MOLECULAR CELL BIOLOGY PREDOCTORAL FELLOWSHIPS**

The Graduate Program in Molecular Cell Biology invites applications from highly qualified students interested in an interdisciplinary PhD program. Major areas of emphasis include animal virology, bacterial and somatic cell genetics, cancer biology, cellular immunology and immunochemistry, connective tissue and protein biochemistry, infectious diseases and host defense, membrane biochemistry, nucleic acid synthesis, and research involving the cause and prevention of dental caries.

All students admitted to the program receive stipends of \$6,300 plus tuition and fees per year. After admission to candidacy the stipend is increased to \$7,000 per year.

Contact: Dr Roy Curtiss III, Director of Molecular Cell Biology Graduate Program, Department of Microbiology, University of Alabama in Birmingham, Birmingham, Alabama 35294. (NW165)A

# THE UNIVERSITY **OF TASMANIA CHAIR OF CHEMISTRY**

Applications are invited for appointment to the Chair of Chemistry, which will become vacant on the retirement of Professor H Bloom on 31 December 1981.

Applications are invited from candidates in any field of Chemistry.

The present professorial salary is \$A41,509 pa.

Candidates who wish to apply should in the first instance write to The should in the first instance write to The Registrar, University of Tasmania, Box 252C, GPO, Hobart, Tasmania, Australia 7001, or to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, to obtain a detailed statement of the conditions of appointment and conditions of appointment and application forms.

Applications close on 19 February (078)A

# UNIVERSITY OF ESSEX DEPARTMENT OF BIOLOGY RESEARCH OFFICER

Applications are invited for the post Research Officer funded by the on Research Officer funded by the Science and Engineering Research Council (salary on Range IB £5,285 — £7,700). The appointment to commence in January 1982. The research project is planned to develop a representation planned to develop a transformation system in Aspergillus nidulans. This system will be used for cloning, recombination studies and identification of transposable sequences. The successful applicant will work under the direction of Dr C Scazzocchio and will be eligible to read for a higher degree. Candidates requiring further information should contact Dr Scazzocchio. Telephone: Colchester (0206) 862286 ext 2427.

Applications in writing as soon as possible quoting reference AG/131/ N/S to Dr C Scazzocchio, University of Essex, Wivenhoe Park, Colchester CO43SO.

# DIRECTOR

The Herbert Whitley Trust and the Paignton Zoological and Botanical Gardens Ltd will shortly require a Director owing to the forthcoming retirement after some 25 years' service of the Managing Trustee and the General Manager.

The Trust, a registered Charity, owns the Zoo, the Slapton Ley Nature Reserve and other properties.

Candidates should have zoo experience, scientific training, commercial flair, an interest in education and the ability and determination to take forward two well respected organisations to even greater prestige and value to the community in the next 20 or 30 years.

Apply in writing to Managing Trustee, Herbert Whitley Trust, Primley Estate Office, 190 Totnes Road, Paignton, Devon TQ3 3SB (tel. Paignton (0803) 558189).

(071)A

# CELLTECH

# ASSAY SYSTEMS RESEARCH

Celltech is a new British Company backed by Government and City financial institutions, and is dedicated to the exploitation of discoveries in the field of biotechnology. Celltech is currently situated in Slough, but will transfer to a new permanent location at a later date.

Two appointments are to be made in a newly formed research group investigating novel immunoassay systems.

Ref 121 PHD: Senior Scientist grade required, with 1-3 years post doctoral experience in the field of immumoassay. The successful candidate would be expected to show an innovative approach to the development of new assay systems which exploit the advantages of monoclonal antibodies.

Ref 122: Senior Technician with HND, M I Biology of similar qualifications and several years experience in immunological R and D, required to participate in the development of novel immunoassay systems.

Celltech offers excellent salaries, subsidised lunches, contributory pension scheme and 4 weeks annual holiday.

Applicants should send a cv to the Personnel Department, Celltech Limited, 244 Bath Road, Slough, Berkshire. (080)A

# THE CALIFORNIA INSTITUTE OF **TECHNOLOGY**

invites applications for

# JUNIOR FACULTY POSITIONS IN ASTRONOMY

Caltech wishes to appoint two tenure track assistant professors, although in exceptional circumstances successful candidates may be offered associate professorships without tenure. The major research interests of candidates should be in observational optical or infrared astronomy. They will be expected to devote the major fraction of their effort to observational work in instrument development at Palomar Observatory which is operated by Caltech.

Applications should include (1) a description of educational background; (2) a résumé of research and teaching experience; (3) a list of all publications; (4) copies of all manuscripts submitted for publication but not yet published; (5) a statement of current research interests and future research plans. The applicant should ask three scientists who know him/her personally to send letters of evaluation directly to Professor M H Cohen, Executive Officer for Astronomy, California Institute of Technology, Pasadena, CA 91125. Completed applications and letters of evaluation should be received by March 1, 1982; appointments will be made as soon thereafter as circumstances permit.

Caltech is an Equal Opportunity Employer with an Affirmative Action Program. We encourage applications from qualified women and members of minority groups. (NW166)A

# COMMONWEALTH AGRICULTURAL BUREAUX Three vacancies for **ENTOMOLOGISTS** in the COMMONWEALTH INSTITUTE OF **ENTOMOLOGY** (IDENTIFICATION

SERVICE)

Duties: To carry out identifications, and investigate the taxonomy, of insects in either the Hemiptera, Hymenoptera or Diptera. Appointees will be members of the Institute's Identification Service located in the British Museum (Natural History) in South Kensington, and will work under the supervision of senior taxonomists as appropriate. Posts probationary for the first year.

Qualifications: A degree or equivalent qualification in a relevant subject with emphasis on entomology, and evidence of an interest in, and aptitude for, taxonomic work.

Selary: In the Taxonomist (£5,176 - £6,964) or Higher Taxonomist (£6,530 - £8,589) scale, plus Inner London Weighting of £1,087 per annum; possibility of eventual progression to higher scales. Starting salary according to age, qualifications and experience.

Application forms and further particulars from the Director, Commonwealth Institute of Entomology 56 Queen's Gate, London SW7 5JR, England.

Closing date for receipt of applications: 31st March 1982.

(063)A

# SHARE OUR FUTURE

# **RESEARCH MANAGER**

Edmonton — This is a senior management position with responsibility for developing a research support capability for the Department. You will work in an active team environment to develop and manage research programs and projects relevant to Departmental policy. You will review and evaluate research proposals, and reports, communicate research information to Departmental staff and represent the Department on University, government and industry committees. You may also undertake research in your area of specialization. Qualifications: PhD in plant physiology ecology and considerable experience in environmental research and management plus a good general knowledge of environmental sciences and problems, specifically effects of pollutants on ecosystems. Equivalencies will be considered.

Salary: Up to \$42,696. Closing Date: Dec. 30, 1981. Competition // EV M642-4. Environment

Please send an application form or resume quoting competition number to:

Alberta Government Employment Office 5th Floor, Melton Building 10310 Jasper Avenue Edmonton, Alberta T5J 2W4

(NW174)

# THE UNIVERSITY OF LEEDS DEPARTMENT OF RADIOTHERAPY

Applications are invited for a post of POSTDOCTORAL

RESEARCH FELLOW in the Department of Radiotherapy, Cookridge Hospital for work on biology and immunology of tumour

cells involving the use of flow cytometric techniques.

A good honours degree is biochemistry/biology and a PhD in biochemistry or cell biology are

The post is available from 1 January 1982 for a fixed period of up to three

required.

Salary on the IA scale for Research and Analogous Staff (£6,070 — £10,575), according to age, qualifications and experience.

Informal enquiries may be made to Dr J E D Dyson at Cookridge Hospital, Leeds (telephone Leeds 673411 ext 219).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 108/1/D. Closing date for applications 7 January 1982. (081)A

# SCLAVO/ITALY POSITIONS IN MOLECULAR BIOLOGY

Sclavo, an ENI subsidiary, is a company specialized in the production of biological products for medical application.

Headquarters, plants and applied research facilities are located in Siena in a very pleasant situation, and laboratories are modern and well equipped. The company is now organizing a separate center for basic research. This center includes divisions of molecular biology, biochemistry, cell biology and immunology.

Positions are available in the department of Molecular Biology which is interested in gene expression in mammalian cell systems. Applicants are expected to have a productive research record in the fields of nucleic acids, genetic engineering, cell transformation or virology, to join ongoing research programmes on mammalian cell differentiation. Salaries will be commensurate with experience and seniority of the applicants, in accordance with international standards.

Send résumé to: Prof. Paolo Neri, ISVT Sclavo SpA, Via Fiorentina, 1, 53100 Siena, Italy. (W538)A

# GLOUCESTERSHIRE AREA HEALTH AUTHORITY

# MEDICAL LABORATORY SCIENTIFIC OFFICERS/JUNIOR

Medical Laboratory 'B'
Gloucestershire Chemical Pathology Service

The Chemical Pathology Department is sited in and serves the two district general hospitals in Cheltenham and Gloucester covering a population of 500 000

The laboratories are well-equipped and offer a comprehensive service. Further study is encouraged.

Applicants for the Medical Laboratory Scientific Officer grade must hold an HNC/HND in MLS (clinical chemistry) or appropriate science degree and be registered with the Council for Professions Supplementary to Medicine.

The Junior 'B' grade is open to holders of an ONC/TEC in Sciences (medical laboratory science variant) or science degree. Informal visits are welcomed by arrangement.

Application forms and further information may be obtained from Mr I.R. Holliday, Principal Medical Laboratory Scientific Officer, Department of Clinical Pathology, Gloucestershire Royal Hospital, Great Western Road, Gloucester GL1 3NN. (067)A

# COLLEGE OF ENGINEERING AND APPLIED SCIENCE

The University of Wisconsin-Milwaukee invites applications and nominations for the position of Dean of the College of Engineering and Applied Science. The University, with 27,000 students, is one of two doctoral level campuses in the University of Wisconsin System with a strong emphasis on graduate education and research. UWM is located in the heart of the state's largest metropolitan area and the center of its manufacturing and business enterprise.

The College of Engineering and Applied Science has five departments: Civil Engineering, Electrical Engineering and Computer Science, Industrial and Systems Engineering, Materials Engineering, and Mechanical Engineering, offering programs leading to bachelor through doctoral degrees.

The Dean is responsible for administrative leadership of the College. Duties include the continuing development of ongoing research programs, liaison with the industrial community, and promotion of continuing professional education programs.

Candidates should have a doctoral degree in engineering or in an applied science or demonstrated equivalent, and qualifications for a tenured faculty appointment in one of the departments of the College. The position will be available by the Summer of 1982.

All nominations and applications for the position (including résumé and the names of at least three references) should be postmarked by March 1, 1982, to: Dr Robert C Eidt, Chairperson, Search and Screen Committee, The University of Wisconsin-Milwaukee, Department of Geography, Milwaukee WI 53201.

An Equal Opportunity/Affirmative Action Employer. (NW159)A

# UNIVERSITY OF ST ANDREWS

DEPARTMENT OF PHYSIOLOGY & PHARMACOLOGY

# POSTDOCTORAL NEUROBIOLOGIST

Applications are invited for a post of Postdoctoral Research Assistant to work on dendritic sprouting in invertebrate neurones. The work is financed by the SERC for three years from March 1982 or as soon as possible thereafter. Salary within the range £6,070 to £6,880 per annum, according to age and experience, plus superannuation.

For further information about the work please contact Dr R M Pitman, Department of Physiology and Pharmacology (telephone St Andrews 76161 ext 7209).

Applications with curriculum vitae (two copies preferably in typescript), and the names of three referees should be submitted to the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ by 15th January, 1982.

. (077)A

# I.L.R.A.D. (Nairobi)

Applications are invited from suitably qualified candidates for the post of:-

# POST DOCTORAL FELLOW Ref No PDF/L4/81/1

A position is available for a post-doctoral fellow to work with the Immunobiology Unit on the definition of cells of the bovine immune system. Applicants must have experience in preparing, maintaining and testing, functional T-cell, natural killer cell etc., clones from a mammal.

The successful applicant will be expected to work closely with other members of the unit who have produced monoclonal antibodies against bovine B-cell T-cell and macrophage surface membrane determinants. The studies are directed towards understanding bovine immune response against African trypanosomes and *Theileria* infected bovine cells. This is an international position, the salary will be paid in U.S.\$ and the successful applicant will be assisted with moving expenses.

Applications identified with Ref No including C.V., summary of PhD thesis, and three references should be sent to:-

Chief Personnel Officer, I.L.R.A.D P.O. Box 30709, NAIROBI, Kenya

Closing date: 7/1/82

(W528)A

# UMIST

DEPARTMENT OF BIOCHEMISTRY
Ref: HIO/149/AI
POST-DOCTORAL
PHARMACOLOGIST/
NEUROPHYSIOLOGIST

required to work on a two year industrially funded project investigating nocrotransmitters and receptors with a view to developing new insecticides. Experience in intracellular recording would be an advantage. Informal enquiries to Dr N M Tyrer (061 236 3311 ext 2115 or 2111)

Salary will be on the scale £6,070 — £7,700 per annum.

Requests for application forms, quoting the above reference should be sent to the Registrar, Room B6, UMIST, PO Box 86, Manchester M60 1QD. The closing date is 31 December, 1981. (082)A

# ROSWELL PARK MEMORIAL INSTITUTE MOLECULAR IMMUNOLOGY

a comprehensive cancer research center has available three-tenure track positions which are open in the Department of Molecular Immunology. The department is expanding into the areas of idiotype manipulation and recombinant DNA technology. One of the positions is at the senior, (full professor equivalent) level and two are at the junior level. No formal teaching is required at the Institute, but graduate students are available through the institutional graduate program. The candidate for the senior staff position will be consulted in the selection of the junior candidates.

Applications should be forwarded to Heinz Kohler, Chairman of the Department of Molecular Immunology, Roswell Park Memorial Institute, 666 Elm Street, Buffalo, New York 14263. An Affirmative Action/Equal Opportunity Employer. (NW170)A

# POSTDOCTORAL RESEARCH ASSOCIATE

Position available immediately for a period of two years for collaborative work in the field of cell motility. Interests of the laboratory are in immunocytochemical analysis of contractile proteins in the cytoplasm and nucleus and microinjection of fluorescent proteins into cells. Individuals with experience in antibody and/or protein purification preferred. Salary range is \$15-17,000/year.

Please send résumé and 3 letters of reference to Dr J W Sanger, Department of Anatomy/G3, University of Pennsylvania, School of Medicine, Philadelphia, PA 19104. USA.

The University of Pennsylvania is an Equal Opportunity Employer. (NW158)A

# UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF

PHARMACOLOGICAL SCIENCE AND CLINICAL BIOCHEMISTRY RESEARCH ASSOCIATE

Applications are invited from candidates with an interest in metabolic biochemistry for a post-doctoral post of Research Associate to participate in a project on the toxicology of compounds which influence intermediary metabolism directed by Dr H S A Sherratt and Professor K G M M Alberti, which is supported by the Wellcome Trust. The post is available for two years from 1st February 1982. Starting salary £6,070 per annum on the Range 1A scale.

Applications, naming two referees, should be submitted as soon as possible to Dr H S A Sherratt, Department of Pharmacological Sciences, The Medical School, University of Newcastle upon Tyne, Queen Victoria Road, Newcastle upon Tyne NE1 7RU, from whom further information can be obtained, tel: 0632 328511 ext 3031. (058)A

# THE TECHNICAL UNIVERSITY OF DENMARK ASSISTANT/ASSOCIATE PROFESSOR "APPLIED MICROBIAL GENETICS"

At the Department of Microbiology a position as assistant/associate professor is to be filled from the 1st of May, 1982 or later. The successful candidate will assist in the establishing of a new group in "Applied Microbial Genetics". The group will be responsible for teaching and research within this field (recombinant DNA technology, host-vector systems, optimalization of gene expression, genetics of industrial microorganisms, risk assessment, etc.). Applicants with experience in molecular biology, genetics and biochemistry, preferably with industrial microorganisms, will be given preference.

The applicant should be able to develop independent research projects and is expected to cooperate with existing research teams. Furthermore, the applicant should have an appreciation of the social implications of this field in accordance with the report having formed the basis of the establishment of this field. This report may be obtained from the Secretariat of the Faculty (telephone 452-882222 ext 2237).

Further information may be obtained from Professor Kaspar von Meyenburg, Department of Microbiology, Building 221, Technical University of Denmark, 2800 Lyngby (telephone 452-884066 ext

The salary is fixed according to the agreement between the Ministry of Finance and the relevant trade union. Details on the mode of employment especially with regard to the first year may be obtained from the Secretariat of the Faculty.

The application should include curriculum vitae, relevant publications, if possible in 3 copies, and a detailed account of teaching experience.

The application is to be addressed to: The Faculty Council of Chemical Sciences, Technical University of Denmark, Building 101A, 2800 Lyngby, Denmark.

The application should be to hand for the University not later than the 5th of February, 1982. (W536)A

# THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments are usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

# UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF CLINICAL BIOCHEMISTRY AND METABOLIC MEDICINE

# RESEARCH ASSOCIATE (BIOCHEMIST)

Applications are invited for a temporary post-doctoral biochemist Research Associate in the above department. The successful candidate will work closely with the Head of Department in a research group supported by the British Diabetic Association investigating the effects of experimental diabetes and its treatment on intermediary metabolism. Experience in intermediary metabolism, enzymology, enzyme activation, pancreas transplantation or mechanisms of hormone action would be advantageous. The appointment is available from 1st February, 1982 and will be for three years. Salary on the Range IA scale £6,070 — £10,575 per annum.

Applications, giving full curriculum vitae and two referees, should be submitted within two weeks of the appearance of this advertisement to Professor K G M M Alberti, Department of Clinical Biochemistry and Metabolic Medicine, Royal Victoria Infirmary, Queen Victoria Road, Newcastle upon Tyne, from whom further information can be obtained (tel: 0632 328511 extension 3132).

(059)A

# HILL FARMING RESEARCH ORGANISATION

# Scientific Officer

Applications are invited to fill a Scientific Officer vacancy at our Sourhope Research Station. The station is situated approximately seven miles from Yetholm in Roxburghshire.

The successful appointee will assume overall responsibility for and provide assistance with collection and submission of all experimental data to Headquarters. They will also have some responsibility for the collection and transmission of data from non-routine experimental work, act as deputy when the Officer in Charge is absent from the Station and assist or accept sole responsibility for looking after parties of visitors to the Station.

Qualifications: HNC or HND or a pass degree or equivalent in a scientific or mathematical subject. Preference will be given to candidates with a qualification in agriculture.

Salary: Depending on qualifications within the range £5,176 to £6,964 with £5,718 being the maximum starting salary.

Other conditions: Non-contributory superannuation scheme 20 days

annual leave. Under normal conditions 5 day week (42 hrs)

Application forms and further information may be obtained from the Secretary, Hill Farming Research Organisation, Bush Estate, Penicuik, Midlothian EH26 0PY to whom they should be returned not later than 8th January 1981. Please quote ref A/6/265

# STRANGEWAYS RESEARCH **LABORATORY ENVIRONMENTAL CARCINOGENS GROUP** POST-DOCTORAL RESEARCH ASSISTANT

A Biologist with research experience in histo-pathology is required to work on carcinogenesis induced by industrial and environmental particulates. The programme is especially concerned with possible synergistic processes between mineral and metallic particles and fibres, and systemic carcinogens, all at low level.

The project is funded by the Health & Safety Executive, and the appointment will be for a 3 year period. It will be made in the MRC Non-clinical Scientific Grade II range with USS benefits at a Salary level depending on age and experience.

Curriculum vitae with 2 referees to: Administrative Secretary, Strangeways Research Laboratory, Worts Causeway, Cambridge CB1 4RN.

# UNIVERSITY OF LONDON **British Postgraduate** Medical Federation

CARDIOTHORACIC INSTITUTE DEPARTMENT OF ALLERGY AND CLINICAL IMMUNOLOGY

# MEDICAL LABORATORY SCIENTIFIC OFFICER

Applications are invited for the above position available for at least two years. The successful candidate will be involved in a research programme on the role of leucocytes in inflammatory and allergic responses in both humans and laboratory animals. Experience in biochemical/ immunological/parasitological techniques is desirable, and applicants should hold a relevant HNC or equivalent.

Application forms are available Application forms are avalable from The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP. (Tel: 01-352 8121 ext 4163). Closing Date 15th January

# **ICHTHYOLOGY JOB** DESCRIPTION

Cornell University solicits applications for a tenure-track position, preferably an Assistant Professor, in the Section of Ecology & Systematics to begin September 1982. We seek a Systematic Ichthyologist with broad interests in vertebrate biology and a strong research program. The successful candidate will participate in curation of the Ichthyology Collection. Teaching responsibilities include an upper-level course, and participain the graduate program in vertebrate biology.

Applications must include a curri-culum vitae, names of three references, and will be reviewed February 1, 1982. Send application to: Dr W N McFarland, Section of Ecology and Systematics, Cornell University, Ithaca, New York 14850. Cornell University is an affirmative action/equal opportunity employer. (NW157)A

# UNIVERSITY OF ARIZONA DEPARTMENT OF CHEMISTRY **ACADEMIC POSITION**

Invites applications for a possible tenure-track position at the Assistant Professor level in one of the following areas: (1) Synthetic Solid State Chemistry; (2) Surface Chemistry; and (3) Atmospheric or Low-Temperature Geochemistry.

Candidates should have demonstrated in their Ph D and/or postdoctoral work the ability to develop a vigorous and innovative research program in one or more of the above areas and have a commitment to instructional excellence.

A résumé brief description of research plans, and three letters of recommendation should be sent to Professor William S Glaunsinger, Chairman, Search Committee, Department of Chemistry, Arizona State University, Tempe, Arizona 85287. EO/AA employer. (NW146)A

# THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S **HOSPITAL**

(University of London) West Smithfield, London EC1A 7BE

# POST DOCTORAL RESEARCH FELLOW

required in Department of Haematology for Cancer Research Campaign grant entitled "Isolation and Characterisation of regulatory variants for the expression of murine lymphocyte cell surface antigens". Experience in cell membrane biochemistry necessary and immuno-logy/cell culture experience desirable. The post is tenable for three years from 1 January 1982, or soon after. Salary on Scale £6,070 — £10,575 plus

Apply in writing with CV and names of two referees to The Secretary of the College at the above address, quoting ref 925. Further information from Dr M A Horton Tel: 01-600 9000 extension 3272. (021)A

# Southampton THE WINIVERSITY

# **INSTITUTE OF CRYOGENICS**

Applications are invited for the following appointments in the Industrial Advisory Unit:

### 1. Technical and **Projects Manager** 2. Research Scientist or Engineer

Candidates should be graduates in Science or Engineering and have working research experience in industry in either cryogenics or refrigeration engineering.

The Unit is an integral part of the Institute of Cryogenics and some teaching ability is required.

Salaries in range to £12,860 depending on qualifications and experience.

Experience.
Further particulars from D. A. S.
Copland, The University, South-ampton SO9 5NH, quoting reference no 319/A/N. (070)A

# LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

# FIELD PROJECT IN MALAWI ASSISTANT TO DIRECTOR

Required to work on a contract of not less than 3 years' duration for the Director of a long-term Leprosy Evaluation Project in Northern Malawi. The primary responsibility is in relation to quality control of data but some field work may be involved. Experience in Epidemiology, Statistics, management of social survey data or another relevant area is required. Candidates must be mature and be fully fit to serve in the tropics in rural conditions.

A salary of not less than £6,000 is envisaged together with free passages for the successful candidate (and spouse, if married). Tropical kit and overseas allowances are paid.

Applications, consisting of full curriculum vitae and the names and addresses of two referees, should be submitted to Dr P E M Fine, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, from whom further articulars may be obtained. (066)A

# UNIVERSITY OF DUNDEE

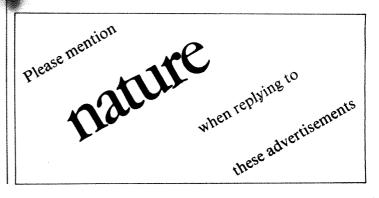

DEPARTMENT OF PHYSICS

### There are two vacancies for RESEARCH ASSISTANTS

to work for up to three years as members of a research group directed by Professor W E Spear, FRS and concerned with the development of amorphous silicon devices. The posts offer challenging opportunities to applicants with higher degree or professional qualifications in physics or electrical engineering and with some relevant research or development experience preferably in the amorphous semi-conductor field.

The starting salary for both posts will be in the range £5,285 — £6,880 per annum.

Applications containing full curri-culum vitae (3 copies) and the names of two referees should be sent by 7th January 1982 to the Personnel Office, The University, Dundee, DD1 4HN. Please quote reference EST/58/81J. (069)A

# AGRICULTURAL RESEARCH COUNCIL Poultry Research Centre, Roslin, Midlothian EH25 9PS **Poultry Scientist (Breeder Production)** HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

A Poultry Scientist (Breeder Production) is required to carry out applied research aimed at improving the productivity of breeding chickens and research aimed at improving the productivity of breeding chickens and turkeys. Initially, emphasis will be given to nutritional research but cooperation with other scientists in the Centre, to apply findings from different areas of basic science, such as Reproductive Physiology and Ethology, is expected. The appointee will be required to liaise with advisory and industry groups to ensure effective innovation in this programme and application of the findings.

Training in agricultural science, research experience and a demonstrable interest in applying scientific work to animal production are required. Computer modelling and other quantative methods are important in this

field and candidates should have relevant skills and/or interests.

Qualifications: First or upper second class honours degree in Agriculture, Agricultural Science, Applied Biology or related subject, with at least 2 years post-graduate experience; 4 years postgraduate experience is necessary for entry at Senior Scientific Officer level. A postgraduate qualification would be preferred.

Salary: In scale £6,530 — £8,589 at HSO level, £8,209 — £10,322 at SSO level. Non-contributory pension scheme. 22 days annual leave.

Applications forms are available from Mr. A. I. Menzies, Institute Secretary, at the above address. Completed forms must be (084)A returned to him by the 8th January 1982.

# UNIVERSITY OF BATH

DEPARTMENT OF PLANT BIOLOGY

# POSTDOCTORAL RESEARCH OFFICER

required for project on the freezepreservation of potato germplasm, supported by the Overseas Development Administration and directed by Professor G G Henshaw. Experience of tissue culture and/or cryobiological techniques would be an advantage.

Starting salary up to £6,880 according to qualifications and experience. Ref no 81/128.

# **EXPERIMENTAL OFFICER**

required immediately for above research project and associated work with potato tissue cultures. Applicants should have some experience of tissue culture or aseptic techniques and be qualified to at least HNC or equivalent.

Starting salary up to £5,762 according to qualifications and experience. Ref no 81/129.

Application forms and further details from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting the appropriate ref Closing date: 4.1.82. (072 (072)A

# ISTITUTO NAZIONALE DI FISICA NUCLEARE (INFN)

# **NUCLEAR AND PARTICLE PHYSICISTS**

Applications are invited for two research posts for one year, starting October 1982.

The first post is for a theorist working in intermediate energy nuclear physics, either at the Istituto di Fisica, Università di Genova, or at the Istituto di Fisica, Università di Cagliari.

The second is for a theorist working in elementary particle physics, with a specific interest in field theory and fundamental interactions.

Both positions are for non Italian citizens and are at a senior level.

Salary will be determined by the individual experience and present position of the applicant.

Send applications and requests for further information to: Prof Dr Antonino Zichichi, Presidente, National Institute of Nuclear Physics (INFN) Piazza dei Caprettari, 70 00186 Rome - Italy.

The application deadline is February 15, 1982. (W540)A

# **INVERTEBRATE PHYSIOLOGIST**

The Department of Biology of the Pennsylvania State University invites applications for a tenure-track position for an invertebrate physiologist to begin Fall 1982. A PhD degree is required. Preference will be given to applicants who interface strongly with ecological and evolutionary aspects of invertebrate physiology and who will interact with present faculty in the department. The successful candidate will be expected to develop a strong research program and teach an introductory undergraduate course and an upper division or graduate course in his/her area of expertise. Rank depends on qualifications and experience. Submit curriculum vitae, statement of research and teaching interests and three letters of recommendation by 15 February Invertebrate Physiologist, Search Committee, Department of Biology, 208 Mueller Laboratory, Box 4, Pennsylvania State University, 208 Mueller Laboratory, University Park, PA 16802.

An Equal Opportunity/Affirmative Action Employer.

(NW162)A

# CHAIR **DEPARTMENT OF** ANATOMY & CELL BIOLOGY DOWNSTATE MEDICAL CENTER

Candidates and those wishing to nominate candidates are asked send a curriculum vitae to Dr Bernard Jaffe, Chairman, Search Committee, Downstate Medical Center, Box 40, 450 Clarkson Avenue, Brooklyn, NY 11203.

# EMBO SENIOR FELLOWSHIPS

During 1982 the European Molecular Biology Organization will award a limited number of Senior Fellowships to exceptionally qualified molecular biologists from Europe and overseas wishing to spend a period of 6 or more months in laboratories in the countries listed below. These fellowships cannot however be awarded for exchanges between laboratories in the same country. To be eligible to compete for these fellowships a candidate must have at least 8 years post-doctoral research experience and have made distinguished contributions to molecular biology or related fields of science.

The fellowships will comprise a travel grant (tourist class air fare) for the fellow and his dependants and an appropriate stipend. Although initially awarded for not less than 6 months and no more than 12 months, the fellowships may, subject to review by the EMBO Fund Committee, be renewed for a further period.

Further information concerning the fellowships and stipends as well as application forms may be obtained from Dr. John Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 6900 Heidelberg, Federal Republic of Germany.

Completed applications recieved before February 19, 1982 will be reviewed by the Fund Committee on April 30, 1982 and any awards made can be activated immediately.

The Host laboratory must be one of the following countries; Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom. (W534)E

# IMPERIAL COLLEGE DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE POST-DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a threeyear post-doctoral fellowship to study the role of chemical additives to alleviate slagging in coal-fired boilers. The project is supported by the SERC and Babcock Pwer Ltd under the co-operative award scheme.

The aim of the investigation is to eludicate the role played by trace quantities of transition metal compounds in alleviating the slagging and thus improving the thermal efficiency of coal-fired boilers.

Applicants should have a first degree in chemistry, physics or an applied science. Industrial experience in coal combustion or research experience in the fields of electron microscopy, X-ray diffraction or high-temperature chemistry is desirable though not essential.

Salary according to age and experience, is on the scale £6,880 — £7,700, plus London Allowance of £967.

Applications, including the names of two referees, should be sent to Dr J Williamson, Department of Metallurgy and Materials Science, Imperial College, London SW7 2BP, by 2nd January, 1982. (056)E

# ISTITUTO NAZIONALE DI FISICA NUCLEARE (INFN) TWO POST-DOCTORAL FELLOWSHIPS IN THEORETICAL NUCLEAR AND PARTICLE PHYSICS

For one year, starting September 1982, for non Italian citizens. The chosen applicants can pursue their research at any of the following Laboratories and Sections of INFN:

National Laboratories of Frascati (Rome); National Laboratories of Leganro (Padua); National Southern Laboratory (Catania); INFN Section of Turin; INFN Section of Milan; INFN Section of Milan; INFN Section of Padua; INFN Section of Trieste; INFN Section of Bologna; INFN Section of Florence; INFN Section of Pisa; INFN Section of Rome; INFN Section of Rome; INFN Section of Pisa; INFN Section of Catania; INFN Section of Catania; INFN Section of Sanità (Rome).

The salary will be approximately 800 US dolars per month for twelve months.

Send applications and requests for further information to: Prof Dr Antonino Zichichi, Presidente, National Institute of Nuclear Physics (INFN) Piazza dei Caprettari, 70 00186 Rome — Italy.

The application deadline is February 15, 1982. (W539)E

# LINCOLN COLLEGE, Oxford

# EPA CEPHALOSPORIN JUNIOR RESEARCH FELLOWSHIP IN MEDICAL, BIOLOGICAL OR CHEMICAL SCIENCES

The College invites applications from graduates, of either sex, under 28 years of age on 1st October, 1982, for a Junior Research Fellowship in Medical, Biological or Chemical Sciences, tenable for three years from October, 1982; applications from older candidates will be entertained in special circumstances only.

Further particulars may be obtained from the Rector, Lincoln College, Oxford OX1 3DR, to whom applications should be submitted by 14th January, 1982. (013)E

# UNIVERSITY OF DUNDEE DEPARTMENT OF BIOCHEMISTRY

Applications are invited from Honours Graduates in Biochemistry for a RESEARCH ASSISTANTSHIP

funded for 3 years by the MRC. The successful applicant will work with Dr D A Stansfield on an investigation of the guanine-nucleotide regulation of LCG-sensitive luteal adenylate cyclase. Further details of the post are available from Dr Stansfield at the Department of Biochemistry, the University, Dundee.

Applications (3 copies) naming 2 referees should be sent as soon as possible to Mr K M Cocker, The University, Dundee DD1 4HN. Please quote Ref: EST/61/81J.

(073)P

### CONFERENCES and COURSES

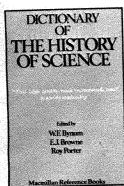

# EMBO COURSE IN ELECTRON MICROSCOPE IMAGE ANALYSIS European Molecular Biology Laboratory

The course, to be held from April 21st \_ 28th, 1982, is aimed at students who already have some background in biological electron microscopy or structural studies and who wish to learn the available techniques of computer image analysis. The following topics will be covered.

Methods for reducing specimen damage. 3-D reconstruction of periodic objects. Correlation methods for averaging.

Applicants should write to the organisers before 15th February 1982, giving the relevant details of their scientific background and their reasons for wishing to attend. No fee will be charged but the number of students will be limited to 20. Organisers: K. R. Leonard, J. Dubochet and T. Pitt.

EMBL, Postfach 10.2209, 69 Heidelberg, Germany. (W535)C

# Is Save & Subscribers to Nature This Save & South Special offer to Subscribers to Nature This Save & Subscribers to Nature This Sav

# the missing link?

Is there a gap in your bookcase? Until now, there hasn't been a dictionary devoted exclusively to the history of scientific ideas. And however you are involved in today's scientific world, you will agree that your present work and scientific attitudes are inevitably influenced by and built on those from the past.

Science and its key doctrines – from quantum theory to genetics – are central to the modern world; yet daily it changes and develops, becomes more technical and diverse. What is needed is a reference book that enables you not only to master the past but also to keep you in touch with the theories underlying the most recent scientific and technological developments.

The Dictionary of the History of Science fills the gap.

# Authoritative

It is the work of three editors: W.F. Bynum, E.J. Browne and Roy Porter; of ten subject editors – including Michael Hoskin, Richard Burkhardt, William Brock, Steven Shapin, Roger Smith, Eric Aiton, Roy Bhaskar, John Heilbron – and over 90 contributors, all authorities in their field. It explains the core features of Western science and their development. 700 entries, alphabetically arranged, cover such fields as astronomy, biology, chemistry and earth sciences, the historiography, philosophy and sociology of science; human sciences, mathematics, medicine and physics.

Substantial concepts such as Evolution and Light are given generous entries, while more specialized subareas like Neo-Darwinism and Light Velocity are allocated smaller amounts of space. All are cross-referenced back and forth.

# Comprehensive

Although the Dictionary is principally concerned with the Western scientific tradition of the last 500 years, it touches, too, on the central scientific ideas of classical and medieval times, and of other cultures. In addition, it features such topics as the development of technology and clinical medicine, and of important scientific instruments like the astrolabe and the thermometer.

Our understanding of the processes of scientific discovery and change is often controversial. But however you view them, it is important that you have easy access to all the ideas you are building on today, in the most scholarly, up-to-date and comprehensive detail.

If you are searching for the missing link, the Dictionary of the History of Science is your natural selection. At this special price to subscribers to Nature, it must be!

Price: £14 (Published price: £17.50)

2:00 Lunch with Lydia tons!

3:30 hydrolyze 8:30 sequence
3:30 hydrolyze 8:30 sequence

The primer primer primer as a sequence as

At the push of a button, in your own lab, you can produce sequences of DNA with BIO LOGICALS' fully automated DNA/RNA Synthesizer. You can synthesize sequences of up to 20 bases in length in less than 10 hours. No longer will your experiments be limited by the availability of probes, primers, promoters and other sequences.

Everything you need to produce oligonucleotides is available in one package. All bases and reagents are prepared and prepacked. You simply connect two manifolds to the instrument, program your sequence and the DNA/RNA Synthesizer makes it automatically without error.

You have heard and read about the new 'gene machines'. The only fully automated DNA/RNA Synthesizer is available now from BIO LOGICALS. Our instrument employs proprietary state-of-the-art phosphite triester chemistry.

Our DNA/RNA Synthesizer is reliable. To back that up: if your instrument is down during its one year warranty period we will deliver sequences to you for just the price of the reagents.

SAME DAY DNA!™

### Aims and Scope

Human Neurobiology is primarily devoted to studies of the biological basis of mental activity and human behavior. Though the major emphasis is on the species of man, it also publishes investigations on other primates related to human neurobiology.

Human Neurobiology attempts to cover and integrate neuropsychology, sensory physiology, neuroendocrinology, neurology, neurosurgery, neurophysiology, neuropsychiatry, neurolinguistics, neuroethology, developmental neurobiology, neurochemistry, neuropharmacology, neuroanatomy, and neuropathology.

It will thus form a bridge between basic and applied science within the fields mentioned. Human Neurobiology publishes issues containing independent original articles as well as reviews. Some issues are devoted to special topics.

# **INBRED STRAINS IN BIOMEDICAL** RESEARCH

MICHAEL F. W. FESTING

Geneticist at the Medical Research Council's Laboratory Animals Centre, Carshalton.

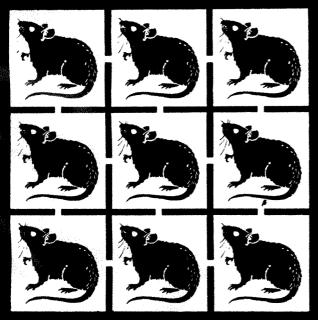

£25; 495pp; ISBN 0 333 23809 5

"This is an important work that should be on the shelves of every laboratory carrying out research with vertebrates." Laboratory Animals, January 1980.

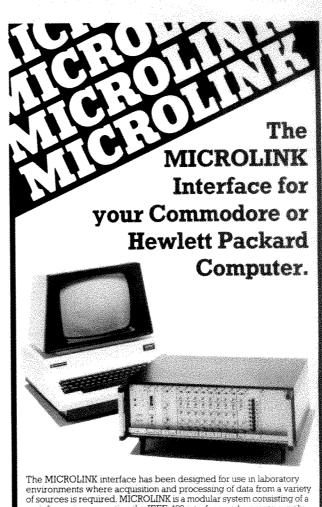

Inbred strains of mice, rats and guinea pigs have been available for well over half a century and they have made a substantial contribution to many areas of biomedical research.

In spite of these major contributions, particularly in cancer research, there are still many areas of biomedical research in which inbred strains are hardly used at all, and even when they are used their properties are not fully understood. This is the first book to be devoted exclusively to inbred strains and their properties - over 400 are listed with details of their origin and known characteristics. This book will fill an important gap in laboratory animal literature and it is hoped that it will stimulate research workers in areas such as toxicology. biochemistry, parasitology and others, to consider ways in which inbred strains could improve the quality of their research.

For further details contact Frances Roach, Scientific and Medical Division Macmillan Publishers Ltd, Houndmills, Basingstoke, Hampshire.

# INTERNATIONAL DRTALITY STATISTIC

Michael Alderson, Professor of Epidemiology at the Institute of Cancer Research

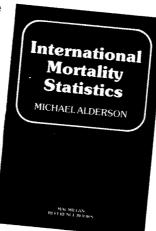

For the first time ever, 20th century mortality statistics are now available in a single volume, working with a common statistical base and a common set

405 pages of clearly laid-out tables present mortality statistics for 32 countries, 25 of them European. They are tabulated by sex, five-year periods from 1901 to 1975, 178 causes of death, and country.

Six introductory chapters give full explanations of the statistical method used, the validity of the data, and alignment of the international classification of diseases. This enables you to make your own evaluations and comparisons using the data, rather than providing a textual interpretation of the tables.

If you want to examine long-term mortality trends in one country, or to compare patterns in different countries, this book is your essential reference

The European countries examined are: Austria, Belgium, Bulgaria, Czechoslovakia, Denmark, England and Wales, Finland, France, Greece, Hungary, Iceland, Ireland, Italy, Luxembourg, Netherlands, Northern Ireland, Norway, Poland, Portugal, Romania, Scotland, Spain, Sweden, Switzerland and Yugoslavia. Outside Europe data are presented for the USA, Canada, Japan, Australia, New Zealand, Chile and Turkey.

# THE HAZARD FROM **DANGEROUS** EXOTIC DISEASES

John C. N. Westwood, Professor and Chairman of Microbiology and Immunology, University of Ottawa.

This book analyses the epidemic hazards of lethal and highly infectious exotic diseases to the very susceptible communities of the developed world

Professor John Westwood, one of the foremost authorities on infection control, assesses the nature and scale of the problem, and gives a detailed examination of six diseases which pose the greatest threat - Lassa, Marburg, Ebola and Yellow Fevers, Plague and Smallpox.

He outlines an appropriate level of response to ensure adequate control and containment, both in the community and in hospitals.

- ... a thoughtful and well-written book. As might be expected from a former director of virus research at the Microbiological Research Establishment at Porton Down, the description of the diseases and their causative agents is clear and accurate
- British Medical Journal
- ... most warmly recommended ... Westwood has made a valuable contribution

- The Lancet

# Poland, Christmas, Sakharov et al.

The scientific community cannot complain that some of its members live in states whose laws are illiberal, but should it acquiesce in the arbitrary loss of jobs?

The coincidence of recent events in Eastern Europe with the Christian celebration of the ancient festival of the winter solstice is not accidental. If, in Poland, the tide of social change that has occupied the past eighteen months is to be turned back by the threat of force, when better than this time of the year, when life is hard and food even more scarce than usual? But this is also the time when the despair of the despairing is heightened by the sense that winter's grasp has yet fully to close. This may help explain why a group of scientists in the Soviet Union has written to Nature to complain at their government's emigration policy (see page 688). Their letter is unlikely to make life easier for them, at least in the immediate future. The authors are nevertheless aware of what the consequences may be. That they have written their letter is a sign that they consider more conventional means of pressing their case have run into the sand. Will what they have to say be heard against the din of the forced jollity of the days ahead?

The authors of the letter appeal to the international scientific community, of which they wish to be a part. What response is appropriate? This question has much in common with those which have exercised scientific academies in the past several years. A few simple truths stand out. No part of the scientific community is competent to complain at the legal practices of individual governments, however illiberal or unjust. If, for example, it is still the practice somewhere to punish a thief by cutting off his right hand, that is no part of the scientific community's business. Similarly, scientists used to Western ways, and in particular to the knowledge that people's freedom to live and work elsewhere is constrained only by the willingness of host countries to receive them, have no right as scientists to complain that Soviet law gives the administration the right to withhold exit visas. It is true that the scientific community is impoverished - and the Soviet Union made to look foolish - when Soviet scientists are prevented from attending international conferences, but even that is not an occasion for public protest but a matter for diplomacy among the scientific academies (which, nevertheless, should be more energetic in this cause).

The disturbing feature of this week's letter from Moscow is that it suggests that individuals scientists in the Soviet Union may be victimized as scientists while acting within the law. It is common ground that to apply for an exit visa is not a crime. The fact that Dikii et al. are Jewish is (or should be) irrelevant, embarrassing though the flood of would-be emigrants to Israel has been for the Soviet government in the past decade. And their plight is by no means novel. Many Soviet citizens who have become in some sense awkward customers have found the loss of their jobs to be the first sign of having given offence and often a prelude to more serious trouble. Moreover, the loss of a job is not exclusively an accident befalling those who wish to go to Israel. There is at least one unpublished case of a graduate student who has been dismissed from the institute at which he was hoping to complete the work for his doctoral thesis on the heels of his application to join his wife in Western Europe. On the face of things, however, even this accumulating evidence of illiberality is not a sufficient cause for the scientific community to take up cudgels. If the convention is being established that those who legally fail to toe the conventional line will in the first instance lose their jobs, and if the sanction applies to all and sundry, surely the international scientific community has no special status in the matter? That is the

simplest (and most convenient) conclusion. It is, however, wrong.

First, it is more than probable that the convention that those who make trouble should lose their jobs will bear with especial severity on scientists in the Soviet Union. Continuity, as Dikii et al. proclaim, is crucial, especially early in a career; other kinds of professional people are usually (but not always) less vulnerable. Second, the importance (numerically and prestigiously) attached in the Soviet Union to professional work in science and technology is almost a guarantee that technical people will be prominent among the casualties of illiberality. Third, if scientists lose not only their jobs but access to scientific publication and are at the same time stripped of their degrees — a fanciful process in itself — the record of research is falsified. These are in themselves sufficient reasons why the scientific community elsewhere should take more than a passing interest in what is happening in the Soviet Union. But the most serious cause for alarm is the now well-understood procedure for arranging that those who figuratively blot their copybooks will then lose their jobs. Most Soviet laboratories have two directors, the better known of whom is a distinguished scientist. His partner is more directly concerned with political matters, including the hiring and firing of people. One of the unacceptable ironies of these arrangements is that the scientific heads of important institutions (who seem to have no difficulty with short-stay exit visas) are able to boast of the bright young people who work for them but to deny responsibility for those who have lost their jobs, to become dependent on the charity of friends and former colleagues. Such detachment (even if occasionally mirrored in the attitudes of the heads of laboratories in the West) is unfortunately not merely offensive but potentially destructive of the scientific enterprise. If bright young people are arbitrarily denied the chance to work the stint of which they are capable, and if the numbers are as substantial as those now accumulating in the Soviet Union, the enterprise will be undermined, not just impoverished. Those who enjoy the privilege of being directors of important Soviet institutes should be left in no doubt of how, by their indifference to or neglect of what is happening to the people in their charge, the consequence will be not merely to impoverish but to corrupt the scientific enterprise.

None of this will help Dikii et al. What should they do? Go on hunger-strike, like Andrei and Yelena Sakharov? For, contrary to expectations (see Nature 26 November, p.295) that ploy has worked. Dr Sakharov's putative daughter-in-law, Liza Alexeveva, has now joined his stepson in the United States. Mercifully, the Sakharovs are able to eat again (but they must please remember that they cannot keep on doing this, as they get older, with like impunity). Time will no doubt tell on what basis Liza Alexeyeva's departure from her homeland and the fasting Sakharovs was arranged. The Sakharovs probably compromised very little. But it is also plain that their despairing wager of their lives has been an uncharacteristically narrow venture. Their daughter-in-law has got away. The graduate student who impetuously married his legal wife is still stuck without a job somewhere in the Soviet Union. Should he ask his parents to go on hunger-strike? Both he and they, of course, know that that would carry relatively little weight. They may all think it a pity that the Sakharovs have spent their great influence on the solution of one person's problem when they might have been able to contribute to

0028-0836/81/520681-02\$01.00 ©1981 Macmillan Journals Ltd

a much more general resolution of a general important problem — even if one that is not directly the concern of the scientific community. That even brave people such as the Sakharovs might have been able to accomplish a step towards that goal is naturally a conjecture — and at times like the winter solstice, even people like them will be forgiven for putting Christmassy personal considerations before grand and perhaps unattainable causes.

None of this will much help the scientific academies or the individual members of the scientific community to know more clearly where they should stand on the events of the past few weeks. On the most immediate issues, they have no competence to make pronouncements of a scientific character even if they may choose to be vociferous in other roles. Precisely how the residue of what the Poles used to call Solidarity should be succoured is beyond their competence as scientists (although some, as scientists, may in future think differently of the problems of European defence). The only legitimate opening in this haunting argument for the scientific community is that represented by the hypocrisy of the institute directors from the East, who pretend that all the dreadful things that happen to those who used to be their young men and women are outside their competence. That defence can no longer wash - and it would be better for all concerned if the Soviet authorities would make (as would be their right) a simple rule that those who have benefited from the Soviet educational system must work their passage towards emigration by some system of indenture - so many years of public service for such and such a qualification would at least let people know where they stand, and would be consistent with the principle that sovereign states should be free to decide how to run their affairs. The growing practice of depriving skilled people as a kind of punishment of the right to practise their skills is a loss of more than a Soviet resource, and is offensive. Indeed, it is a disgrace.

# British academic agony

The British government has relaxed pressure on its universities, which may fail to take advantage.

The British government has now agreed to pay the second instalment of the cost of reorganizing and running down the British university system, decreed by the then Secretary of State for Education and Science just over a year ago. During the present academic year (which ends on 31 July 1982), the University Grants Committee has been able to set aside a total of £20 million to help with the cost of paying off redundant academics. In the following year, there will be a further £50 million to spend on measures of reorganization in the university system, but the government bravely says that it hopes not all of that will have to be spent on putting academics out to grass. If the Committee of Vice-Chancellors is to be taken at its first word on the subject (which would be imprudent), the settlement for next year will be totally inadequate to pension off university teachers whose tenure of their jobs cannot be sustained. In reality, of course, the crunch will come in the succeeding financial year, when the universities will have reduced their student numbers to those required of them by the University Grants Committee, and when their urgent need will be to trim their sails for the long haul that will by then seem to lie ahead. But the government has promised to provide a still unspecified amount of money to cover the costs of that year's mayhem; is it hoping that in the meantime (during 1982-83) the universities will have the wit to think of doing novel things, things they have not thought of yet?

The difficulty in understanding the conflict between the British government and the British university system is that it is not so much a conflict between an irresistible projectile and an immovable object as between blancmange and jelly (or jello). The government has discovered, late in the day, that the cost of firing tenured academics is not negligible, but dare not say so. The universities, on the other hand, are so frightened and affronted by what has happened to them in the past year, in particular by the discovery that they have fewer friends than students, that they

behave as if they have no choice but to pass on to their paymasters the information that they have gathered from the Association of University Teachers, the mild-mannered labour union capable nevertheless of making a lot of noise, that the cost of any change is bound to be greater than the cost of comfortable no-change. The time has come to ask whether even that seemingly prudent course can be wise.

Like the constituents of other university systems, British universities are naturally jealous of their autonomy. Their jealousy is, however, undimmed even while (as now) they are learning to live with instructions from the University Grants Committee that the numbers of students recruited in various fields should be determined in advance. The conventional statement of academic freedom is that self-governing universities should be free to decide for themselves who should teach what to whom. The difficulty, in present circumstances, is that the who is defined by the survivors now in post, that the what is largely determined by extension and that the to whom, the students, make their own numbers through the medium of the Universities Central Council on Admissions, falling so to speak where the academics lie. The new restrictions on student numbers rob the university system of a further degree of freedom, a loss which collectively the universities have not yet chosen to complain about. They should.

Individually if not collectively, they should also give some serious thought to what the more distant future holds. Although the government has been able to put some kind of limit on the cost of other kinds of higher education than those provided by universities, the lack of coherence between the universities and the polytechnics persists as a weakness of both systems. The universities, the more senior of the partners, should acknowledge that it is, in these hard times, for them to bridge the gap. While they are about it, they should also give more serious thought than has been their habit to the needs of their students and of their students' potential employers. British students are too highly specialized; British graduates are too uniformly academic. Not all but most universities should change their habits of selection and their ways of teaching so as to cater for a greater diversity of people and of interests. Over the past twenty years, British universities (singly and collectively) have resisted the notion that students are not all ideally the same, and that students' ambitions sometimes encompass secularly non-academic goals. That is obscurantist.

The plain truth about the distant future is that British universities are at present organized in such a way that they will all (except Oxbridge) sink together unless they have the courage to acknowledge that survival requires that they should exercise the autonomy of which they boast. Several corollaries arise. Academics should not always be paid the same, under "nationally negotiated agreements"; instead, universities should be free to pay their people what they can afford (and earn). Tenure should be limited, taking some account of the need to preserve people's freedom to write (and even to say) what they think fit, but acknowledging that universities cannot make lifelong contracts with their employees while living from hand to mouth themselves. The result of such an erosion of the common academic sense of security would send the better academics flocking to two contrasting kinds of places - secure universities valued for their sheer academic excellence and much more specialized places valued for their special skills at teaching students what much of the real world expects of them. The result, of course, would be more diversity among institutions of higher education. Would that necessarily be disastrous? The system as it is is calamitously

So how to get from here to there? The interpretation of the British government's budget restrictions by the University Grants Committee will, if unchanged, have an ossifying effect. Universities individually will preserve their present character but will shrink. Strange though it may seem, the universities probably find that dismal prospect preferable to the better alternative — a framework in which they would be enabled but also compelled to find for themselves a niche in the market in higher education.

# Balance of US energy research attacked

# Advisory group gives comfort to Reagan's foes

Washington

A top level advisory committee to the US Department of Energy (DoE) has told the Reagan Administration politely but firmly that it is not making the best use of its resources for energy research. In particular, the committee says that there is insufficient support for conservation technologies and that too much is being spent on nuclear energy.

The report was published shortly before President Reagan's announcement last week that he is soon to submit plans to Congress for dismantling DoE. He said that the purpose of the move is to create "a strong federal effort in basic research in energy that avoids excessive regulation".

The centrepiece of the reorganization is a new Energy Research and Technology Administration within the Department of Commerce. The plan is expected to meet fierce opposition in Congress, particularly from those who favour an independent energy research agency on the grounds that close links with the Commerce Department would reinforce the alleged pro-nuclear bias.

The criticisms of present energy research policies came from DoE's Energy Research Advisory Board (ERAB), an independent, non-partisan group. The chairman of the board is Mr Louis H. Roddis Jr, previously president of Consolidated Edison of New York, and the report was prepared at short notice at the request of DoE by a panel, led by Dr John S. Foster, vice-president for science and technology at TRW Inc., comprising all ERAB members and several outside consultants.

Objections to the Reagan plan are already coming from another direction, namely congressmen unhappy at the proposal that the nuclear weapons research carried out at the nation's weapons laboratories should be among the activities transferred to the Department of Commerce. Speaking at the National Press Club in Washington last week, commerce secretary S. Malcolm Balrige said that his department's experience with other research agencies, such as the National Oceanic and Atmospheric Administration, made it a natural place for locating energy research. He also admitted that the Commerce Department's responsibility to assist in increasing exports could logically include the international promotion of American nuclear technology.

The ERAB report takes as its frame of reference the policy guidelines laid down

by the Reagan Administration, thereby insulating itself from the criticism that it is making a political attack on Mr Reagan's policies. Although in principle enthusiastic about the new policy directions, the ERAB committee is concerned about how decisions, such as the cutting back of research funds for conservation and solar technology, have turned out in practice. And the report champions higher energy prices as the best way of encouraging efficient use of energy and utilization of new energy sources.

All 20 members of the committee agreed on the need to emphasize new energy technologies where research has already reached the stage at which the results could, if desired, be directly taken over by the private sector, and should otherwise be dropped if this desire does not exist. For example, the report recommends the elimination of support for research into small-scale hydropower and magnetohydrodynamics (decisions already made by the Reagan Administration), and a sharp reduction in support for research on electric vehicles.

Little change is advocated for most of

the basic sciences whose budgets are the current responsibility of the department, including high energy physics and nuclear physics, and which would be incorporated directly into the new agency. And the board favours greater support for efforts aimed at improving the quality and quantity of scientific personnel at US universities in energy-related areas, described as an area "appropriate for federal concern" but currently receiving only \$10.6 million a year.

The most controversial parts of the report are those which address directly the government's role in supporting research into the generation of electricity through nuclear power. The ERAB report describes the Clinch River fast breeder reactor as being "not an urgent priority", recommending that, under current budget constraints, such a demonstration project should be postponed. Four members of the advisory board, however, dissent from this opinion on the grounds that not proceeding with the construction phase of the fast reactor would mean writing off the \$1 billion that has been invested so far, and

# What case for building Clinch River?

Washington

Following Congress's decision last month to give the go-ahead for the construction of the liquid metal fast breeder reactor at Clinch River in Tennessee, the focus of the controversy surrounding the project has shifted back to the Nuclear Regulatory Commission (NRC), which would have to issue a permit allowing the construction to proceed.

Last week, the five members of the commission agreed to consider a request from the Department of Energy that it be given "emergency" exemption from conventional licensing procedures. According to Energy Secretary James Edwards, such an exemption is necessary to avoid the "undue hardship" which, he told NRC, would result from further hold-up in the long-delayed construction plans.

Critics of the reactor, however, claim that the Department of Energy is trying to manoeuvre NRC into providing a provisional construction licence as soon as possible so as to pre-empt further attempts by Congress to terminate the project. The critics claim that their case is substantiated by an internal Department of Energy memorandum, released last week by the Natural Resources Defense Council (NRDC), in which Under-Secretary of Energy Guy Fiske suggests that the request for an emergency exemption from NRC be withheld until the 1982 appropriation bill is passed - an amendment could

have been added forbidding the Department of Energy from making such a request — and that the Council on Environment Quality be asked about securing "strong support" for an internal environmental report establishing the "negligible environmental impact" of the construction of the reactor.

NRDC attorney Barbara Finamore said that the memo "reveals a calculated effort by the Department of Energy to undermine the integrity of the NRC and its licensing process". Supporters of the fast reactor, that the Clinch River project is needed to demonstrate this technology in the US licensing and safety environment.

Although the construction of the Clinch River reactor has been approved by Congress, its completion is not certain. It is generally accepted in Washington that the main reason for Congress's approval was political—the project is strongly backed by Tennessee Senator Howard Baker Jr, the leader of the Senate.

One possible outcome is that preliminary construction work will be carried out, partly to satisfy the pro-nuclear supporters in Congress to whom the fast reactor has become an important symbol, but that eventually even the utility companies which now back the project will agree that it is inappropriate to continue, and the Clinch River reactor will be abandoned on the grounds of its inefficiency and antiquity.

David Dickson

dissipate the "hard-won technology capability" already developed in the United States. The dissenters were ERAB chairman Louis Roddis, William S. Lee, president of Duke Power Company, Roland W. Schmitt, vice-president for corporate research at General Electric and John W. Simpson, a consultant previously with Westinghouse Electric. Described by critics as the "electric mafia" on ERAB, these same four are said to have been successful in toning down parts of the report which criticized the emphasis being given by the Reagan Administration to nuclear research as disproportionate to nuclear's role as an energy source.

The final report states merely that 'although no correct balance among energy forms and resources can be defined a priori, research and development for electric supply technology is receiving a larger proportion of funding than the present and projected share of electricity in our national energy supplies". In addition to recommending that the Clinch River fast reactor should not be built, the panel suggests that high priority be given to research into nuclear waste disposal and into conventional light-water reactors, and a "little less" funding into both breeder reactor fuel cycle research and magnetic fusion. **David Dickson** 

#### Data falsification

#### Harvard acts

Washington

Harvard Medical School announced last week that it was setting up a special committee of both faculty members and outside academics to recommend how the school should deal with future cases in which research workers are accused of producing falsified research data.

This announcement follows the resignation of a member of the medical school research staff, Dr John R. Darsee, who admitted that he had fabricated research data during an experiment last year which involved efforts to limit the damage caused by heart attacks in animals.

Dr Darsee also resigned his post as a research fellow at the Brigham and Women's Hospital in Boston. Before his resignation, according to reported comments from other members of the hospital staff, he had been under consideration to head a hospital laboratory.

As a result of allegations about Dr Darsee's work made last year by other research workers at the medical school, an investigation was carried out, in the course of which Dr Darsee admitted that he had falsified the research results in question.

A statement issued by the dean of the medical school, Dr Daniel C. Tosteson, last week stated that "none of the work which could not be verified has been presented to the scientific community". Earlier this year, Dr Darsee's supervisor, Dr Eugene Braunwald, decided that all

#### Christmas present for Heidelberg laboratory

The European Molecular Biology Laboratory at Heidelberg has half the Christmas present it was promised a few months ago: a liquid-helium temperature transmission electron microscope lens from Siemens AG, Munich, but not the pictures that should follow from it.

Dr Arthur Jones, head of the electron microscopy group at the laboratory, had hoped the system would have been operational by Christmas. But the lens — only the second commercial such lens in existence (the other went to Berlin) — arrived only a week ago. The first pictures, probably of hydrated crystalline specimens at 4 K, are likely to follow in January. Biological specimens should be in view in the spring.

Excitement is intense in the group about what they see as the most important development in electron microscopy for more than a decade. The Siemens group, headed by Dr I. Dietrich, appears to have shown that specimen damage by the electron beam — which limits the available resolution of a microscope on sensitive, nonperiodic biological specimens — may be reduced by orders of magnitude at 4 K.

And at the same time, Dr Jacques Dubochet, in charge of specimen preparation, claims now to produce hydrated biological specimens containing vitrified — non-crystalline — ice. (The formation of crystals would create artefacts and interfere with the imaging of specimens.)

At first, however, the resolution may be no better — or even worse — than with conventional electron microscopy, because the contrast available in hydrated specimens is much less than that possible with negative staining. The reduced beam damage, however, should compensate for this by allowing greater illumination, with the result that the microscope might reveal structures without the artefacts of the conventional stains. Ultimately the use of samples labelled with heavy atoms could make a greater, artefact-free resolution available says Dubochet.

After this "cryo-TEM" will come the scanning version, the "cryo-STEM". The first electron beam down the cryo-STEM is expected by mid-year, with the first images shortly after.

Robert Walgate

abstracts of Dr Darsee's work should be withheld from presentation at the annual meeting of the American Heart Association.

The National Institutes of Health (NIH) were also notified of the alleged falsification of data, since Dr Darsee was working on NIH-sponsored research and was in receipt of an NIH research fellowship, which he has since resigned together with his academic posts.

The advisory panel set up by Dean Tosteson is being chaired by Dr Richard Ross, dean of Johns Hopkins School of Medicine. According to last week's statement, the panel has been asked "to review the case in question, and to indicate whether or not any additional measures should be undertaken, and to recommend procedures for dealing with episodes of this kind in the future".

The committee has already started work, and its report is expected early in 1982.

**David Dickson** 

#### Molecular biology

# Limited progress

When the director-designate of the European Molecular Biology Laboratory (EMBL) in Heidelberg takes over from Sir John Kendrew in April, he will not find much room for movement in the budget. Last June, Sir John asked the ten-nation council for DM 32 million (£7.5 million) for 1982. In the event the council has now agreed to spend DM 30.2 million, roughly a 10 per cent increase on 1981 compared with a German inflation rate of about 6 per cent.

That allows for a small increase in staff this year — some 20–25 of whom 8–10 will be scientists, according to finance director Eckhart Weis. Thus the laboratory will edge ahead of local inflation, but will come nowhere near the "indicative scheme" prepared in 1980 which foresaw a budget increase of 20 per cent and a staff of 265 rather than the 220 now employed. The directorate, for "scientific reasons", did not fill the 265 posts which were available in 1980, and since then the recession has meant that the council would not agree to the budget which would be required to reoffer them.

Meanwhile, the new EMBL director, Professor Lennard Philipson of the University of Uppsala, refuses to define his policy for the laboratory until after he is in post. But he has been taking regular soundings, and, it seems, gaining everyone's confidence. He is said to recognize the important and unusual role that physicists play at the laboratory and the significance of the EMBL outstations at DESY, Hamburg (a synchrotron radiation source which has a long queue of applicants for beam time) and the Institut Laue Langevin, Grenoble (a neutron source).

It seems likely that the new regime will see a greater integration of the work at Heidelberg, and between Heidelberg and the outstations, with the selection of two or three principal areas of biology (cell membranes, for example) as broad foci of interest. But there will be nothing so blockbusting as an attack on the whole human chromosome — "that's factory work" said one senior EMBL scientist. On the

instrumentation side, certain techniques, such as gel electrophoresis, which are central to the new methods of molecular biology, may be singled out for increased attention; but Philipson is also said to have shown his support for the great efforts being made at Heidelberg to improve electron microscopy through cooling the microscope and specimen (see accompanying box).

At present Sir John Kendrew is still firmly in charge. He foresees an increase in the number of permanent scientific appointments (still less than a handful) at the laboratory in the next couple of years, as a batch of the early short-term contracts come to an end. Philipson, however, has made no commitments. As for Sir John himself, he feels that the seven years and three months for which he will have held the directorship is quite long enough.

Robert Walgate

#### Polish crisis

#### Science in limbo

The "state of war" proclaimed by General Jaruzelski's "Military Council for National Salvation" has brought all academic life in Poland to a standstill. The universities are closed as are several institutes of the academy of sciences. Scores of scientists and scholars have been arrested although some, such as the president of the academy, Dr Aleksander Gieyszter, have since been released. Others escaped arrest only by chance, being away from home when the police came, and are now in hiding. Solidarity organizers in the learned professions and activists from the Independent Students' Association have been interned. The Minister of Science, Higher Education and Technology, Dr Jerzy Nawrocki, is reported to have resigned.

This clamp-down on intellectuals is in sharp contrast with Jaruzelski's previous attitude. In a recent interview, Dr Leonard Sesnewski, one of the vice-presidents of the academy, said that Jaruzelski had always expressed warm feelings for scientists and that, on taking office as prime minister last February, he had immediately visited the academy to ask for their help in getting Poland out of its economic crisis.

Nevertheless, the growing drive for academic autonomy must have caused a certain friction between the general and the academy. At present, the academic secretary of the academy holds quasiministerial rank, and is responsible to the prime minister. In recent months, however, there has been considerable pressure from academy members and employees to incorporate into the proposed new bill on the academy clauses that would terminate this structure and make the academic secretary responsible only to his fellow-academicians. There has also been a drive - reflected in the Solidarity Congress resolution on learning and culture — to break down the barriers between the universities and the academy, so that academy employees could deliver lectures to undergraduates. This trend may have seemed dangerous to the authorities; a number of scholars, expelled or excluded from teaching posts for their political views over the past few years, have found a safe haven in academy research posts insulated from teaching.

For the time being, the concern of scholars abroad is focused on the plight of their Polish colleagues interned or in hiding. Professor Olof Tandberg and his colleagues from the Swedish Academy of Sciences (which traditionally has strong links with Poland) and several members of the Norwegian Academy have launched an appeal for financial support for the families of interned academics. Professor Tandberg has also received an appeal from a group of academy scholars in hiding asking for food, blankets and other essential supplies, including blood plasma. He has called on all other academies throughout the world to join the Norwegian and Swedish academics in this Vera Rich work.

#### UK agricultural research

# Endangered duo

Two British agricultural research institutes, the Long Ashton Research Station in Bristol and the Animal Breeding Research Organisation in Edinburgh, could be drastically cut or even closed if an economy proposal by the Agricultural Research Council is approved at its next meeting in February. Under threat are all research programmes at the Edinburgh institute except work on fundamental animal genetics, and the Pomology and Food and Beverages Division at Long Ashton.

The council (ARC) hopes the closures will save about £3 million in annual expenditure by 1983-84. (The budget for 1981-82 is £86 million.) According to Dr Ralph Riley, the secretary of ARC, the savings are needed both as a hedge against future government cuts and to allow greater flexibility in supporting research of high priority. The council's research programme has already suffered, he says, from a budget that has not kept up with inflation. Non-payroll expenditure has already been pared to the bone. But precisely how much of the £3 million saved will be available for starting new research projects after cuts in income are taken into account remains uncertain.

If the proposal is approved, the Long Ashton Research Station will be reduced to about one half of its present strength, with the loss of about 100 jobs. The Animal Breeding Research Organisation, however, will probably be closed and the research on animal genetics, which accounts for about one-fifth of the organization's activity, moved elsewhere.

ARC has made the proposal without

consulting the staff or directors of the institutes concerned, who first learnt of it only last week. The idea, according to Dr Riley, was for ARC to propose firm suggestions for savings and then to give those concerned two months in which to make a case before a final decision. The way in which the proposal was arrived at remains something of a mystery, but the main criterion seems to have been an assessment of priorities based on recent reviews of the work of all the council's institutes. Areas in which the council is likely to want to spend more money include fundamental genetics and biotechnology.

If approved, the proposal could have implications for the Ministry of Agriculture, Fisheries and Food, which spends about £44 million a year in ARC institutes on commissioned research. The ministry is optimistic that the work it commissions in the institutes under threat could be transferred to other institutes. Dr Riley, however, believes that this will be possible for most commissioned research but that there may be some areas where the ministry will have to look elsewhere. Judy Redfearn

#### High-energy physics

#### LEP marches on

The large electron-positron ring is on the move — in more than one sense. LEP will be the next big accelerator at CERN, the European Centre for Nuclear Physics, Geneva, and last week CERN member states finally agreed on the budget under which it will be built. Thus construction can begin as soon as local environmental approval is granted — by January or February, it is hoped. The second move is physical: LEP is to be built in a significantly new position, on a slope, which allows it to slide out of some tricky geological and political problems.

The budget agreed is sufficient, says CERN director-general Professor Herwig Schopper, to build LEP on the schedule foreseen a few months ago: fast enough to give colliding electron and positron beams of sufficiently high energy to provide physicists with copious neutral intermediate vector bosons by the end of 1987.

LEP is expected to cost SF910 million (about £263 million) at 1981 prices, with a further SF40 million (making a total of £275 million) for the first experiments. The money will be drawn from a guaranteed CERN annual budget of SF617 million.

The only major argument at the council was over what inflation index to apply to the 1981 budget to scale it up to 1982 prices. The usual CERN formula, appropriately weighted for CERN's Swiss salaries and expenditure abroad, gave 5.7 per cent. The council quibbled, and agreed on 4.4 per cent, losing CERN over £2 million next year.

The new slope for LEP (it was to have been horizontal) will be about 1.5 per cent from the Jura Mountains in the north west, towards Geneva. This enables the machine

to be slipped away from the cavernous Jura limestone, and further into the stable sandstone of the valley, in which all previous CERN accelerators have been built.

The result is that only 3 km (as opposed to 8 km previously) of the 27 km tunnel for LEP will be in the unpredictable limestone. Moreover, at the Jura side the ring will be higher — about 140 metres below the surface — so that if any difficult waterfilled caves are encountered, it will be possible to deal with them from above.

A further — and far from negligible — benefit may prove to be political. There has previously been vociferous environmental opposition to LEP from the French side (the Jura; LEP straddles the French-Swiss border). This opposition rested in large part on the (distributed) effect that the limestone borings might have on the source and flow of the River Allondon, which supplies water to a number of villages. The source was to have been within the LEP ring; now it is outside, and where the ring passes under the river it is within stable sandstone.

LEP will be paid for out of the current budget only by running down certain existing facilities. The intersecting storage rings for protons and other nuclei will be closed at the end of 1983; and operations on the 600-MeV synchrocyclotron (CERN's first accelerator) will be reduced to the mainly Scandinavian Isotope Separator On-Line (ISOLDE), which performs unique experiments on shortlived muclei and, incidentally, keeps the Nordic countries happy. Robert Walgate

#### UK university funding

# No reprieve

The British government is sticking to its guns over cuts in university grants, indicating that universities have failed to convince the government that spreading the cuts over five instead of three years would cost less because compulsory redundancies, involving large compensation payments, would be avoided. Last week, Sir Keith Joseph, Secretary of State for Education and Science, reaffirmed his belief that the cost to the taxpayer will be less if the cuts are implemented quickly.

Hence, it is no surprise that the universities' recurrent grant for 1981-82 has been set broadly in line with the government's expenditure plans of last April. The grant at £995 million will be only £16 million more than the estimate, to account mainly for an inflation rate higher than expected. The research councils, however, may have come off slightly better than feared. At £478 million, the science vote for 1982-83 will be roughly in line with this year's figure, although the allowance for increases during the year is only 5.5 per cent.

Despite his rejection of the universities' argument, Sir Keith has nevertheless accepted that the cost of redundancies

cannot be met out of the universities' recurrent grant. But his allocation of £50 million in 1982-83 for restructuring the university system has already met with derision from the Committee of Vice-Chancellors and Principals which says that the sum is far too small. The vice-chancellors also fear that if the 5.5 per cent inflation allowance cannot be met then the number of redundancies will increase. A sum for restructuring in 1983-84 will be announced some time next year.

Sir Keith expects to reach a decision early in the new year on the scheme proposed by the vice-chancellors' committee for compensating redundant academics. Academics who take their cases to court, however, could be awarded considerably more than indicated under the scheme, making it almost impossible at present to estimate the total redundancy bill.

Advanced higher education has fared worse than any other sector of education under the government's cutbacks. The overall reduction in the education budget next year compared with this is one per cent, with further education for non-academic school leavers winning increased support. Clearly, the universities have lost out to the much stronger voice of the growing numbers of unemployed.

#### Recombinant DNA research

# EEC safety dispute

Brussels

A deep division of opinion has become evident among the EEC's institutions over the need for strict legal controls to minimize the dangers of research using recombinant DNA techniques. By a narrow margin, the European Parliament's Committee on the Environment, Public Health and Consumer Protection came out against the EEC going than merely making recommendations on the registration of all relevant research. However, following a colloquy held in May (see Nature 21 May, p.181) the Economic and Social Committee (ESC) is strongly advocating that the European Community adopt a legally binding text enforcing tight safety controls.

Both opinions will be taken into acount by the ultimate decision-makers in the Committee of the Permanent Representatives to the EEC (Coreper) whose experts have been awaiting the views of the two consultative bodies.

The issue has been subject to an unusual amount of debate. In 1979 the European Commission itself proposed a legally binding directive along the lines demanded by ESC. This was then withdrawn and replaced by a set of recommendations to take account of evidence and scientific opinion which increasingly suggests that the dangers from bioengineering are less than were at first feared.

ESC thinks that the recommendations are too weak and that the reasons put forward to justify the original draft directive still hold good. It still considers that in the long term the unforeseeable and potentially serious consequences of recombinant DNA work require a "better safe than sorry approach", especially when pathogens are used as vectors or hosts. Also, the EEC has a responsibility to ensure that competition for commercially applicable research is not distorted by different rules on what can be done, and at what speed, in each member state.

The colloquy held by ESC to debate these points failed to budge the committee from its opinion, although many of the speakers there affirmed that the risks associated with genetic manipulation are small or negligible. The committee, however, remains convinced that transferring the techniques from laboratory to factory will not mean lower safety standards. Official guidelines would, therefore, be better than a system of self-regulation.

The report produced by Italian Euro-MP Domenico Ceravolo for the parliament echoes many of these concerns, but his resolution in favour of a directive was overturned in the committee vote by a majority of only one. In his report, Ceravolo attacks the European Commission's view by saying that even if a risk is only based on a hypothetical chain of events, this is no justification for thinking it any less valid or significant. And he argues further that the conjectural risks cannot be dismissed because no suitable criteria are available for assessing them.

Whether his arguments will win the day in the parliament's plenary session remains to be seen. A full vote was postponed at the last minute on 18 December but the vote is expected to go against Ceravolo. The liberals and conservatives, who form the majority in the house, support the Commission and feel that too much legislation will slow down the growth of Europe's biotechnology industry. The socialists and communists disagree and take their cue from the Italian left wing which sees EEC legislation as the best way of bringing Italian research under control.

Jasper Becker

#### Electronic publishing

# Journal plugs in

The British experiment to explore the feasibility of electronic scientific communication is well under way. The experimental electronic journal of the Universities of Loughborough and Birmingham, Computer-Human Factors, has received 16 papers in its first year — more than an earlier experiment in the United States received in its three-year life. Last week, the British Library, which is backing the experiment with £256,000, organized a demonstration for publishers,

journalists, editors and librarians.

The experiment is designed chiefly to identify the problems encountered by authors, editors, referees and readers in conducting editorial business on computers. Consideration will also be given to the possibility that electronic journals could fulfil the role of conventional journals. The experiment is also being used to investigate the role of computer networks for other less formal types of communication, such as newsletters, requests for comments on papers before submission to the journal, general communication between groups working on similar problems, the collaborative writing of papers and simply sending messages.

Members of the team working on the project say they are satisfied with the first year's results, ascribing their electronic journal's success in attracting papers to flexibility. In its purest form, an electronic journal would eliminate all paper; writing and editing would be done by means of VDUs (visual display units) and all transactions carried out over telecommunications links. Readers would also have access to the journal on their VDUs from a central computer memory.

Users of the journal preferring to see results on paper can get hard copy from printers at their terminals, and authors are also given flexibility by being allowed to submit papers either on-line or in the conventional way by posting typescripts to the editor. The editor can in-put perfect typescripts by optical character recognition but has to type in untidy ones on a word-processor. Of the 16 papers submitted so far, two have been on-line, and the rest came as typescript too untidy for optical character recognition.

The project, under editor Professor B. Shackel and his assistant Dr David Pullinger, is based at the University of Technology, Loughborough, and the central computer facility is provided by the University of Birmingham under the direction of Professor P. Jarratt. The 50 participants in the project, from universities throughout Britain, make up the journal's contributors and its only readers. Contributors are allowed to submit papers to conventional journals three months after submission to the electronic journal.

Although that option undermines the value of the electronic journal, its absence in the earlier United States experiment is thought to have dissuaded many potential contributors.

With two more years to run, the project is still at an early stage and the team is reluctant to draw many conclusions. Questions to be addressed, however, include the extent to which users can manage without paper, whether electronic journals could publish faster than conventional journals, the suitability of publishing papers and letters as soon as they are accepted rather than in batches as "issues" and alternative methods of refereeing.

Cost comparisons between electronic and conventional journals will be particularly difficult to assess. Capital cost could be minimized by using equipment initially acquired for other purposes, but running costs — chiefly the cost of using the telephone — will fall not only on the "publisher" but also heavily on users. One particular headache is how to compare the cost of reading time for conventional and electronic journals.

Even if this latest experiment demonstrates that electronic journals are feasible, the day when they become a practical reality in major subject areas is a long way off. The electronic journal, if it arrives, is likely to creep in gradually. Conventional journals, for example, may introduce new technology giving authors and readers the option of on-line access. But the problems of going entirely electronic are too formidable to be contemplated seriously for a few years yet.

#### Creation science trial

#### Verdict awaited

Washington

It may be another week before the verdict is known on the creationist trial which ended in Little Rock, Arkansas, last Thursday. Initially, Judge William Overton had promised an immediate verdict on whether a new state law requiring equal time for the teaching of evolution and "creation science" in state schools was unconstitutional.

At the end of the two-week trial, however, the judge announced that the amount of evidence presented was so large that his verdict would be delayed, although he has promised to deliver it by 31 December.

Despite the delay, the American Civil Liberties Union (ACLU), which brought the case on behalf of several local religious groups, biology teachers and school children, is confident that it has won. "It was no contest," Mr Bruce Ennis, the chief ACLU attorney, said after the trial had ended. "The state did what it could do. It was inadequate not because it did not do its job, but because creation science is a religion."

Supporters of creation science also

seemed to be accepting their defeat. But in this case the blame was being placed on the performance of state attorney general Steve Clark in defending the creation science law. The creationists promise a tougher fight in the next court case, which is likely to be a similar challenge against a creation science law passed in the state of Louisiana.

Although Judge Overton has yet to declare his verdict, he did say that it would be limited to the question of whether the creation science version of the origins of the world was religion, despite any explicit religious or biblical references in its description in the Arkansas law.

He added that he would not undertake to decide the validity of the biblical version of creation nor the theory of evolution. ACLU has asked the judge to determine various "findings of fact" — such as the definition of a scientific theory being based on natural laws and being "explanatory, testable and tentative" — which it hopes can be used in future court battles.

The second week of the trial was taken up largely by various witnesses called by the state to present a case in favour of creation science and the Arkansas bill, virtually identical copies of which are now pending before almost 20 other state legislatures.

Cross-examination by ACLU attorneys provided some colourful testimony. One supporter of creation science, having described how a creator could still be a scientific concept, perhaps comparable to Aristotle's "first cause", went on to describe his belief in exorcism and unidentified flying objects, claiming the latter to be attacks by Satan on God's world.

The star witness for the defence was Professor N.C. Wickramasinghe, head of the department of mathematics and astronomy at the University of Wales in Cardiff. Professor Wickramasinghe told the court that the odds against life originating by chance anywhere in the Universe were so high as to be virtually impossible. "One is driven almost inescapably to accept the possibility that life results from deliberate creation", he said.

He claimed that his own theories about the possible existence of microorganisms on comets bringing life to Earth had been rejected by other scientists largely because of their "indoctrination in Darwinism".

But if such statements were music to the ears of the creationists, there was less consolation when Professor Wickramasinghe was asked to comment on the creation science law, when he claimed that most of it was "claptrap", and that "certain parts of the law are demonstrably wrong".

One of the scientific witnesses who had been expected to appear for the defence unexpectedly left town shortly before he was due to testify. Another scientific witness whose appearance was cancelled by the state was Henry D. Voss, an electrical engineer who has published papers on space physics.

David Dickson

# CORRESPONDENCE

# Voices from a wilderness

Sir — We appeal for help to the editorial staff of *Nature*, to our colleague scientists and to the World Federation of Scientific Workers.

We are research workers of Jewish origin. More than two years ago, we came to the decision to leave the Soviet Union and accordingly applied for permission for our families to leave the country for Israel. Soviet law and present practices gave us reason to hope for a quick departure from the country since none of us has ever dealt with state or military secrets or with any questions connected with the security of the Soviet Union. Yet for more than two years we have been denied permission to leave, without reference to the Soviet legal code and without legal or lawful justification.

It seems that considerations in big politics do not take human lives into account.

We doubt whether our colleagues in the West realize what happens if a scientist in the Soviet Union declares his decision to leave the country. Almost all of us have lost our jobs and we are deprived of any possibility of continuing with our scientific research. The doors of scientific institutions, laboratories, seminars, conferences and symposia, editorial offices and publishing houses are shut in our faces. We are being deprived of our scientific degrees.

We feel that the danger of our creative death is becoming more and more real. Any scientist will understand what a two or three year break in scientific work means; and nobody can tell us how long our deprivation will last. Nobody is interested in our qualifications; nobody needs our work here.

Having lost our jobs, we find ourselves in a hard and humiliating financial position. We are anxious about the fate of our families; many of us have small children. We have in fact been thrown out of society, but at the same time we are not allowed to leave the Soviet Union.

All this has naturally had a harmful effect on our health — nervous depressions, hypertonic crises and other diseases have become our permanent companions. Our children are also affected.

We are in a situation where we can count only on the support and solidarity of our colleagues abroad, on their help and sympathy. Our voice in the Soviet Union is really a voice in the wilderness, our fate is of no interest to anybody and nobody answers

our complaints or petitions.

We understand that you all face important problems of your own, but hope that the fate of individual scientists — your colleagues — is also important and not a matter of indifference to you. For the world of science is common for everyone; it has common ethics and morals.

Indeed, our fate is closely connected with the attainment of lawfulness, the observance of the norms and rules of international pacts and human rights declarations, with the fulfilment of the Helsinki agreements and with adherence to humanitarian principles — with everything that makes possible mutual trust and mutual understanding between nations.

We are sure that struggle for the attainment of these principles is part and parcel of the struggle for peace and detente.

**SERC's plans** 

Sir — In your excellent leading article of 26 November (p.295) you state that the Science and Engineering Research Council "has just put off a plan to break new ground in the fashionable field of molecular electronics". It is certainly true that we are unable to fund in an adequate fashion programmes that certainly deserve support, but in the particular case of molecular electronics we are currently planning to increase our support of research in this potentially exciting area. Inevitably this means we have to cut back on other deserving areas.

B.W. OAKLEY

Science and Engineering Research Council, Swindon, UK

#### An acid test

Sir. — The objection of Darnbrough et al. (Nature 26 November, p.294) to data in our BioSystems paper on the origin of life is based, according to correspondence, on experiments with ATP at pH 11, where ATP is unstable. On page 162 of the article, which they cite inaccurately, experiments at pH 7.2 are described. This technical detail (that is, experiments at pH 7.2) is critical in judging their statements about plausibility. For readers interested in confirming this, the correct reference is Fox and Nakashima, BioSystems 12, 155–166; 1980.

SIDNEY W. FOX

University of Miami, Florida, USA

# Literary anarchy

Sir.— The problems raised in recent letters (7 May, p.7, 28 May, p.278) about literature search and by Dana L. Roth (8 October, p.422) about recruiting librarians with subject expertise may be solved if and when today's librarians turn towards Anarchism as in the following: "How to be an Anarchistic but Indispensable Librarian".—

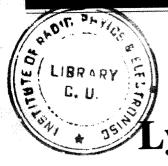

- Make your own rules so that you can change and interpret them according to circumstances.
- (2) Always act contrary to the rules
- (3) Use flexible opening hours; go out as often as possible so that your readers are happy if and when they see you.
- (4) Differentiate your catalogue cards.
- (5) a. Articles in authors' names may or may not be written after the names; sometimes split names are typed as whole ones.
  - b. Use alternatingly full and abbreviated journal titles; use different abbreviations for the same title.
  - c. Keywords are typed above the author's name or underlined; singular, plural, adjective and complex word forms are to be used.
  - d. Never use see- or see also-references.e. Never correct errors.
- (6) Foreign characters are alternatingly transliterated or not.
- Greek alphabet: transliterate or write in full (y = g or gamma).
- (6) 2. Figures are alphabeticized before or after plain characters but they may also be written in full in different languages.
- (6) III. Chemical substances will be found alternatingly under the common name, the scientific name, the product formula or the gross formula.
- (7) Print a catalogue of current journal titles but do not include the years or volume numbers your collections start with.
- (9) Move your books and journals regularly.
- (X) Take holidays without warning anybody; never tell the date of your return.
- (11) Never compose statistics with exact numbers but make rough estimates.
- (12) Avoid management techniques (whatever they may be).
- (13) Help your readers as well as possible; talk at least half an hour with every new customer and at least one hour a week with regular visitors.
- (14) Be fraternal: send now and then somebody on to other libraries
- (eight) Never write anything down but don't try to remember everything either.
- (Four) Make sufficient catalogues:
  monographs and reprints each have
  separated authors, journals and serials,
  systematic, and keywords catalogues;
  put all these catalogues in one piece of
  furniture.

If you do this and a lot of other things, you deserve the title "Anarchistic Librarian"; but: your customers will be satisfied and you have made yourself indispensable.

G. MERTENS (Anarchist) Librarian

Katholieke Universiteit, Leuven, Belgium

# NEWS AND VIEWS

# Lymphokines on the move

from Verner Paetkau

LEUKOCYTES which are stimulated with mitogens or strong antigens have long been known to secrete mediators with profound effects on other leukocytes. Non-immunoglobulin protein products with effector properties in the immune system have been designated 'lymphokines' and have a wide spectrum of activities. It is perhaps not surprising that, until recently, only a few immunologists were interested in these mixtures of soluble mediators — they were apparently antigen-nonspecific and poorly defined. How things can change! Today, the lymphokines and related soluble mediators command the serious attention of both theoretical and practical immunologists. Several lymphokines and their relevant cells have been characterized, and a picture is emerging of discrete molecular entities acting in defined (or definable) ways. In addition, the factor identified as interleukin-2 (IL2), which stimulates proliferation of T lymphocytes, is used to generate clonal sources of T lymphocytes with specific cytotoxic or helper activities. Today, the interleukins are a growth industry.

The present phase of work began in the mid 1970s and results from the convergence of several lines of enquiry. The sources of factors were normal leukocytes stimulated with mitogenic plant lectins such as concanavalin A (Con A) or phytohaemagglutinin. Not unexpectedly, the conditioned culture media used in early experiments contained a variety of activities, and different laboratories concentrated on different lymphokine assays. In one case, a soluble mediator greatly enhanced normal mitogenic responses of thymic lymphocytes to certain plant lectins. In another, lymphokine preparations generated from mitogenstimulated leukocytes were found to induce the continuous proliferation of functional T lymphocytes<sup>2,3</sup>. Similar preparations could also replace T lymphocytes in antibody-forming responses of B lymphocytes4, an activity referred to as 'T cell replacing factor' (TRF).

By 1978, it was evident that at least two molecular entities could be defined. One, a product of macrophages or monocytes, had been termed 'lymphocyte activating

factor'. The factor responsible for this activity has been renamed interleukin-1, and was recently purified to homogeneity<sup>5</sup>. The other, with effects on thymic lymphocytes, cytotoxic lymphocytes and T-depleted B lymphocytes, bore a number of designations, depending on the assay and laboratory. A single factor appeared to be responsible for this group of activities, there being no resolution by gel filtration, ion exchange chromatography, or isoelectric focusing. It was designated interleukin-2 (for T cell growth factor, thymocyte stimulating factor and costimulator). This was more than an exercise in semantics; it helped to focus the work and to give it some testable tenets. Because both biochemical and biological criteria for distinguishing IL2 and IL1 existed, it was possible to look for other activities in crude culture supernatants. Recent progress has been both stimulating and satisfying.

A soluble mediator which induces an enzyme activity (20-a corticosteroid dehydrogenase) associated with mature helper T lymphocytes has now been characterized by Hapel and co-workers6, and designated IL3. Conveniently, IL3 and IL2, which are both present in Con A-generated supernatants of normal spleen cell cultures, are separable by ion exchange chromatography. IL3, which is demonstrably free of IL2, interferon and TRF, stimulates the clonal outgrowth of T lymphocytes with surface antigens expected of T helper cells. Indeed, the clones eventually begin to generate their own IL3 and become able to grow independently of added factor. These putative T helper cells produce IL2 when stimulated with phorbol myristate acetate (PMA), an agent previously shown to elicit IL2 production from normal splenic T (helper) lymphocytes7. PMA apparently overrides the normal requirement for IL1 and antigen/mitogen for IL2 production8. Given the availability of biochemical separation methods and clonal cell lines for assay, one can soon expect a further

understanding of T cell signal networks, in which the roles of interferon, colony stimulating factor, IL1, I-A recognition, IL2, IL3, TRF and antigen will be identified more precisely.

The question of whether IL2 acts directly on B cells when it restores T cell function in antibody responses has not been answered definitively. The difficulties can be illustrated by recent work in which spleen cells of athymic mice were stimulated to grow by IL2 preparations, and in the process generated T lymphocytes (Lipsick and Kaplan, ref.9). This observation is consistent with previous results showing a recovery of T cell function in vitro and in vivo with IL2. The recovered T cell function may in turn be responsible for the restoration of T-dependent B cell function.

Does this report show, in contrast to what had been thought, that IL2 is directly mitogenic for T cells or their precursors in the absence of a second signal (antigen or mitogen)? The difference from earlier reports may be less significant than it seems. It is known, for example, that IL2 has no direct mitogenic effect at low cell density. In the Lipsick and Kaplan work. spleen cells were cultured at high density (5 million per ml) in serum-free medium; serum both enhanced background mitogenic activity and reduced that stimulated by IL2. A significant question remains — is the activity in fact due to IL2? Or, in light of the results of Hapel et al. 6, is IL3 at work? Although most of the experiments were performed with relatively crude IL2, which may well contain IL3, the same results were apparently obtained with preparations which should be free of IL3. Further direct evidence on this point will be welcome.

The question of direct effects of IL2 on B cells may be partly resolved by the finding that IL2 preparations contain a discrete factor which stimulates B cell proliferation<sup>10</sup>. Similar results are forthcoming from laboratories at the NIH (Bethesda) (M. Howard et al., personal communication). The B cell growth factor has been separated from IL2 (ref. 11). In the model studied, the NIH workers feel that IL2 is synergistic with B cell growth factor.

Verner Paetkau is Professor of Biochemistry in the University of Alberta, Edmonton, Canada.

Finally, what of TRF4? After many years of difficulty, created in part by the ability of factors like IL2 and the B cell growth factor to replace T cells indirectly, assays which clearly distinguish between IL2 and TRF are now in hand. And the take-home message is that, indeed, TRF exists<sup>12</sup>. It acts at the time when B cells, having undergone clonal expansion following antigenic stimulation, are to begin secreting high levels of immunoglobulin. Then, as proposed years ago by Dutton and colleagues, TRF can replace T cells in switching on a high level of immunoglobulin synthesis. Using spleen cells thoroughly depleted of T cells (this requires treatment of the donor animal with anti-thymocyte serum, in addition to the more common treatment with anti-Thy-1 antibody in vitro), Swain and coworkers have demonstrated synergy between IL2 and TRF in generating plaque-forming B cells. The role of IL2, although not yet delineated in this system, may be related to its ability to induce T cell

functions early (proliferative phase). The relationship to the newly described B cell growth factor awaits further experiments. In both cases, a clearer understanding of the roles of several lymphokines now exists, and perhaps more important, the tools and approaches necessary for more sophisticated analysis are evident.

An indication of future directions is

given by a current report describing a start on molecular biological studies of IL2. Given several T cell tumour lines which can be induced to generate high levels of IL2 (several thousand times the amounts produced by normal lymphocytes), it has been possible to follow the lead of workers in the interferon field, by looking for mRNA coding for the lymphokine, and then attempting to clone its complementary DNA. The EL4 variant cell line originally described by Farrar and colleagues at NIH<sup>13</sup> does indeed contain demonstrable IL2 mRNA. The poly  $(A)^+$ , 11-12S RNA derived from PMA-stimulated cells of this line, injected into Xenopus laevis oocytes, directs the synthesis of biologically active IL214. Similar results have been obtained by Gillis and colleagues in Seattle. The next phase of work clearly will involve molecular biological approaches. With venture capital panting for release, one may also expect that the term 'growth industry' could soon apply to lymphokinology in more than one way.

# A new view of supernova remnants in the Magellanic Clouds

from David Clark

FEW areas of astrophysics have not seen major changes following the highly successful Einstein X-ray observatory mission. The impact on the study of supernova remnants (SNRs) has been particularly impressive. When a massive star dies as a supernova, a shock wave is driven outwards from the site of the explosion, sweeping-up and heating interstellar gas to the millions of degrees required for thermal X-ray emission — so forming an extended X-ray remnant with characteristic peripheral brightening. Gas cooling behind the shock may be seen to radiate optically, and SNRs may also be detected at radio wavelengths. The radio emission is nonthermal, produced by fast electrons trapped in the interstellar magnetic field compressed by the expanding shock wave.

Because X-ray astronomy is a comparatively young science, pioneering surveys of SNRs in our own Milky Way, and its closest galactic neighbours, the Magellanic Clouds, were carried out in the radio and optical. Within the Galaxy more than 120 extended non-thermal radio objects were identified as SNRs. Detectable optical nebulosity was found only in the 30 closest of these because of the obscuring effect of dust permeating the plane of the Galaxy. A common characteristic of the optical remnants was recognized — the intensity of the red line emission associated with singly ionized sulphur with respect to the intensity of the red hydrogen Balmer line was very much greater in the shock-ionized plasma of SNRs than in photo-ionized nebulae. The combination of non-thermal radio emission and strong sulphur emission was taken to be a unique signature of SNRs,

and was used to detect remnants in the Magellanic Clouds and other nearby galaxies.

The pioneering survey of SNRs in the Magellanic Clouds by Mathewson and Clarke in Australia in 1973 used the radio/optical technique described above. The survey identified 14 remnants in the Large Magellanic Cloud (LMC) and 3 in the Small Magellanic Cloud (SMC), and was assumed to be almost complete (although a few other ring-like nebulosities seen in a deep optical survey of the Clouds by Davies and co-workers in 1976 were proposed as possible remnants). That assumption has been shattered by the X-ray survey of the LMC completed by Einstein and recently reported by Long, Helfand and Grabelsky (Astrophys J. 248, 925; 1981). Einstein detected X-ray emission from 13 of the known 14 LMC remnants, plus 12 other objects which are certain SNRs (5 of which were also in the Davies et al. list), plus 25 further objects which are possible SNRs on the basis of existing X-ray data.

The implications of these new discoveries are very significant. They seriously question the sole use in extragalactic SNR surveys of the traditional radio/optical SNR detection technique as it revealed perhaps just one-quarter of the LMC population of remnants. Optical nebulosity associated with many of the new remnants showed sometimes no sulphur emission - sometimes no hydrogen

David Clark is in the Space and Astrophysics Division at the Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire OX11 0QX.

emission. The new detections allow the supernova rate in the LMC to be lowered to perhaps one per century, contrasting with earlier estimates of one per 400-900 years. But most significant, the major population of LMC SNRs now identified in X rays and optically are found to be radio 'subluminous'; this result must call into question many of the studies of remnant evolution, distribution, ages, birth rates, distances and so on in our own Galaxy since such studies are based almost entirely on radio data. The new uniform LMC sample of SNRs should prove invaluble in future studies of remnant evolution at all wavelengths.

Observations of the six brightest LMC remnants using the solid-state spectrometer on Einstein are to be published shortly. These too show unexpected results. Four of the six display characteristic thermal spectra expected for shock-heated interstellar material; but the other two show non-thermal spectra suggestive of continued energy input. This is the case for the well known SNR the Crab Nebula, which in addition to emitting non-thermal X rays is brightest at its centre rather than peripherally, the emission being driven by an active pulsar. One of the LMC remnants, going by the rather unspectacular name of N157B, also shows unusual central brightening (as Australian radioastronomers showed several years ago) and mimics the Crab Nebula in other ways, including the non-thermal X-ray emission. It is the first Crab-like remnant detected in another galaxy, and must represent a prime site for the detection of the first extragalactic pulsar.

#### Are stress fibres contractile?

from Keith Burridge

Interest in stress fibres arises in part because their organization resembles the structure of striated muscle myofibrils. Not only do they contain many of the same proteins (for example, actin, myosin,  $\alpha$ -actinin and tropomyosin) but many of these are arranged in an alternating periodic pattern similar to that seen in sarcomeres. The similarity to muscle structure has suggested that they may have a similar function and be involved in non-muscle cell movement.

Here, however, is a paradox. Stress fibres are not required for cell movement or migration, and rapidly moving cells such as macrophages or amoebae lack them. Couchman and Rees1 have shown that fibroblasts migrating from primary tissue explants generally lack stress fibres in the first few days when they are migrating rapidly. With time the migration of the cells slows down and stress fibres become more prominent. The correlation of lack of movement with the presence of stress fibres has been best documented by Herman, Crisona and Pollard2. Fibroblasts migrating randomly in culture were filmed, then fixed and prepared for immunofluorescence with antibodies against actin, and examined for the presence or absence of stress fibres. Cells or regions of cells moving most actively appeared to contain no stress fibres while regions of cells with prominent stress fibres moved very little.

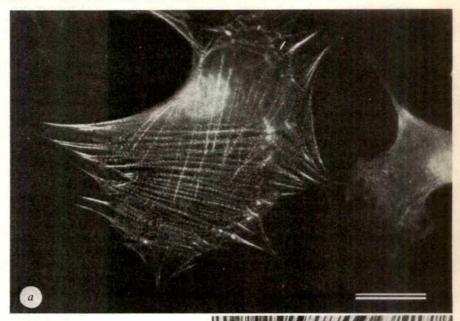

Because of the similarity of stress fibres to myofibrils, several groups have looked for contractility. Isenberg and co-workers3 demonstrated that stress fibres which have been microdissected from living cells with lasers will contract in the presence of Mg2+-ATP. An elegant approach was used by Kreis and Birchmeier4 who microinjected fluorescently labelled α-actinin into living cells so that it would be incorporated into the stress fibres. Contraction was then induced in permeabilized cell models with Mg2+-ATP. During such contractions, shortening of the non-fluorescent space between the fluorescent regions of a-actinin was observed, consistent with a sliding filament mechanism like that found in muscle. Contraction was not, however, observed in live cells as they first had to be permeabilized. Clearly these structures are potentially contractile, but what is their function in intact cells?

It would be helpful to know under what physiological circumstances stress fibres are found in the body but, unfortunately, rather little information is available. Stress fibres have been described in aortic endothelial cells of hypertensive animals5 and also in the granulation tissue of wounds6 but fibroblasts in many normal tissues do not contain prominent stress fibres. Growth of fibroblasts in culture seems to promote the development of stress fibres, perhaps reflecting unphysiological conditions of the culture environment. Unlike conditions in vivo, cultured cells grow on a rigid substrate to which normal fibroblasts adhere strongly. Some years ago, Willingham and his coworkers7 showed that when the substrate was weakly adhesive for the cells, they did not spread and did not form stress fibres. When the same cells were induced to adhere tightly, they flattened on the substrate and prominent stress fibres appeared. Tight adhesion to the underlying substrate appeared to be the key to their appearance. Couchman and Rees1 reached a similar conclusion in their study of fibroblasts migrating from explants.

How might tight adhesion to a substrate induce the formation of stress fibres? One possibility is that the tight adhesion itself restricts or sterically inhibits the local movements of surface membranes. In turn, this might permit an ordering of the adjacent cytoskeletal elements into stress fibres — one that would not occur in a

region of cytoplasm that was in a more dynamic state, such as that underlying a ruffling membrane. An alternative explanation I find preferable is that stress fibres arise within a cell because it attempts to pull against a point of tight adhesion to the substrate. Since the substrate is a plastic culture dish, tension will develop. This will result in the alignment of individual microfilaments and possibly also in the recruitment of additional filaments to the bundle that develops. Thus the more strongly a cell adheres to a substrate the greater is the tension and the larger the resulting stress fibre. Several lines of evidence are consistent with this view.

Wohlfarth-Botterman and Fleischer8,9 showed that tension will induce large bundles of microfilaments in the protoplasmic strands of Physarum when these are made to contract under isometric conditions. The microfilament bundles, reminiscent of the stress fibres of fibroblasts, are not induced, however, during isotonic conditions. Physarum is phylogenetically far from cultured fibroblasts, but it may reveal a principle of non-muscle actomyosin systems. When stress fibre contractility in fibroblasts has been studied, isotonic contraction (that is, shortening) has been looked for, but the failure to observe this in live cells is hardly surprising if tight adhesions to the substrate make shortening impossible. Strong adhesions would impose isometric conditions on a contraction if the

Only when these adhesions have been weakened, as might be expected in cell model studies3,4, would shortening of stress fibres be observed.

That tension on the substratum is generated has been shown by Harris and co-workers10,11, who introduced flexible silicone rubber substrates to study cell movement. Highly motile cells, such as leukocytes, are unable to deform the flexible substrate during their movements. but more sedentary cells such as fibroblasts cause extensive wrinkling of the rubber, indicative of considerable tension. It seems most likely that stress fibres are the cellular structures responsible for generating this tension. Cells without stress fibres, even though they may move rapidly on the flexible substrate, appear unable to generate sufficient tension to wrinkle it. On the other hand, those cells that induce wrinkles beneath them tend to show large microfilament bundles often running at right angles to the wrinkles (unpublished observations). If the cells are rounded up with trypsin, the wrinkling (that is, the tension) is released11 and others have shown that these conditions also result in the rapid disassembly of stress fibres (see, for example, ref. 4). To generate the wrinkle some shortening of the stress fibres must occur; but even here a considerable element of the contraction must be isometric, since once formed the wrinkles are held for long periods of time, although they will snap back if the cell's adhesion to the rubber is released, indicating a sustained tension both in the rubber and the cellular elements causing it to wrinkle.

In conclusion, it would seem that stress fibres have little to do with cell migration. Several lines of evidence suggest that these structures are contractile but that in cultured cells this contraction is isometric rather than isotonic. It seems likely that the tension generated at points of tight adhesion to the substrate contributes to the formation of these bundles of actin microfilaments. In future it will be important to investigate further the conditions in which stress fibres appear in the body, and it will be particularly relevant to examine locations where tight adhesion and isometric tension might be expected to occur.

# Order or disorder in the structure of glass?

from S.R. Elliott

THE question posed in the title has provided a recurrent theme in the study of the structure of non-crystalline solids since the seminal work of Zächariasen in 1932. The absence of long-range order (periodicity) is a prerequisite for an amorphous material. The point at issue. therefore, is what degree of short- or medium-range order is present, if at all, in a glass? Is the structure of non-crystalline materials completely random and chaotic, or are there, as Zachariasen supposed for covalent materials, well defined structural units (for example, SiO<sub>4</sub> tetrahedra in SiO<sub>5</sub> glass) which are themselves randomly connected together?

Much evidence from diffraction and other experiments shows that covalently bonded amorphous solids do possess a strong degree of local order (that is, structural units), but controversy still exists over the degree of medium-range order whether the units are completely randomly connected together, or whether there exist preferred orientations, just as in the crystalline forms.

It is generally accepted, following Zachariasen, that the structure of directionally bonded (that is, covalent) amorphous solids can be well represented by a 'continous random network' (CRN), in which say for SiO<sub>2</sub>, SiO<sub>4</sub> tetrahedra are connected together at the apices through the oxygen atoms, such that every Si is surrounded by four O atoms, and every O is surrounded by two Si atoms, although the bond-angle subtended at the O atom may subtend a wide range of values. The SiO<sub>4</sub> tetrahedra is relatively well defined but there exists some uncertainty in the Si bond-angles, and the relative orientation of units is not at all well defined. A further complication arises for multicomponent systems since a single diffraction experiment only gives an average picture of the structure, being a sum of say, the individual Si-Si, Si-O, O-O pair correlation functions, so that only a limited amount of unambiguous structural information can be obtained.

For these reasons, a recent paper by Daniel and Leadbetter1 makes an interesting contribution. They studied an amorphous elemental system, arsenic, by means of X-ray diffraction. Amorphous arsenic (a-As) has been much studied in the past (see ref. 2 for a review), and is of interest because of its position in the Periodic Table midway between a-Si (used for solar cells) and a-Se (the active component in the Xerox process). However, in contrast to previous studies, Daniel and Leadbetter studied the molecular form of a-As. It is well known that As vapour consists of tetrahedral As<sub>4</sub> molecules, and if this vapour is condensed on a substrate held at 30K, an amorphous

form is produced consisting of a packing of As, molecules, bonded together by van der Waals' forces. Thus, in this case, the local order is extremely well defined (that is, the As<sub>4</sub> tetrahedron), and in principle the medium-range order of the amorphous solid can be explored directly, since the local structure is known accurately. A model whereby all the As4 tetrahedra are randomly oriented does not give peaks in the angular dependence of the scattering intensity in the same positions as those observed experimentally, implying there is a considerable degree of correlation between molecules in the way they pack. Instead, it appears that the molecules of As<sub>4</sub> prefer to pack in a slightly distorted, staggered face-to-face configuration. Similar substantial correlations are found in other (liquid) molecular systems, such as P and CC1<sub>4</sub>.

Another interesting point is the observation that molecular amorphous arsenic is structurally unstable, even at temperatures as low as 77K. The highly strained As<sub>a</sub> molecules, with bond-angles of 60°, irreversibly polymerize to form a cross-linked network, which has an X-ray diffraction pattern very similar to that of bulk a-As, which has a bond-angle of 98° and whose structure can be well simulated by a CRN<sup>2</sup>. This amorphous-amorphous transition is interesting in that it involves a distinct change in medium-range order: peaks in the real-space correlation function separate much further in the molecular form than in the polymerized material.

This work has considerable bearing on another commonly studied amorphous system, the As, S, system. This, unlike As itself, readily forms a glass by quenching of the melt, but can also be formed into amorphous thin films by vacuum evaporation. However, the stable vapour species is the almost spherical As<sub>4</sub>S<sub>4</sub> molecule, not the As<sub>4</sub>S<sub>6</sub> molecule which would preserve stoichiometry, and indeed Daniel and Leadbetter in an earlier paper<sup>3</sup> studied the structure of evaporated amorphous thin films of 'As,S,' and concluded that the structure is composed of a packing of As<sub>4</sub>S<sub>4</sub> molecules. Just as in the case of elemental As films, the As<sub>4</sub>S<sub>4</sub> molecules appear to pack in a highly correlated manner, but detailed interpretation is made difficult because of the two atomic species present and also because of the spherical nature of the molecule concerned.

Evaporated thin films of As<sub>2</sub>S<sub>3</sub> (or other alloys containing S or Se) are interesting because they exhibit both thermally and photo-induced structural changes. Like molecular As, the As-deposited films polymerize irreversibly on annealing, the

S.R. Elliott is in the Department of Physical Chemistry, University of Cambridge, Lensfield Rd, Cambridge CB2 1EP.

material becoming more chemically ordered in the process, as shown by X-ray diffraction<sup>3</sup> and EXAFS studies<sup>4</sup>. These materials are semiconductors, and irradiation by band-gap light also serves to induce polymerization, the so-called 'irreversible photostructural effect'. More mysterious, however, are the reversible structural changes induced by band-gap radiation on well annealed films and melt-quenched glasses of the same materials. These structural changes, on the scale of about 6Aappear to be smaller than those encountered in the irreversible effect and are accompanied by various optical

changes<sup>5</sup>; they can be annealed away by heating the sample to the glass transition (softening) temperature, whereupon reexcitation induces the same effect. The nature of these structural changes remains completely unknown. Perhaps when we understand the medium-range order present in glasses we might begin to understand this effect too!

# Calcium and calmodulin in Kyoto

from Robert S. Adelstein

Many diverse biological processes are regulated by the concentration of intracellular calcium, including cell motility and the synthesis and degradation of biologically important peptides and nucleotides. The effects of calcium are often mediated by the small (molecular weight 16,500), acidic protein calmodulin, which appears to be ubiquitous throughout much of the plant and animal kingdoms. Calmodulin contains four binding sites for calcium which become occupied at a calcium concentration of 10-6 M, a level corresponding with the onset of many calcium-mediated processes in cells. In marked contrast to the calcium-free molecules, the complex of calcium and calmodulin is capable of binding to and actvating numerous proteins with different biological activities. The mechanism and consequences of the binding of calcium to calmodulin were discussed in a meeting\* in Kyoto, Japan this past summer.

There was general agreement that positive cooperativity has a role in binding the second Ca<sup>2+</sup> to calmodulin (K. Yagi, Hokkaido University; J. Haiech, Montpellier University). It was further proposed that the binding of all four Ca<sup>2+</sup> to calmodulin is not random, but occurs in a specific sequence. Two enzymes that are activated by calmodulin, cyclic nucleotide phosphodiesterase and myosin kinase, appear to require the species with four Ca<sup>2+</sup> bound.

A major theme recurring throughout the meeting was the interaction between two major intracellular regulators: Ca<sup>2+</sup>, which is often coupled to calmodulin, and cyclic nucleotides, which are coupled to enzymes catalysing covalent phosphorylation. The kinetic analysis of the regulation of cyclic nucleotide phosphodiesterase by calcium and calmodulin was

presented by J. Wang (University of Manitoba) and his model used to explain the highly cooperative activation of phosphodiesterase by Ca<sup>24</sup> -calmodulin.

In the control of serotonin biosynthesis (Yamauchi and Fujisawa, Asahikawa Medical College), both tyrosine and tryptophan hydroxylases appear to be regulated by a Ca2+-calmodulindependent phosphorylation which promotes the binding of a separate activator protein. This heat-labile activator has a molecular weight of 70,000, is composed of two subunits of 35,000 and binds to the phosphorylated species of hydroxylase only, bringing about a twofold increase in enzyme activity. Additional activation by cyclic AMPdependent phosphorylation at other sites provides a separate mode for regulating these enzymes.

Y. Takai and Y. Nishizuka (Kobe University School of Medicine) described a calcium-dependent but calmodulin-independent membrane-bound kinase. This enzyme, which has now been purified from rat brain to near homogeneity, has a molecular weight of 77,000 and has been named C-kinase. It requires micromolar concentrations of Ca2+ and phospholipid for its activation, but contains no calmodulin, nor is it activated by exogenous calmodulin. Instead, a small quantity of unsaturated diglyceride increases the affinity of enzyme for Ca2+ as well as for phospholipid. The hydrolysis of phosphatidylinositol to phosphatidylserine and diacylglycerol, which can be induced by a number of different extracellular messengers, is directly coupled to its activation. The presence of relatively large amounts of protein kinase C activity in brain, platelets and other tissues and the interaction of this system with the cyclic GMP-regulatory system, suggests great promise for further studies.

Ca<sup>2+</sup> - and cyclic nucleotide-mediated reactions appear directly coupled at the level of their receptor proteins (C. Klee,

NIH). In brain extracts, calmodulin interacts in a Ca<sup>2+</sup>- dependent fashion with the regulatory subunit of cyclic AMP-dependent protein kinase.

One of the best examples of the coupling of the Ca<sup>2+</sup>-calmodulin regulatory systems with cyclic AMP-mediated regulation is that of smooth muscle. Myosin kinase, the enzyme regulating phosphorylation of smooth muscle myosin, is a substrate for cyclic AMP-dependent protein kinase (R. Adelstein, NIH) and phosphorylation of myosin kinase decreases its activity by decreasing its ability to bind calmodulin.

The role of calmodulin in regulating muscle contractile proteins was discussed by several investigators. Calmodulindependent phosphorylation of the 20,000 molecular weight light chain present on both heads of a single smooth muscle myosin molecule appears to be required before the Mg2+-ATPase activity of either head can be activated by actin (D. Hartshorne, University of Arizona). Using tracheal smooth muscle (J. Stull, University of Texas) an increase in tension was found to be paralleled by an increase in myosin phosphorylation; however, consistent with the results of Dillon et al. (Science 211, 495; 1981), it was possible to maintain isometric tension despite a decrease in the state of myosin phosphorylation.

S. Kakiuchi (Osaka University Medical School) presented evidence that calmodulin binds to spectrin, a component of the erythrocyte membrane, and suggested that the interaction might be involved in maintaining the normal shape of the red cells. He also reported the presence in gizzand smooth muscle of a novel protein (molecular weight 150,000) that binds to calmodulin in the presence of  $10^{-6}$ M Ca<sup>2+</sup> but binds to actin at low (< $10^{-7}$ M) Ca<sup>2+</sup> concentrations. The protein might inhibit the ability of actin to polymerize at low Ca<sup>2+</sup> concentrations.

Pharmacological aspects of the calmodulin system opened the meeting. F. Vincenzi (University of Washington) reappraised the action of neuroleptic drugs, particularly phenothiazines on calmodulin function. Some presumed calmodulin antagonists as well as neutral and acidic lipids seem to act directly on activatable enzymes, possibly interacting with hydrophilic regions of calmodulin-binding sites.

H. Hidaka (Mie University Medical School) presented studies of naphthalene-sulphonamide derivatives (W-7 and W-5) as antagonists of calmodulin action. These ampiphilic compounds appear to be more selective for calmodulin than phenothiazines with much less effect as general membrane perturbants. Treatment of cultured Chinese hamster overy cells

The symposium on Revent Advances in  $Ca^{2+}$  and Cell Function; Calmodulin and Intracellular  $Ca^{2+}$ -Receptors was held in Kyoto, Japan and organized by S. Kakiuchi (Osaka University Medical School) and H. Hidaka (Mie University School of Medicine).

with W-7 at moderate concentrations was shown to prohibit cell growth, arresting the cells in late G<sub>1</sub> phase. Using <sup>3</sup>H-labelled W-7, its distribution *in vivo* was shown to be similar to that of calmodulin under

conditions where growth arrest was obtained — suggesting that calmodulin may provide Ca<sup>2+</sup> -dependent regulation of functions required for the cells commitment to replication and division.

carcinogenicity is, in general, independent of metabolic action.

# Environmental nitrosamines and cancer

from Valda M. Craddock

It is now twenty-five years since dimethylnitrosamine was shown to cause liver cancer in rats in the historic experiments of Barnes and Magee. Tumours have now been shown to be induced by a wide variety of N-nitroso compounds in many species of animal and there is no reason to believe that man will prove to be an exception. There is also no doubt that man is exposed to these potent carcinogens. They frequently occur in industry and are widespread in the environment. Clearly, it is important to find out where the nitroso compounds come from, whether the levels found represent a hazard for man, what can be done about them and what the cellular and molecular mechanisms are by which they cause cancer. Progress in these areas was

discussed at a recent conference\* in Japan.

At previous meetings, emphasis had been on methods for the detection and estimation of nitrosamines when present in complex biological material. In the past, several reports of nitrosamines in the environment have proved to be false alarms when more specific analysis showed the presence of related chemicals. The situation at present is that volatile nitrosamines can be analysed by gas chromatography/thermal energy analysis. With non-volatile nitrosamines, preliminary formation of volatile derivatives is necessary.

N-nitrosoamines are likely to be formed wherever amines, secondary or tertiary, encounter nitrite. N-nitrosamides result from similar reactions with amides. Both types of compound are potent carcinogens. Nitrosamines are relatively stable and require metabolic activation to form the ultimate carcinogen; nitrosamides on the other hand are unstable, and the site of

Much good work done in detecting environmental nitrosamines comes from the German Cancer Centre (Preussmann, Heidelberg). Nitrosamines in beer were first detected in Germany. They are formed by the reaction of amines in barley with nitrous fumes from the fuel used to heat barley during the malting process, and can be dramatically reduced by changing the source of the heat. The nature of the amines involved is being elucidated (Wainwright, Brewing Research Foundation, Nutfield). Nitrosamines have been detected in rubber, including the rubber used in the manufacture of babies' dummies (Spiegelhalder and Preussmann, German Cancer Centre, Heidelberg). The use of alternative retarders, or of 'safe' amines, should reduce this hazard. Relatively high concentrations of nitrosamines have been found also in cutting oils (Keefer, NIH), and it is again possible to suggest methods for their elimination. Cosmetics are known to contain nitrosamines, and here the situation is less clear. The fact that female facial skin is not a high cancer incidence area is not necessarily a reassurance; N-nitroso compounds can be absorbed through the skin and cause cancer elsewhere. On the whole, however, the meeting was

#### 100 years ago

#### THE VOYAGE OF THE "VEGA" AROUND ASIA AND EUROPE

By A.E. Nordenskjöld (Macmillan & Co., 1881)

THE voyage of the *Vega* will be in many respects one of the most memorable events in the history of navigation. For the first time a continent has been circumnavigated, so far as authentic record goes, and at last the North-East Passage has been won, after heroic efforts begun nearly three and a half centuries ago. But the voyage will be still more memorable by the two rich volumes in which it finds copious record, volumes which have scarcely a parallel in the whole literature of geographical exploration.

In one chapter, Baron Nordenskjöld has collected all the information attainable on Steller's sea-cow (Rhytina Steller'), which on Steller's visit to Behring Island in 1741 was found pasturing in large herds on the abundant sea-weed on the shores of the island. Twenty-seven years after, not a specimen was to be found, and it was believed to be then

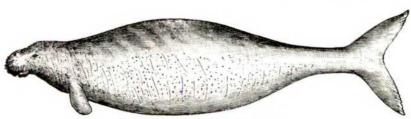

Fig. 10.-Reconstructed form of the sca-cow.

extinct. But Baron Nordenskjöld adduces evidence to prove that a specimen was seen twenty-seven years ago, though there can be little doubt that it has really gone the way of the mammoth. The Baron does not believe that its extinction is due to the destruction by hunters, but that it was a survival from a past age doomed to extinction, which overtook it when driven from its pastures on the shores of Behring Island.

"Steller's sea-cow (Rhytina Stelleri, Cuvier) in a way took the place of the cloven-footed animals among the marine mammalia. The sea-cow was of a dark-brown colour, sometimes varied with white spots or streaks. The thick leathery skin was covered with hair which grew together so as to form an exterior skin, which was full of vermin and resembled the bark of an old oak. The full grown animal was from twenty-eight to thirty-five English fect in length and weighed about sixty-seven cwt. The head was small in proportion to the large thick body, the neck short, the body diminishing rapidly behind. The short fore-leg

terminated abruptly without fingers or nails, but was overgrown with a number of short thickly placed brush-hairs; the hind-leg was replaced by a tail-fin resembling a whale's. The animal wanted teeth, but was instead provided with two masticating plates, one in the gum the other in the under jaw. The udders of the female, which abounded in milk, were placed between the fore-limbs. The flesh and milk resembled those of horned cattle, indeed in Steller's opinion surpassed them. The seacows were almost constantly employed in pasturing on the sea-weed which grew luxuriantly on the coast, moving the head and neck while so doing much in the same way as an ox. While they pastured they showed great voracity, and did not allow themselves to be disturbed in the least by the presence of man. One might even touch them without their being frightened or disturbed. They entertained great attachment to each other, and when one was harpooned the others made incredible attempts to rescue it.'

From Nature 25, 22 & 29 December, 1881.

reassuring in that it showed competent groups to be tracking down environmental nitrosamines, and to be suggesting realistic methods for reducing their formation.

More difficult to elucidate is the formation of nitrosoamines in vivo. Amines are ubiquitous in biological material, and therefore occur in vegetable and animal food. Nitrate occurs in plant material and in water, and can be reduced to nitrite by bacteria in the gastrointestinal tract, especially in the mouth. Hence amines and nitrite are likely to react together in the stomach. The amount of nitrosamines formed depends on the nature of the stomach contents, and has been shown to be altered by gastroduodenal diseases (Walters, Food Research Association, Leatherhead). As nitroso compounds are usually rapidly metabolized, and are formed in small amounts at any one time, their estimation is difficult. An ingenious method is being developed in which the naturally occurring amino acid proline is given to experimental animals or to human subjects. Nitrosation of this amine yields N-nitrosoproline, a nitrosamine which is apparently not carcinogenic and which is excreted in urine. Determination of urinary N-nitrosoproline could therefore give a measure of the formation of N-nitroso compounds in man (Ohshima and Bartsch, International Agency for Research on Cancer, Lyon). Where reduction of the nitrate content of food would lead to other problems, as in the case of cured meat, it is possible to add compounds, such as ascorbic acid, which, in certain conditions, reduce nitrosamine formation (Tannenbaum, MIT).

Many useful drugs are amines which can give rise to carcinogenic nitrosamines. Here the only solution at present seems to be a risk/benefit evaluation with each drug, possibly with each patient. To take cimetidine for dyspepsia, whether or not an ulcer is known to be the cause, or to take this drug indefinitely to prevent recurrence of an ulcer, requires justification.

The levels of nitrosamines to which man is exposed may be low at any one time, but the effect of one nitrosamine given at different times, and of different nitrosamines administered simultaneously, can be additive. Hence to ask each time nitrosamines are detected in a product, "is this level likely to constitute a hazard to man?", is meaningless. The nitrosamines consumed in Scotch whisky must be added to those in bacon, mushrooms, cigarette smoke, cosmetics, and to the nitrosamines formed *in vivo*.

While the entire population is probably exposed to nitrosamines in some form, everyone does not get cancer. The more that is understood about the means by which nitrosamines cause cancer, the more it is possible to detect high-risk individuals or groups, and to take protective measures. The best working hypothesis is that metabolism of nitrosamines leads to the formation of alkylating species which react

with DNA and cause mutation-like events which disrupt certain control mechanisms in the cell.

The first biochemical step in carcinogenesis, the metabolism of the aliphatic, heterocyclic, or aromatic nitrosamines, has been studied by chemical in vivo and in vitro methods (Okada, Tokyo Biochemical Research Institute; Preussmann). Oxidation occurs at various carbon atoms, but it was pointed out that the major metabolites may represent genuine detoxication reactions, while metabolites produced by minor pathways, and which would be more difficult to detect, may represent the ultimate carcinogens (Lijinsky, Frederick Cancer Research Center, USA). The effect of replacing certain hydrogen atoms in the nitrosamine by deuterium, with the consequent slowing of oxidation at this site, on the carcinogenicity of the nitrosamine gives suggestive data on the relevant reactions (Lijinsky). The effect of components of a normal diet, for example alcohol, on metabolism of nitrosamines is obviously of much relevance in assessing the role of

these compounds in human cancer (Hecht, Maylor Vana Institute, Valhalla, USA). Also the occurrence in cooked food of chemicals which increase the mutagenicity of nitroso compounds, and cause previously inactive compounds to become mutagenic, is a cause for concern (Wakabayashi, National Cancer Centre Research Institute, Tokyo).

One in four of the population develop cancer, and much of this is thought to be due to environmental agents (Higginson, International Agency for Research on Cancer, Lyon), which are, at present, mainly unidentified. The universal distribution of nitrosamines and the variety of tumours they are known to induce in animals make it difficult to correlate exposure with any particular human cancer. However, there is now epidemiological evidence that strongly suggests the association of N-nitroso compounds with oesophageal, bladder and stomach cancer. The fact that a variety of preventive measures are being taken to reduce exposure is a cause for special congratulation to those engaged in this work.

#### Movement in membranes

from A.G. Lee

IT is now ten years since Singer and Nicholson unveiled their fluid mosaic model of the biological membrane to an admiring world. To have survived so long is a complement both to the basic correctness of the model and to its flexibility. Predictably, much work over the intervening period has been concerned with trying to reduce this flexibility and achieve a state from which it is possible to make concrete predictions about membranes. Progress has, however, been slow and the gap to be bridged between simple model systems and studies of intact membranes remains large.

One source of difficulty is obvious — the membrane is a complex mixture of components, and one of the keys to success in the molecular sciences is to avoid complex mixtures. In the long run, this problem has to be faced in membrane studies, since an understanding of how the various components of the membrane mix together is one of the central issues of membrane biology. All that we can say with certainty at present is that the components of the membrane will not be mixed randomly. but the exact nature of the resulting order is unclear. Order in the membrane will follow in part from the equilibrium thermodynamic mixing properties of the components of the membrane, but it could also reflect the role of larger-scale structures in

preventing any such equilibrium mixing. The latter possibility is illustrated in a recent study by Dragsten, Blumenthal and Handler (see this issue of *Nature*, p.718).

Epithelial cells form sheets which serve as permeability barriers in organs such as kidney and the intestine. To be effective as a permeability barrier the cells have to be linked together by an elaborate junctional complex, called a tight junction, which forms a continuous, belt-like, highly impermeable structure around the cells. A further property of the cells is that they are asymmetric, with channels, pumps and receptors being different on the apical (mucosal) and basolateral surfaces. It has been suggested that this asymmetry is possible because the tight junction acts as a barrier to lateral diffusion in the membrane. Using the technique of fluorescence photobleaching, Dragsten and his colleagues have shown that cell surface sites in epithelia labelled with lectins do not diffuse laterally at all, so that no barrier is required to maintain an asymmetric distribution of these components. They also found a much more interesting result using lipid labels added to monolayers of epithelial cells. A fluorescently labelled phosphatidylcholine, for example, was free to diffuse in either the apical or basolateral surface (depending on to which side of the monolayer it was added) but was unable to pass through the tight junction from one surface to the other. However, if the epithelial monolayers were dispersed into

A.G. Lee is a lecturer in the Department of Biochemistry, University of Southampton, Southampton SO9 3TU.

suspensions of single cells by disruption of the tight junction, then phospholipid could freely diffuse over the entire cell surface.

Not all amphipathic molecules are segregated in this way by the tight junction, and some can freely diffuse from one surface of the cell to the other. These differences appear to be correlated with the ability of the label to undergo the so-called 'flip-flop' motion between the two halves of the bilayer membrane. Phospholipids are known to undergo this motion very slowly, and a phospholipid added to epithelial cells remains in the outer half of the membrane. Some amphipathic molecules can, however, rapidly flip between the two halves of the membrane. and it is these labels that can diffuse past the tight junction. It therefore seems that the tight junction acts as a diffusion barrier only for the outer half of the membrane and so allows the epithelial cell to maintain a difference in phospholipid compositions between the outer halves of the apical and basolateral surfaces of the cell.

Restricted diffusion of phospholipids and other amphipathic compounds can also result from the simple equilibrium mixing properties of the components of the membrane. One clear example has been studied by McConnell and his colleagues over the last few years (Recktenwald and McConnell Biochemistry 20, 4505; 1981). There is now much evidence that in mixtures of phospholipids and cholesterol some kind of highly ordered structure is formed. Although the full details are still controversial, the suggestion is that the structure resembles a ploughed field with furrows of pure phospholipid separated by ridges made up of a mixture of phospholipid and cholesterol. Diffusion will then tend to occur preferentially parallel to the ridges and furrows rather than across them. In extrapolating this conclusion to real membranes, many of which contain high concentrations of cholesterol, it is of course necessary to consider the effects that proteins might have. Effects of protein on the diffusion of amphipathic molecules are considered by Laggner in a recent issue of Nature (294, 373; 1981).

If spin-labelled fatty acids are incorporated into membranes at relatively high concentrations, then the ESR spectra of the spin labels become broadened as a result of motion of one spin label relative to its neighbours. Laggner has observed that this concentration broadening is less in membranes of sarcoplasmic reticulum than in lipid bilayers prepared from phospholipids extracted from sarcoplasmic reticulum. He suggested that this could reflect the presence of two phospholipid environments - bulk phospholipid and annular phospholipid adjacent to membrane proteins, with only the fatty acid incorporated into bulk phospholipid being free to diffuse within the membrane. The pattern of diffusion of amphipathic molecules in biological membranes is clearly complex.

# The gassiest comet?

from David W. Hughes

COMET BRADFIELD, 1979X, is the comet in question and recent measurements indicate that the ratio between the mass of gas and the mass of dust emitted by this comet per unit time is higher than that measured for any other comet. The underlying message is that no two comets seem to be the same and when they near the Sun their gas and dust emission depends on a whole range of factors. Among the most important of these must be the time interval between perihelion passages, the orientation of the nucleus spin axis with respect to the orbital plane and the evolutionary stage the comet happens to be in.

Knowledge of gas production has been greatly improved by two factors. First, high-resolution spectra of bright comets can be obtained from the International Ultraviolet Explorer (IUE) satellite. The satellite has two echelle UV spectrographs that have a total wavelength range of 1.150-3,200 Å and a possible resolution of 0.2 Å, over a rectangular field of view of 10×15 arc s. Data have been collected from objects as faint as 17th magnitude. Second, an upsurge in interest in the UV end of the spectrum has helped the groundbased astronomer and it is now realized that reliable, absolute photometry can be carried out from a good site down to wavelengths of around 3,080 Å.

Considerable extinction occurs in the atmosphere at low wavelengths due to Rayleigh scattering by air molecules, aerosol scattering by suspended particles and molecular absorption by ozone. Most of the ozone resides between the altitudes 10 and 35 km and the column density varies with season and latitude. Its contribution to extinction is, for example, 20 per cent smaller at the latitude of Hawaii than at the latitude of Flagstaff, Arizona. Unfortunately the extinction caused by Rayleigh and aerosol scattering varies exponentially as a function of height - for UV observations the higher you are the better. Extinction can, however, be measured by making repeated observations of a standard star as it rises and sets. The results obtained vary from 80 to 20 per cent as the wavelength increases from 3,100 to 4,100 Å.

Ground-based observations of comet Bradfield have been made by Michael F. A'Hearn (University of Maryland), Robert L. Millis (Lowell Observatory, Arizona) and Peter V. Birch (Perth Observatory, Australia) and their results have been published in a recent edition of *The Astronomical Journal* (36, 1559; 1981).

Comet Bradfield came very close to the Earth and although it was not unusually

David W. Hughes is in the Department of Physics at the University of Sheffield, Sheffield S3.7RH

luminous, it was possible to make detailed photometric measurements from a time just after its discovery, when it was 0.57 AU from the Sun, up to the time when it was 1.65 AU away. All observations were postperihelion. The unusual apparition geometry meant that the comet quickly changed its position on the celestial sphere and had to be observed progressively from Perth, Australia; Mauna Kea, Hawaii; and Flagstaff, Arizona. Photometric measurements were made of the comet using a series of filters with pass bands of around 100 Å. The coma of the comet contains many gas molecules which undergo fluorescence excitation by solar radiation. Filters centred on 3,085, 3,365, 3,870, 4,060, and 5,115 Å pick up the radiation from OH, NH, CN, C3 and C2 respectively. The dust-scattered continuum was sampled by using filters centred at wavelengths of 3,300, 3,675 and 5,240 Å.

Using a specific coma model the authors converted the observed cometary molecule column density to a value for the total number of molecules in the coma and then, by dividing by the lifetime of the species, to a value for the production rate from the nucleus. To check their work they compared their ground-based observations of the production of OH with those determined from the IUE spacecraft. The agreement was excellent.

The production rate of all molecular species was found to vary as  $r^{-3.2}$  where r is the heliocentric distance of the comet. This is remarkably steep and contrasts with the  $r^{-2}$  variation found for comet West. One suggestion is that the nuclei of the two comets differ. Bradfield is perhaps covered with an outer 'frosting' of relatively volatile material. However, frosting is generally thought to be associated with a long residence  $(10^5-10^7 \text{ yr})$  in the boundary regions between stars, whereas comet Bradfield has an orbital period of only about 300 yr. Maybe the surface of the nucleus is heterogeneous or suffers from the buildup of an insulating crust.

The gas to dust ratio of the comet was found to be higher than for any other comet observed previously. The equivalent widths of certain C<sub>2</sub> Swan bands indicate that this could have been as high as 22 when the comet was about 0.8 AU from the Sun, decreasing to about 3 at 1.65 AU. This is three to four times greater than values observed for previous very gassy comets such as P/Encke and comet Kohler (1977 XIV).

Changes occurred in the relative molecular production rate as a function of heliocentric distance. The comet was CN rich when it was discovered at  $r = 0.57 \,\mathrm{AU}$ . Over the range  $0.6 < r < 1.0 \,\mathrm{AU}$  the abundance ratios were normal and they stayed constant. However, a peak in  $C_2$  production relative to CN occurred around 1 AU and OH and  $C_2$  decreased relative to  $C_3$  and CN as the comet went further away.

# REVIEW ARTICLE

# Long-term growth and cloning of non-transformed lymphocytes

William E. Paul, Benjamin Sredni & Ronald H. Schwartz

Laboratory of Immunology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

The diversity of lymphocytes has made it difficult to study the properties of a specific lymphocyte type. Here we describe methods used in long-term culture and cloning of T lymphocytes and discuss the potential uses of these cell lines in immunology.

ONE of the greatest obstacles to the understanding of the functions, regulation, cell biology and secreted products of lymphocytes is the enormous diversity of these cells. This diversity is accounted for by: (1) a series of distinct differentiation lineages, that is, B and T cells and their subpopulations; (2) a heterogeneity of differentiated states (resting, activated, memory and effector cells); and (3) a heterogeneity in the specificity of receptors individually expressed on distinct cells. The number of distinguishable specificities expressed by lymphocyte receptors is probably of the order of  $10^7$ . By taking into account the other two classes of heterogeneity, we may estimate conservatively that  $10^8$  distinct types of lymphocytes may exist among the  $\sim 10^{12}$  such cells in an adult human.

Obviously, the direct study of the properties of any specific type of lymphocyte is virtually impossible in such conditions. Traditionally, immunologists have resorted to methods such as the use of 'polyclonal' stimulants which activate most or all cells of a particular class. These approaches have yielded valuable information on lymphocyte physiology but the extent to which the results obtained reflect the reality of antigen-stimulated lymphocyte function is still uncertain. Sophisticated cell purification procedures such as fluorescence-activated cell sorting and the use of antibody-coated dishes, have made it possible to obtain cell populations of a substantial degree of purity, but these procedures by themselves cannot provide truly homogeneous cell populations. Recently, however, long-term culture and cloning of non-transformed immunocompetent lymphocytes has become possible. Here we review the methods of production of such long-term T-cell lines and the potential value of these lines in cellular immunology.

#### Culturing

It had been possible for some time to maintain functional thymus-dependent (T) lymphocytes in culture and to enrich such cultures with cells specific for a given antigen by repetitive stimulation with that antigen. Using this approach, T lymphocytes specific for protein antigens were propagated for periods of 3 months or longer<sup>1</sup> and cytotoxic T-cell lines maintained for periods >60 days<sup>2</sup>. However, such lines generally failed to expand to any substantial degree. It was the recognition that the growth of lymphocytes depended not only on contact with antigen but also on the presence of certain growth factors<sup>3</sup>, such as T-cell growth factor (TCGF or interleukin-2 (IL-2)), which opened the way to the large-scale growth and cloning of T lymphocytes. Various techniques are now available for developing and cloning long-term T-cell lines. Indeed, T lymphocyte lines of essentially all the major functional classes known, including helpers, amplifiers, cytotoxic cells and suppressors, have been prepared and dramatic results obtained with these lines are now being reported4.

Several different methods can be used to establish T lymphocytes in long-term culture. Perhaps the first, and still most widely

used, is to grow T lymphocytes from immunized donors for several weeks or more in the presence of antigen with exogenous growth factor(s), before attempting to clone them<sup>5</sup>. In general, T cells specific for foreign histocompatibility antigens—cytotoxic T cells and amplifier T cells-are grown with allogeneic irradiated stimulator cells whereas T cells specific for protein antigens are grown with antigen and irradiated spleen cells as a source of antigen-presented cells (APCs). A source of histocompatible APCs is particularly critical for cells displaying 'histocompatibility restriction' (see below). As well as presenting antigen, the added irradiated cells probably supply growth or differentiation factors including, but not necessarily limited to, interleukin-1 (IL-1). Cell growth is often quite vigorous in the presence of antigen, a source of an IL-2-containing growth factor and irradiated spleen cells. Cells grown in this way can often be established in long-term lines although they generally go through a period of 'crisis' when they stop growing or grow only slowly. The nature of crisis is not fully understood, but cells which survive it can be maintained in culture for periods of ≥3 vr (F. Fitch, personal communication). It has also been possible to establish cell lines using antigen and irradiated spleen cells, without the addition of an exogenous source of growth factor<sup>6,7</sup> This approach has been particularly successful in the establishment of helper cell lines. Presumably, in this case, IL-2 is produced by the irradiated spleen cells added to these cultures or perhaps by the line itself.

A second approach to the production of long-term T-cell lines is to grow cells as colonies in soft agar as soon as possible after they have been taken from an immunized donor. In this technique, T lymphocytes are stimulated in an initial suspension culture by the addition of antigen and a source of APC, generally in the form of irradiated spleen cells. After 3 days, these cells are distributed in the upper layer of a two-layer soft agar culture system; antigen is present in the lower layer. Colonies form in the soft agar and may be picked from day 4 to day 8. These colonies are then placed in microtitre culture dishes and grown in the presence of antigen, a source of irradiated APCs and an IL-2-containing growth factor. Lines can be established from such colonies with a relatively high frequency of success.

An alternative approach is to select cells for their functional properties rather than their antigenic specificity. For example, Nabel et al. have obtained cells from various sources (that is, fetal liver, bone marrow, thymus and spleen) and grown them with a series of different irradiated filler cells and growth factor-containing supernatants. By analysing the cultures thus obtained, they were able to produce a series of lines of which some mediated helper function, some suppressor activity and others natural killer (NK) activity.

#### Cloning

Each of these strategies for the establishment of long-term lines should be followed by a cloning technique if a cell population derived from a single progenitor is desired. Indeed, it can be anticipated that the longer the interval between the introduction of cells into culture and the time when cloning is carried out, the more likely it is that an 'unusual' cell may come to dominate a line. Consequently, it is desirable to clone as soon as possible, as in the technique described above for preparing lines from soft agar colonies.

Techniques used to clone long-term cell lines are of three general types. Perhaps the most widely used is limiting dilution cloning, in which the cells are diluted to low density (that is, 0.1 to 10 cells per well) and plated out in microtitre wells. In general, such techniques require the presence of some type of filler cell if the T cells are to grow and, for the approach to be useful, the frequency of wells which show cell growth should conform to that expected from Poisson statistics in the case of a single limiting unit responsible for cell growth. Even so, unless the cloning efficiency is quite high, it is advisable to repeat the cloning step before regarding a line as derived from a single progenitor. A second approach is to carry out soft agar colony formation in conditions where the number of antigen-presenting cells exceeds the number of the cultured cells plated. If the efficiency with which cultured T cells form colonies is high (and cases of 90% or greater have been reported10) then it is likely that progeny from such colonies are, indeed, members of a single clone. A third approach is to select a single T cell from a long-term line by micromanipulation or using a cell sorter and to grow a line from this cell. This is perhaps the most difficult but least ambiguous method.

#### T-cell growth factors

The preparation and study of long-term T-cell lines has produced interesting results. First, it has given great impetus to the study of factors regulating T-cell growth, two of which have been characterized in considerable detail. One of these, IL-1, is a macrophage product which seems to play an important part in the activation of some T cells, possibly by stimulating them to produce a second factor, IL-2 (refs 11, 12). Generally, the ability of IL-1 to stimulate T cells seems to depend on the presence of another stimulating agent, either antigen (or antigen-Ia complex) or mitogenic lectin. IL-1 can be obtained from macrophage tumour lines such as P388D1. Production of IL-1 by P388D1 depends on induction with agents such as phorbol myristate acetate (PMA). The technique of superinduction of P388D1 cells has recently provided sufficient IL-1, a protein molecular weight  $(M_r)$  15,000, for it to be purified to homogeneity<sup>13</sup>. In addition to the role of IL-1 as a T-lymphocyte activating factor (it was originally known as LAF), it seems also to function as an endogenous pyrogen<sup>14</sup> and as a stimulant of firoblast proliferation<sup>15</sup> and, thus, potentially may be responsible for much of the fibrosis seen in immune inflammation.

IL-2, a T-cell product which regulates T-cell growth, seems to act on T lymphocytes after they have been stimulated by antigen or by an antigen-Ia complex<sup>16</sup>. Recent studies<sup>17</sup> indicate that resting T lymphocytes lack membrane receptors for IL-2 but that stimulated T cells (that is, T-cell blasts) bear ~10,000 IL-2 receptors (per cell). The binding of IL-2 to T-cell blasts appears to be critical for their completion of the cell cycle.

IL-2 has been purified both from murine and human sources and from normal lymphoid tissue and tumours. In general, IL-2 production requires stimulation of the cell; both EL-4, a murine T-cell lymphoma, and Jurkat, a human T-cell leukaemia, secrete large amounts of IL-2 on induction with PMA. Human IL-2 is a glycoprotein of  $M_r$  15,000<sup>18</sup>; murine IL-2 has an apparent  $M_r$  of 30,000 by gel filtration<sup>19,20</sup> and 23,000 by SDS-polyacrylamide gel electrophoresis<sup>21</sup>.

One major question concerning the regulation of T-cell growth by IL-2 is whether cells which are sensitive to IL-2 also secrete it, perhaps in different phases of their growth cycle, or whether IL-2 production and IL-2 sensitivity are always properties of independent T-cell lines. There are clear cases of IL-2-dependent lines which do not produce IL-2, for example, the cytotoxic T-cell lines available in many laboratories, while certain lines, such as those which express allogeneic mixed

lymphocyte reactivity, produce IL-2 during growth. However, there has been no clearly documented case of an IL-2-sensitive, non-transformed line which also produces IL-2, although T cell tumours with these properties have been described 17,35.

#### T-cell physiology

Cloned T-cell lines have potentially great value in the study of T-cell physiology. They have already aided our understanding of the specificity of so-called 'histocompatibility-restricted' T cells and of the nature of the immune response (Ir) gene product. In general, cells which mediate helper, amplifier or delayed hypersensitivity functions, which proliferate in vitro to antigen, or which act as cytotoxic effector cells, seem to recognize antigen and a product of the major histocompatibility complex (MHC)<sup>22</sup>. The MHC product recognized in these reactions is often referred to as a restriction element. For helper, amplifier, delayed hypersensitivity and proliferating T cells, the restriction element is generally an Ia antigen. This is a two-chain molecule; genes for both chains are encoded in the I region of the MHC. For cytotoxic T cells, the restriction element is usually an H-2K. D or L antigen. The study of cloned long-term T-cell lines has provided unambiguous evidence that joint recognition of antigen and restriction element is the property of a single cell and not of two collaborating cells, one specific for antigen, the other for the restriction element.

Studies of cloned long-term lines of antigen-specific human T lymphocytes have established that they, too, demonstrate histocompatibility restriction<sup>23</sup>, a matter which had previously been in doubt for human T cells because of the difficulty in obtaining antigen-specific cells of the correct genotype and because the mixed lymphocyte reactions observed in cell mixing experiments gave confusing results.

Cloned mouse T-cell lines have been used to show that in heterozygous  $(F_1)$  individuals, restriction elements may be formed by the pairing of a product encoded by one parental haplotype and a product encoded by the other parental haplotype  $^{24.25}$ . There is chemical evidence of Ia antigens that are created by such genetic complementation  $^{26}$ . Clonal analysis suggests that clones specific for restriction elements created by complementation (heterozygous restriction elements) are only slightly less frequent than those specific for homozygous restriction elements. Indeed, the agreement between formation of both restriction elements and Ia antigens by complementation provides strong evidence that the Ia antigen is the restriction element. Similarly, using cloned T-cell lines to analyse the action of Ir genes, it has been possible to show that the products of these genes are also restriction elements and Ia antigens  $^{24}$ .

Finally, the use of cloned T-cell lines has provided insight into the provocative finding that the frequency of T lymphocytes specific for foreign MHC antigens (that is, capable of mediating mixed lymphocyte responses) is very high. It has been estimated that ~5% of the T lymphocytes of an inbred mouse are specific for the MHC antigens of any single foreign MHC haplotype. It has recently been shown<sup>27</sup> that a cloned cytotoxic T-cell line specific for an H-Y antigen and a self-MHC restriction element could also lyse cells of a specific foreign MHC type that did not express the H-Y antigen. Similarly, a clone of T cells from a mouse of MHC haplotype, H-2<sup>a</sup>, which could be stimulated to proliferate by dinitrophenyl-ovalbumin (DNP-OVA) in the presence of APC-expressing H-2a-encoded restriction elements, could also be stimulated to proliferate by APC-expressing H-2° antigens in the absence of DNP-OVA<sup>28</sup>. Thus, these antigen-reactive H-2<sup>a</sup> cells also mediate a mixed lymphocyte response to H-2s-encoded Ia molecules. Indeed, recent studies<sup>29</sup> suggest that a very large fraction of cloned antigenspecific, MHC-restricted T-cell lines are also responsive to foreign MHC antigens. Thus, it seems likely that a high frequency of alloreactive T cells is observed because alloreactivity may be a property of almost all MHC-restricted T cells. This will be of critical importance in understanding the chemical basis of T-cell antigenic recognition and the evolutionary forces which have shaped the T-cell repertoire.

Recently, the approaches used to grow long-term lines of T cells have also been applied to B cells. Lines of non-transformed, growth-factor dependent B lymphocytes of mouse<sup>30</sup> and human<sup>31</sup> origin have been propagated for periods of >10 months. The growth of these cells seems to depend on a growth factor produced by T lymphocytes but which is distinct from IL-2 (M. Howard et al. and W.E.P., submitted for publication, and B.S., B. Stadler, J. J. Oppenheim and W.E.P., unpublished observations). This factor has been termed B-cell growth factor (BCGF) and studies of its properties are now in progress. B cells grown in long-term culture can be stimulated to secrete immunoglobulin and human B-cell lines have been successfully cloned by limiting dilution.

#### **Potential**

We may anticipate that the use of cloned T-lymphocyte populations will be of great value in the functional, molecular and genetic characterization of T-lymphocyte receptors and will lead

to a more complete understanding of both the molecular basis and biological significance of histocompatibility restriction. We may also anticipate that a further understanding of the regulatory interactions of immunocompetent cells will come from the preparation of cloned lines of each cell type and from the analysis of the molecules that mediate these interactions. Furthermore, the application of this technology to human T<sup>3,22</sup> and B30 lymphocytes will have great importance in various clinical situations. Cloned T-cell lines will be valuable as tissuetyping reagents<sup>32</sup> and may have applications in specific therapy for certain infectious agents (J. M. Chiller, personal communication) and tumours 33.34

Much work remains to be done; it is particularly important to establish the extent to which such long-term cells are 'normal' (that is, how closely they resemble lymphocytes in vivo). It seems reasonable to predict that long-term lines of cloned lymphocytes will become standard tools of the cellular immunologist.

# The 1883 eruption of Krakatau

#### **Stephen Self**

#### Michael R. Rampino

NASA Goddard Institute for Space Studies, Goddard Space Flight Center, New York, New York 10025, USA

The 1883 eruption of Krakatau was a modest ignimbrite-forming event. The deposits are primarily coarse-grained dacitic, non-welded ignimbrite. Large explosions produced pyroclastic flows that entered the sea, generating destructive tsunami. Grain-size studies of the ignimbrite suggest that these explosions were not driven by magma-seawater interaction. The total bulk volume of pyroclastic deposits, including co-ignimbrite ash, is estimated to be 18-21 km<sup>3</sup>.

ALTHOUGH the paroxysmal eruption of Krakatau (or Krakatoa) in 1883 was very spectacular there are little data relating to the mechanism of the eruption, or to interpretation of the pyroclastic deposits in terms of modern volcanologic theory. Studies have concentrated on Anak Krakatau, a young cone growing in the 1883 caldera<sup>1</sup>, and not on the 1883 deposits. The idea of caldera formation by explosive removal of cone material has been revived<sup>2</sup> but we dispute this mechanism.

We report here results mainly from new field investigations at Krakatau during September 1979. We attempt to correlate the eruption sequence reported previously with the stratigraphy of the deposits to re-evaluate proposed mechanisms for the eruption.

Most interpretations of the Krakatau event rest on the studies 4. He was the first to propose that the huge explosions were caused by seawater coming into contact with the magma within the volcano. Deposits resulting from such phreatomagmatic activity for other eruptions are described elsewhere<sup>5</sup>. Verbeek also suggested that reaction with seawater caused the magma to froth, thus forming the extensive pumice ejected in the 1883 eruption. Although this latter interpretation is now seen to be incorrect, the question of interaction of the magma with seawater as a possible cause of the catastrophic explosions is still being debated2.6. However, the eruption is usually ascribed to such phreatomagmatic activity.

Later workers have recognized that the near-source deposits of the 1883 eruption were largely emplaced by pyroclastic flows: Williams and McBirney<sup>7</sup> suggested that these flows may have swept for some distance across the floor of the Sunda Straits. We now present evidence that the culminating event of the Krakatau eruption was the generation of pyroclastic flows by gravitational collapse of the eruption column after several

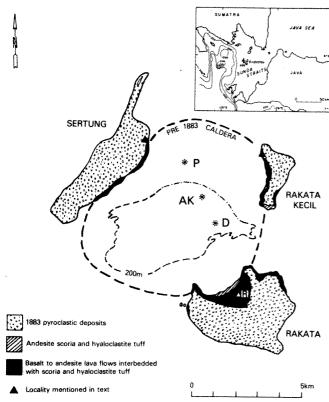

Fig. 1 Sketch map of Krakatau Islands showing prehistoric caldera, possible 1883 caldera outline (200-m isobath, lighter dashed line, dash-dot where conjectural) and simplified geology. large magmatic explosions. We discuss here the role of magmaseawater interaction during the eruption and suggest that the major tsunami that accompanied the eruption were produced when the pyroclastic flows entered the sea.

Before the eruption of 1883, Krakatau consisted of a large island 9 km long and 5 km wide constructed of three volcanoes, Perbuwatan, Danan and Rakata, situated along a fissure within a prehistoric caldera ~7 km in diameter. The surrounding smaller islands of Sertung (formerly Verlaten Island) and Rakata Kecil (Lang Island) are remnants of the rim of the prehistoric caldera (Fig. 1). Krakatau Island largely disappeared during the 1883 eruption, leaving only the southern portion of the cone of Rakata volcano (and a small rock pinnacle) exposed above sea level. The consensus of opinion is that the main vent or vents for the 1883 eruption lay between the vents of Perbuwatan and Danan. Our results are consistent with a vent location in this general area; the location of Anak Krakatau may be controlled by the 1883 vent and conduit.

The foundation of the Krakatau volcano is largely basaltic andesite to andesite composition<sup>9</sup>. The 1883 eruption produced a widespread deposit of non-welded dacitic ignimbrite which covers major portions of the present Rakata, Sertung and Rakata Kecil Islands.

#### Stratigraphy of the 1883 deposits

We have compared the stratigraphy of the pyroclastic deposits examined in the field with the contemporary eruption records compiled by Verbeek<sup>3,4</sup>, and with the later work of Stehn<sup>10</sup> and Williams<sup>8</sup>. The chronology of the eruption, tsunami, stratospheric effects, and the global spread and transport of long residence time 'dust' were documented in the Krakatoa Committee Report of 1888<sup>11</sup>.

A composite section of the pyroclastic deposits of the 1883 eruption is shown in Fig. 2. The stratigraphy of the airfall and

pyroclastic surge beds is based primarily on two localities on Sertung and Rakata Kecil Islands (Fig. 1), and the stratigraphy of the pyroclastic flow deposits (ignimbrite) is based on several cliff exposures on the western coasts of Rakata and Sertung Islands.

The 1883 eruption began with a period of intermittent mild explosive activity on 20 May 1883. Contemporary reports suggest that on 26 August 1883, at about 13h 00min LT the volcano went into an increasingly explosive phase of eruption, producing a more or less continuous eruption column through explosions at brief intervals ( $\sim 10$  min) (see Judd in ref. 11). The largest explosions during this stage of eruption were recorded at 17h 07 min on the evening of 26 August and 1h 42min, 2h 25min and 4h 43min on 27 August (Fig. 3; see Judd in ref. 11). The eruption column is reported to have been up to 25 km high during this interval. Ships within  $\sim 20$  km of the volcano reported heavy ash fall, with large pumice clasts (up to  $\sim 10$  cm diameter) (Judd in ref. 11).

The explosions produced fall units of dacitic pumice up to 20 m thick that are exposed on the islands of Rakata Kecil and Sertung. Pyroclastic surge deposits, found interstratified with the fall units, indicate that minor eruption column collapse during this stage of the eruption produced thin, low-density turbulent pyroclastic surges 12. All outcrops of the fall/surge deposits are very close to the source (only 2 or 3 km from the supposed vent) and it is inferred that the surges were fairly localized (with much material probably flowing onto or into the sea). The fall deposits were probably of sub-plinian type 13,14 and also of modest dispersal. For example, there were reports of only minor ash fall in southern Sumatra and western Java before the climax of the eruption of 27 August (ref. 11, p. 14). No pumice fall deposits were found beneath pyroclastic-flow and surge deposits on Rakata Island, only 6 km south-east of the vent, even though exposure was excellent. However, the axis of dispersal of the ash fall may have been directed to the west or south-west4.

On Rakata Kecil Island, an estimated 3 km from the source vent, two uppermost 5-6-m thick pumice fall units are welded to form a dark-grey coherent deposit, differing markedly in colour from the over- and underlying white dacitic pumice (Fig. 4a). Sparks and Wright<sup>15</sup> have described similar welded airfall tuffs

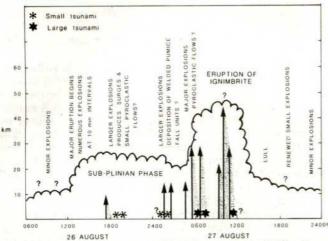

Fig. 3 Sequence of reported explosions and tsunami during 26-27 August 1883 (all times are local). Data from refs 3, 4 and 11. Relative magnitudes of explosions, as recorded by the Batavia gasometer, are indicated by lengths of arrows. Approximate eruption column heights given at left are not accurate to more than ±5 km. Travel times of tsunami from Krakatau to Java and Sumatra coasts estimated at between 30 min and 1 h (ref. 11).

of silicic composition; such tuffs are localized around the vent and indicate high rates of eruption and accumulation of pumice, but imply perhaps only moderate ( $<2\,\mathrm{km}$ ) heights for the gas-thrust part of the eruption column. This combination allows the hot, plastic pumice to sinter and agglutinate under its own weight on deposition. Grain-size analyses of the incipiently welded fall unit show it to be rather poorly sorted ( $\sigma\phi = 3.2$ ), and similar to many previously studied non-welded proximal pumice-fall deposits (Fig. 5).

That the pumice-fall deposits are relatively coarse grained compared with phreatoplinian<sup>5</sup> deposits (Fig. 5) suggests that, during the sub-plinian phase of the eruption, the Krakatau explosions were largely magmatic and did not involve significant interaction with seawater. The lithic-poor nature of most of the fall deposits also suggests that, during these early stages of the eruption, large-scale break-up and collapse of the volcanic edifice into the conduit (to allow access of seawater) did not occur. The surge deposits at Krakatau are also lithic poor and similar to the thin pumice-rich ground-surge deposits associated with other ignimbrite-forming eruptions and described from several other localities<sup>16</sup>.

At about 5h 30min on 27 August, the style of the eruption changed dramatically (Fig. 3). The first of five enormous explosions took place. Wharton<sup>11</sup> gives the times of the largest explosions as 5h 30min, 6h 44min, 9h 29min, 10h 02min and 10h 52min LT on 27 August; Verbeek<sup>3,4</sup> gives slightly different times (3–5 min later) based on a different reading of the gasometer tracing from Batavia, which fortuitously recorded the air waves from the explosions.

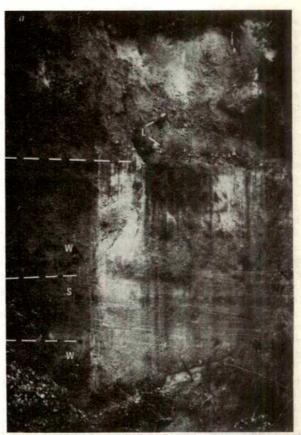

We suggest that each large explosion yielded a pyroclastic flow, almost instantaneously, by large-scale gravitational collapse of the eruption column. These flows moved rapidly off the island and into the sea. The four thick major pyroclastic flow units observed in the field (Fig. 2) probably correspond to the four largest explosions (Fig. 3; see ref. 10).

Material came from the vent between explosions, but was probably finer grained and not of significant volume. We may compare this with the Mt Ngauruhoe, New Zealand eruption sequence of 19 February 1975 (ref. 17) where after an initial period of more or less continuous magma flux, activity declined, then began again with a series of large explosions, each producing a small pyroclastic flow. We propose that the Krakatau eruption sequence was similar but on a much larger scale.

#### Characteristics of the 1883 ignimbrite

The Krakatau pyroclastic flows apparently moved preferentially to the north and north-east and covered the islands and surrounding sea floor with dacitic ignimbrite (Fig. 6). The biased distribution could be due to directed explosions and/or the topographical control of Rakata volcano (813 m) on the collapsing eruption column, forcing material northwards. The only reports of burns caused by hot ash and gases come from the area around Kalimbang in southern Sumatra, 40 km north-east of Krakatau and 25 km in a direct line from temporary islands produced by the pyroclastic flows. The destruction to the north may have been at the outer edge of a directed blast zone, or perhaps due to ash-cloud surges generated off the tops of moving pyroclastic flows. Such ash-cloud surges can apparently move across water as they did in the St Pierre disaster in 1902<sup>18</sup>.

Deposition of ignimbrite extended Sertung and Rakata Kecil Islands and the southern and eastern parts of Rakata (Fig. 6). Shallowing of the sea floor as far as 15 km to the north of Krakatau<sup>3</sup> was caused by submarine pyroclastic flows that

¥.

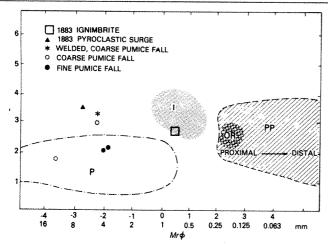

Fig. 5 Grain-size characteristics of Krakatau 1883 pyroclastic deposits, summarized on a plot of median diameter  $Md\phi$  (=  $\phi_{50}$ ) against graphical  $\sigma\phi$  (=  $\sigma_{84} - \sigma_{16}/2$ ), a sorting parameter. The Krakatau pumice-fall deposits are compared with the field of proximal plinian fall deposits (P) and the field of phreatoplinian deposits (PP), after ref. 5. The Krakatau ignimbrite (plot shows area of four analyses) is compared with the field of normal subaerial ignimbrites (layer 2b in ref. 16), (I) and that of ignimbrite produced from a phreatomagmatic eruption, the Oruanui (Or) ignimbrite (S.S., in preparation).

largely filled the 30–40-m deep basin in the sea floor; two new temporary islands, Steers and Calmeyer Islands, were portions of the  $\sim$ 40-m thick ignimbrite exposed above sea level (Fig. 6). Judd (ref. 11, p. 28) erroneously attributed these pumice banks to the growth of parasitic cones on the flanks of the Krakatau volcano.

Yokoyama<sup>2</sup> suggested that these temporary islands were composed primarily of lithic material derived from the explosive removal of the missing portions of Krakatau Island. However, the field descriptions of Verbeek<sup>3,4</sup> and his chromolithographs of these islands<sup>4</sup> clearly show them to be composed of light-coloured pumice and ash similar to the ignimbrite exposed at Krakatau. The >15 km 'run out' distance of the pyroclastic flows was a result of the vast momentum of several km<sup>3</sup> of pyroclastic debris collapsing from a height of perhaps >5 km (ref. 19).

The 1883 magma was a sparsely porphyritic dacite with  $\sim 65-68$  wt % SiO<sub>2</sub>; the small phenocrysts are plagioclase, augite and minor opaques<sup>4,9</sup>. A small amount (< 5 wt %) of grey and white-streaked, mixed pumice is also present.

The ignimbrite is composed of non-welded pumice and ash with  $\sim 5$  wt % lithic fragments (Figs 2 and 4b). A small but significant component (< 5 wt % of the deposit) is non-vesiculated to poorly vesiculated obsidian that we consider to be juvenile. The Krakatau ignimbrite has the typical grain-size characteristics of a sub-aerially erupted ignimbrite (Fig. 5). This contrasts with fine-grained phreatoplinian deposits and associated ignimbrites (S.S., in preparation), which were apparently erupted through water. These ignimbrites are much finer grained than the Krakatau ignimbrite, especially in their lack of large-sized components near source (Fig. 5). This again indicates that magma—seawater interaction did not have a significant role in the fragmentation of the magma during the 1883 Krakatau eruption.

#### Initiation of ignimbrite-forming explosions

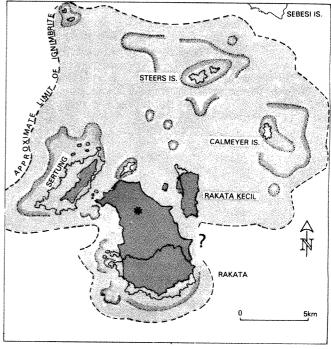

Verbeek<sup>3,4</sup> suggested that the Krakatau eruption became submarine at about 10h on 27 August as a result of foundering of the volcanic edifice, and that the largest explosions were caused by seawater rushing into the vent, making contact with the hot magma and causing it to froth explosively into pumice. By contrast, Judd (in ref. 11) argued that entry of large amounts of seawater into the vent would chill the magma and cause it to crust over. Gas would then accumulate below this crust until explosive pressures were reached. These ideas both assume that

the volcano was collapsing before the explosions. However, the evidence suggests that this was not the case, and that the subsidence at Krakatau and formation of the caldera took place late in the eruption sequence.

First, lithic debris makes up only  $\sim 5\%$  of the deposits which suggests that large-scale collapse of old cone material into the vent was not taking place during the eruption. Second, the coarse-grained nature of both the pumice-fall deposits and the ignimbrite suggests that fragmentation was not caused by magma-seawater interaction. Third, the pyroclastic flow deposits that cover the southeastern part of Rakata Island, and which must have come from one of the vents to the north-west, would be cut off from their apparent source by the caldera wall collapse (Fig. 6). Thus we propose that the large pyroclastic flows were erupted before major collapse of the volcano.

The 1883 caldera lies within the prehistoric Krakatau caldera ( $\sim$ 7 km diameter; Fig. 1), and seems to be a graben-like feature extending along two intersecting zones of fractures<sup>8</sup>. The 'missing' portion of the cone of Rakata may represent a large-scale slump of material into the east-west elongated caldera. The >250-m deep caldera was apparently not extensively filled with deposits of 1883 ignimbrite, also suggesting caldera collapse after the eruption of the major pyroclastic flows and emptying of the magma chamber.

We propose that seawater in large quantities did not gain access to the vent during the most explosive stages of the eruption but that seawater may have leaked slowly into the conduit area, sparking small phreatomagmatic explosions. Such explosions would have broken a cap of viscous magma and allowed sudden, explosive release of large batches of vesiculated magma from beneath the upper conduit system (see refs 20-22). Contemporary accounts indicate that the explosive activity subsided in the early hours of 27 August before the large explosions started (Fig. 3). This may have allowed a partly solidified plug to develop in the vent, facilitating the above

PRE-1883 ISLAND OUTLINE

Stippled pattern shows extent of ignimbrite. Also shown are temporary islands and shallow banks where ignimbrite protruded above sea level (outline of islands after ref. 11).

mechanism. The presence of juvenile obsidian clasts in the ignimbrite might indicate partly solidified magma in the vent.

It has been suggested that some large volcanic explosions can be triggered by magma mixing<sup>23,24</sup>. Sudden mixing of rhyolitic and basaltic or andesitic magma might lead to violent exsolution of dissolved volatiles. A small percentage (<5%) of grey and white-streaked pumice occurs in the Krakatau ignimbrite, suggesting some mixing of magmas. However, we cannot envision a magma-mixing process that would adequately explain the sequence and timing of the large explosions of Krakatau as alluded to by Rice<sup>25</sup>. Magma mixing may have had a role in initiating the eruption, but we do not believe that mixing events were the prime cause of the major explosions on 27 August.

#### Co-ignimbrite ash

During the eruption of the pyroclastic flows, much vitric dust was dispersed in the atmosphere and formed a widespread thin, fine ash-fall deposit<sup>4</sup>. Considerable distal ash fall did not occur until the large explosions of 27 August, and we suggest that the widespread ash fall was mainly co-ignimbrite ash<sup>26</sup>.

Mechanisms envisaged for the generation of the high-altitude column of fine vitric dust and gases that accompanies many events involving production of pyroclastic flows are: (1) rise of selectively fine (low terminal fall velocity) material above the vent; (2) generation of ash from the moving pyroclastic flows; and (3) secondary explosions that may occur as hot pyroclastic flows enter the sea<sup>6</sup>. Evidence for this type of secondary explosion was not found at Krakatau, possibly because of the lack of lateral exposure. However, the expected airfall layers produced by such secondary explosions are not present between the ignimbrite flow units at Krakatau in the outcrops we examined.

All large ignimbrite eruptions are accompanied by the production of co-ignimbrite ash<sup>26</sup>. This fine ash consists of the vitric component—pumice shards and fragmented shards commonly from 50 µm down to a few µm in diameter. The finest ash was capable of significant stratospheric residence times varying from days to months (depending on size). This dust may have been partly responsible for the widespread atmospheric optical phenomena observed after the August 1883 eruption (refs 27, 28, Russell and Archibald in ref. 11), although the sulphate aerosols generated by the eruption were probably more important<sup>29</sup>.

#### Volume of the 1883 eruption

Calculations of the total volume of ejecta from the 1883 eruption must include the volume of widely dispersed dust and ash as well as the subaqueous ignimbrite. Volumetric estimates range widely from Verbeek's  $18 \text{ km}^3$  for the total ejecta<sup>3,4</sup>, to the Royal Society's value of  $14.4 \text{ km}^3$  for the fine distal ash fall alone<sup>11</sup>, to recent estimates of  $13 \pm 4 \text{ km}^3$  (ref. 2) and only  $5 \text{ km}^3$  (ref. 30) for the total ejecta based on the volume of the caldera.

Close to Krakatau, Verbeek4 estimated from field investigations and depth soundings of the sea bottom before and after the eruption that 12 km<sup>3</sup> (bulk volume) was ejected. This is a reasonable figure for the volume of ignimbrite produced, based on a sheet of ignimbrite averaging ~ 40 m thick and covering an area of  $\sim 300 \text{ km}^2$  (Fig. 6). Verbeek also considered the volume of widely dispersed ash and estimated this to be 6 km<sup>3</sup>. This value must be a minimum because it only considers a portion of the total dispersal area, which the Krakatoa Committee estimated to be  $1.1 \times 10^6$  miles<sup>2</sup> (see ref. 11, p. 448). Our recalculation of the volume of widely dispersed ash from data in ref. 4, using an area against thickness plot and extrapolating to 1 mm thickness<sup>31</sup>, gives 8.5 km<sup>3</sup>. Recent studies of co-ignimbrite ash volumes compared with the volume of the parent ignimbrite indicate that up to 50% of the magma erupted can be co-ignimbrite ash<sup>26,32</sup>. Applying the methods for estimating crystal concentration in ignimbrites<sup>26,33</sup>, preliminary studies suggest that the Krakatau ignimbrite must have lost at least 40% of the vitric component into the fine co-ignimbrite ash, which therefore has a minimum volume of  $\sim 5~\text{km}^3$ . The above calculations suggest a bulk volume of fine, dispersed ash between  $\sim 5~\text{km}^3$  and  $8.5~\text{km}^3$ .

The pre-27 August sub-plinian fall and surge deposits are thought to be of small volume, probably  $<1~\rm km^3$ . Analysis of samples suggests that only 8% of fine vitric material in these deposits is missing. Therefore, the volume of fine ash produced during the sub-plinian phase of the eruption is very small compared with that emitted during the ignimbrite-forming phase. When the amounts of ignimbrite, co-ignimbrite ash and sub-plinian deposits are added up, the total bulk volume of the 1883 Krakatau deposits is  $18-21~\rm km^3$ . The equivalent volume of dense rock may be roughly estimated as  $9-10~\rm km^3$ .

#### Generation of tsunami

The Krakatau eruption also produced tsunami that inundated coastal areas around the Sunda Straits. These tsunami are generally attributed to submarine explosions or to caldera collapse<sup>8,34</sup> although ejecta falling into the sea has also been suggested<sup>3,4,11</sup>. The evidence indicates that the tsunami were caused by several cubic kilometres of pyroclastic flow material entering into the sea immediately after each of the large explosions.

The early small explosions of 26 August were followed by small tsunami (Fig. 3). For example, an explosion occurred at about 17h 20min on 26 August, and the first destructive waves reached the Java and Sumatra shores 40 km from Krakatau soon afterwards, between 18h and 19h. This early wave or waves may have been due to surges or small pyroclastic flows entering the sea. No other destructive waves were observed until the morning of 27 August (Wharton, in ref. 11). At about 6h 30min a large wave swept over much of the Java coast; another wave followed at about 7h 30min. At about the same time a wave hit low-lying areas of Sumatra. These waves followed the large explosions at 5h 30min and 6h 44min (Fig. 3).

At some time after 10h a gigantic wave (or waves) inundated the coasts bordering the Sunda Straits. This wave is reported to have been the largest, and was the last recorded in the straits; most survivors of the earlier waves had by this time fled from the coastal areas. The tide gauge at Batavia (Jakarta) also recorded waves that correspond to the large explosions.

The sequence and timing of tsunami suggest that the major tsunami were generated at the times of the explosions (Wharton, in ref. 11). Pyroclastic flows resulting from column collapse would have entered the sea within about  $\sim 30 \, \mathrm{s}$  of the explosions  $^{19}$  and initiated the tsunami. The slumping of large parts of the volcano, for example the segment of Rakata cone that probably slid into the caldera, could have been a factor in generating tsunami late in the eruption.

The idea that tsunami can be caused by pyroclastic flows entering the sea is supported by a study of the huge eruption of Tambora in 1815 during which tsunami were generated which flooded the nearby coasts of Sumbawa to a height of 4 m, and Java to a height of 2 m (ref. 33). These waves could not have been produced by magma-seawater interactions or caldera collapse, as the volcanic crater lies some 15-20 km inland at an elevation of about 2,850 m. Pyroclastic-flow deposits from the 1815 eruption entered the sea at the base of the volcano (M.R.R. and S.S., in preparation), and this was the most likely cause. The large tsunami that are inferred to have accompanied the Minoan eruption of Santorini<sup>34</sup> may have been generated in the same way.

We conclude that the 1883 eruption was an ignimbrite-forming event of modest volume. The deposits are largely coarse-grained non-welded dacitic ignimbrite and show little support for a phreatomagmatic origin. The occurrence of welded pumice-fall deposits beneath the ignimbrite also seems to argue against water-magma interaction in the early stages of the eruption. The presence of mixed pumice clasts indicates some magma mixing and supports the contention that welded airfall deposits result, in some cases, from superheating of

magma during a mixing event<sup>15</sup>.

During the paroxysmal phase, four or five large-volume explosions driven by magmatic gases led to collapse of the eruption column, and to the production of pyroclastic flows that entered the sea. The blasts and ensuing pyroclastic flows seem to have been directed preferentially towards the north and northeast. The times of the explosions correlate with the times of tsunami generation, and we propose that the entry of the pyroclastic flows into the sea caused the major tsunami. Caldera collapse probably came late in the eruption.

The total volume of the deposits of the Krakatau eruption is estimated to be 18-21 km<sup>3</sup> (bulk volume), including 12 km<sup>3</sup> of

# **Evaluation of the Seasat wind scatterometer**

W. L. Jones, D. H. Boggs, E. M. Bracalente, R. A. Brown, T. H. Guymer, D. Shelton<sup>†</sup> & L. C. Schroeder<sup>\*</sup>

> \* NASA Langley Research Center, Hampton, Virginia 23665, USA † Jet Propulsion Laboratory, Pasadena, California 91103, USA ‡ University of Washington, Seattle, Washington 98195, USA § Institute of Oceanographic Sciences, Wormley, Surrey GU8 5UB, UK

Surface wind velocities have been derived from backscatter measurements of the ocean surface made by a satellite-borne, microwave sensor. Comparisons with high-quality surface-based measurements obtained during the Joint Air-Sea Interaction experiment are described. The accuracy of the scatterometer winds at this mid-latitude site,  $\pm 1.6$  m s<sup>-1</sup> in speed and  $\pm 18^{\circ}$  in direction, for winds between 3 and 16 m s<sup>-1</sup> is within the design specification.

THE Seasat-A Satellite Scatterometer (SASS) was one of several microwave remote sensors onboard the first oceanographic satellite<sup>1</sup>, Seasat-A, and provided wind velocity estimates over the world's oceans from a height of 800 km. The technique is based on the sensitivity of microwave radar backscatter to the amplitude of short gravity waves (few centimetres) created on the sea-surface by the action of the wind. The sensor and the algorithms used to convert radar backscatter into winds are detailed elsewhere<sup>2-5</sup>

Design specifications for the SASS required a wind speed measurement range of  $4-26 \text{ m s}^{-1}$  with an accuracy of  $\pm 2 \text{ m s}^{-1}$ or 10% (whichever is the greater) and a wind direction range of  $0-360^{\circ}$  with an accuracy of  $\pm 20^{\circ}$ . To check whether these criteria are satisfied the inferred wind vectors must be compared with those obtained by surface instrumentation. Because the accuracy and coverage of routine wind reports at sea are generally not high enough to evaluate the scatterometer measurements properly, a special series of measurements from ships and buoys was conducted in the Gulf of Alaska<sup>6</sup>. It was also fortunate that the field phase of the Joint Air-Sea Interaction (JASIN) experiment took place during the lifetime of Seasat. One of its aims was to provide accurate estimates of the surface meteorological fields over a 200 × 200 km area, and, as a result of careful intercalibrations, high-quality surface wind data are therefore available. This article describes the results of comparisons made at the Seasat-JASIN workshop<sup>8</sup> and demonstrates that the specifications for the SASS have been met for wind speeds up to 16 m s<sup>-1</sup>.

#### Seasat scatterometer

The strength of the radar backscatter (normalized radar crosssection  $\sigma^{\circ}$ ) is a function of the amplitude of very short gravity waves which is itself proportional to the near-surface wind speed. Further, the radar backscatter is anisotropic, so that wind direction can be derived from scatterometer measurements at different azimuths.

The SASS was designed to view the ocean at two azimuths, as shown in Fig. 1. Four dual-polarized, fan-beam antennas were aligned such that they pointed  $\pm 45^{\circ}$  and  $\pm 135^{\circ}$  in azimuth relative to the subsatellite track to produce an X-shaped pattern of illumination on the Earth. In this way, a given surface location was viewed first by the forward antenna and then  $\sim 1-3$  min later (depending on whether the location was at the inner or outer portion of the swath) it was viewed orthogonally by the aft beam. Twelve Doppler filters were used to subdivide the antenna footprint electronically into resolution cells ~15 km (across beam) ×70 km (along beam). In the results presented here pairs of cells were selected having separations <37 km. It is assumed that during the interval between samples the short gravity-wave field integrated over such areas remains constant. The incidence

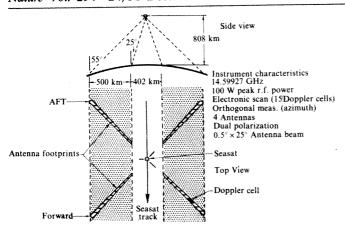

Fig. 1 The swath geometry of the Seasat Scatterometer: viewed from the side (upper) and from the top (lower).

angles of the cells ranged from 25° to 55° for the region of forward and aft beam overlap. Three additional measurements from incidence angles near nadir covered the subtrack, although no directional information can be obtained in this case.

The SASS geophysical algorithm<sup>3</sup> enables wind speed and direction at the sea surface to be computed from  $\sigma^{\circ}$  measurements after correction for attenuation through the atmosphere. This arises principally from water vapour, the vertical integral of which was estimated using data collected by a microwave radiometer on the same satellite<sup>9</sup>.

The model function  $F(W, \chi)$  is the empirical relationship used to describe the dependence of the ocean  $\sigma^{\circ}$  on the wind vector

$$F(W, \chi) = G(\theta_i, \phi, \varepsilon) + H(\theta_i, \phi, \varepsilon) \log W$$

where  $\theta_i$  is the incidence angle,  $\phi$  is the azimuth angle between the wind direction and the radar look angle,  $\varepsilon$  is the polarization of the beam and W,  $\chi$  are the wind speed and direction. Several model functions have been used in the past having different values of G and H for the various combinations of  $\theta_i$ ,  $\phi$  and  $\varepsilon$ . The coefficients were obtained from near-simultaneous measurements of  $\sigma^{\circ}$  and surface wind speed and direction. An airborne scatterometer<sup>10,11</sup> provided 3,000  $\sigma^{\circ}$  values and 2,000 more resulted from SASS during GOASEX6. A least-squares method is used to find values of W and  $\chi$  that, for a given model function, will produce the best fit to the  $\sigma^{\circ}$  observations. Two to four wind vectors result which are approximately equal in magnitude but are widely separated in direction. These multiple local minima (alíases) are due to the harmonic dependence of  $\sigma^{c}$ on wind direction. The solutions are not random and it has been shown<sup>12</sup> that synoptic meteorologists can, using SASS data alone, select the direction closest to the observed wind on a high proportion of occasions. At the time of the Seasat-JASIN workshop the SASS data still contained the aliases so statistics were computed using the solution which gave closest agreement with observations.

Before the workshop, two model functions (W-7 and CWK)

had been developed using the aircraft and GOASEX data sets and were used to generate two sets of SASS wind data for 23 overpasses, chosen to give good spatial coverage of the JASIN area and as wide a range of wind speeds as possible. The JASIN surface data were withheld from algorithm developers and thereby provided the first independent assessment of the scatterometer's wind-measuring capabilities.

#### The JASIN experiment

During JASIN, 14 ships, 3 aircraft and 35 surface and subsurface moorings were deployed in an area 200 km off north-west Scotland during July to September 1978 and several of these platforms were equipped with wind-measuring devices. Three ships, stationed at the vertices of a 200-km triangle, reported winds every hour with a fourth ship at the centre for some of the time. Two other roving ships and several buoys near two of the corners carried data logging systems. Careful intercomparisons were made between the ships and buoys to produce an internally-consistent data set in which interplatform differences in winds are <0.5 m s<sup>-1</sup> and 5°. The absolute accuracy of the winds is difficult to ascertain but both wind-tunnel calibrations and momentum flux comparisons with aircraft suggest that this error is 2 or 3%.

Wind speeds experienced during the 23 Seasat overpasses ranged from 0 to 16 m s<sup>-1</sup> with 83% distributed between 6 and 14 m s<sup>-1</sup>. Measurements were made at heights from 2.5 to 23 m above the surface and in different atmospheric stabilities. In this layer there is considerable variation of speed with height due to friction (direction being constant) so all measurements were corrected to give the 19.5-m neutral stability wind. This is the wind speed that would result at 19.5 m from a given surface stress if the atmosphere were neutrally stratified with an adiabatic lapse rate. The SASS algorithm also outputs the 19.5-m neutral stability wind as it has no means of estimating the stability.

# Comparison of SASS winds with surface-based data

First, SASS winds were compared with autologged data from ships and buoys within the JASIN triangle. The latter provided

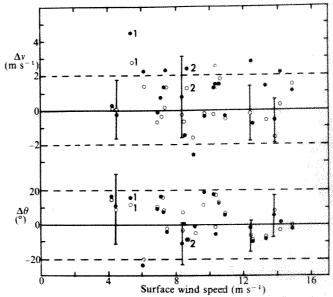

Fig. 2 SASS wind minus surface wind (speed  $\Delta v$  and direction  $\Delta \theta$ ) as a function of surface wind speed. The surface winds are 60-min averages of logged data centred on the time of the satellite pass. All winds have been corrected to 19.5 m. Each point represents the mean difference for all comparisons on a particular overpass (total of 1,150 on the 23 passes). W-7 model; O, CWK. In both cases vertical and horizontal polarizations have been combined. Selected standard deviations are shown for clarity; two cases had much higher standard deviations (>3.5 m s<sup>-1</sup>) and are annotated.

time series of 1-15-min means which were combined to form 60-min means centred on the time at which the satellite pass occurred. This procedure is an attempt to obtain winds which are consistent with the areal average of the SASS. Figure 2 shows differences between SASS and surface winds for both model functions expressed as a function of wind speed. Most of the points lie within the design specifications. The two numbered points refer to different occasions when the differences exhibited large scatter. The more obvious was Case 1 with a mean difference of 4.5 m s<sup>-1</sup> and a standard deviation of 4.7 m s<sup>-1</sup>. For this case, very high SASS winds were indicated having values up to 22 m s<sup>-1</sup> in a 4-5 m s<sup>-1</sup> field. The anomaly was localized and from ship reports and data from the microwave radiometer subsequently identified with a thunderstorm<sup>13</sup>. For Case 2 the surface data revealed that the comparisons were made in an area of horizontal wind gradient ahead of a cold front, which accounts for much of the observed differences, the SASS footprints being some distance from surface platforms.

It is reasonable to assume that in all cases some of the scatter is due to real spatial variability in the winds which is not satisfactorily removed by time-averaging the surface data. An attempt to smooth such effects out was made by constructing wind fields showing isotachs and streamlines based not only on

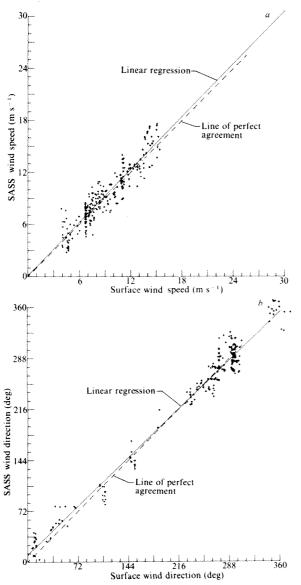

Fig. 3 Scatter plot of: a, SASS wind speed versus surface wind speed for CWK model; b, SASS wind direction versus surface wind direction. The surface data are taken from smoothed fields based on autologged data and manual observations. Slopes: 1.0195 (a); 0.9564 (b). Intercepts: 0.1094 (a); 10.0360 (b). Correlation coefficients: 0.9200 (a); 0.9872 (b).

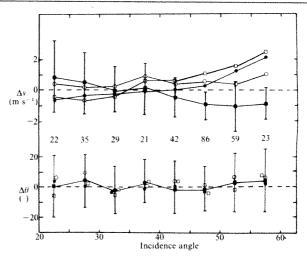

Fig. 4 Comparison of SASS with surface winds derived from plotted fields for various ranges of incidence angle. Horizontal and vertical polarizations for the two model functions are shown. For the CWK, H-pol case the standard deviation of the individual comparisons is also shown together with the number of measurements in each category. Those for the other cases are similar ■, CWK, H-pol; ○, CWK, V-pol; ●, W-7, H-pol; □, W-7, V-pol.

the autologged data but on hourly manual observations from the corner ships to increase the spatial coverage. Values of winds were interpolated at  $0.5^{\circ}$  latitude and longitude grid points and were available for colocation with SASS data points. A crosscheck of these data with the *in situ* observations discussed previously showed agreement to  $\pm 0.6$  m s<sup>-1</sup> and  $\pm 4^{\circ}$ .

Statistics were again calculated using the solution with wind direction closest to the observed value. Scatter diagrams of SASS wind speed and direction (CWK model only) versus surface measurements are shown in Fig. 3 and their dependence on incidence angle and polarization is shown for both W-7 and CWK model functions in Fig. 4. For several categories the standard deviation slightly exceeds the design specification; however, note that for these cases the statistical uncertainty is large because of the limited sample size. These figures illustrate the differences between SASS and JASIN smoothed winds, only a small part of which can be attributed to errors in the JASIN data.

#### **Conclusions**

One objective of the Seasat–JASIN workshop was to demonstrate that winds near the sea surface could be inferred to an accuracy of  $\pm 2~{\rm m~s^{-1}}$  in speed and  $\pm 20^{\circ}$  in direction by means of SASS without prior knowledge of the surface data. In wind speeds up to  $16~{\rm m~s^{-1}}$  the SASS wind vector algorithm recovers wind speed to an accuracy of  $\pm 1.6~{\rm m~s^{-1}}$  for W-7,  $\pm 1.4~{\rm m~s^{-1}}$  for CWK and wind direction to an accuracy of  $\pm 18^{\circ}$  for both model functions (see summary in Table 1). Differences between the two are small and are most noticeable in the dependence of SASS wind speed on incidence angle. The worst cases occur with incidence angles below 25° and above 55° as also found by Halberstam in a comparison with the combined GOASEX/JASIN surface data sets.

In this study the surface data were far superior in accuracy and sampling to data provided by the routine meteorological network. They were also of higher quality than data from GOASEX in that careful analysis of the many intercomparisons between JASIN platforms resulted in reduction of the biases which were present. This in turn has reduced the scatter in comparisons with SASS<sup>15,16</sup>. The scatterometer data are now being used in combination with the JASIN data to increase our understanding of how the atmosphere and ocean interact on a variety of time and space scales.

We thank the JASIN investigators for initial versions of the surface meteorological data.

\*\* Department of Geology, National Museum of Wales, Cardiff CF1 3NP, UK

An Acheulian industry in association with a hominid molar has been found at Pontnewydd Cave. This tooth represents the oldest hominid specimen known from Wales and, except for the Swanscombe fossil, from Britain. The molar is probably from a young adult and the tooth closely resembles those of 'Early Neanderthal' fossils from Krapina, Yugoslavia, a comparison accentuated by the degree of taurodontism at both sites. Uranium-thorium and thermoluminescent dates suggest an age for the specimen of around 200 kyr. Uranium relative dating indicates a Pleistocene age for two additional unstratified hominid fragments. Sedimentological study of the deposits and examination of the rock types in the cave, both natural and artefactual, indicates earlier glacial activity.

PONTNEWYDD CAVE has been the subject of four seasons of excavation (directed by H. S. Green for the National Museum of Wales). Excavation of the cave in the 1870s by Boyd Dawkins 1.2 and by McKenny Hughes<sup>3,4</sup> produced fauna, including a possible human tooth, since lost, and artefacts which were compared with finds from Le Moustier and St Acheul. No further work took place at the cave until the present excavation except for construction work at its mouth during the Second World War, when the cave was converted to a store.

#### Location and geomorphological setting

The cave is situated in the lower Elwy valley of North Wales (Fig. 1), the entrance opening off the Carboniferous Limestone scarp that forms one side of the valley. The cave entrance is at a height of 89.5 m OD, exactly 50 m above the river Elwy. The valley contains thick deposits of drift, in places built into a series of terraces whose upper surface locally approximates to the height of the cave. The data from the cave should elucidate the Quaternary geology and geomorphology of the area for which. hitherto, there has been no reliable chronological framework in which to place the Quaternary sequence. Moreover, as the cave is situated close to the probable maximum limit of penetration of Irish Sea Ice into the area, it may provide a means of dating the advances of this ice sheet as well as those of the more local Welsh Ice.

#### Stratigraphy

Sedimentological studies were originally aimed to correlate the sequence of the three separate areas of the cave in which substantial deposits survive intact (Fig. 2a: South Fissure and adjacent Deep Sounding; South Passage; and East Passage). High probability correlation, based on lithologic characters, has resulted in the composite stratigraphy shown in Fig. 2b. Interpretation has proceeded using data derived from both standard sedimentological analyses and the study of microtextural assemblages of quartzitic particles by scanning electron microscopy (SEM).

The lowest stratigraphical unit, the Basal Sands and Gravels, consists of a complicated series of deposits containing matrixsupported, well rounded siliceous particles, frequently 100-150 mm in diameter. These pebbles are often crudely oriented in field exposures, suggesting en masse movement. Discrete lenses of generally matrix-poor, finer-grained material (coarse sands and fine gravels) are common throughout the deposits, both vertically and laterally, as are lenses of laminated clayey silts. Conditions of periodic streamflow, ponding and gentle slumping, as a result of mudflow processes, are indicated. SEM examination suggests that the silt and sand-sized material from all these deposits originates from a mixed provenance and an equally mixed range of environments of modification. The sands are probably derived from local tills and fluvial sediments, introduced into the cave after a greater or lesser mixing of the original sources.

The Intermediate Complex comprises a group of deposits that are lithologically transitional between the Basal Sands and Gravels below and the Breccias (infra) above. In general terms, the Complex may be characterized by the presence of siliceous pebbles, badly sorted coarse sand and highly altered limestone clasts. Internal stratigraphical relationships between different areas are unclear, due to the discontinuous nature of individual

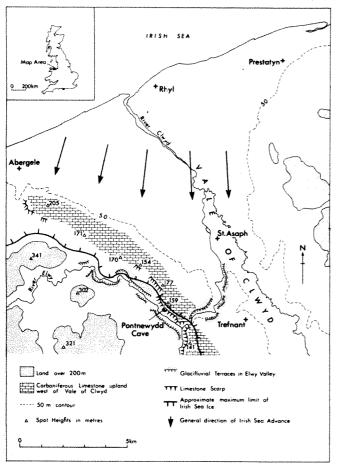

Fig. 1 Pontnewydd Cave. Location and geomorphological setting.

lenses and extreme lateral variability. Some occurrences show the combined effect of syngenetic growth of carbonate concretions and input of large quantities of organic matter. Microscopically, the grain textural suite combines qualities of both the underlying and overlying deposits, although the grain surface textural modification is basically fluvial in origin. Nowhere are primary fluvial deposits clearly evidenced; the matrix-supported fabric and poor sorting indicate that mass movement was again the last major emplacement process involved.

The two units of the Breccias comprise many angular coarse particles, mainly limestone, with medium to strong carbonate cement. Compared with the Lower Breccia, the Upper Breccia contains much more silt and fine sand, fewer but more severely fractured siliceous pebbles, and abundant but considerably less altered limestone clasts. The units are separated by stalagmite growth and laminated silts in some places. Under SEM, the Breccias are distinctly different from the Basal Sands and Gravels, although they show similar intra-sample variation. There are either provenance variations or process modification differences, or both, between the two Breccias. Whilst both contain mainly mechanically crushed quartz grains, surface modification, of only limited extent in both cases, is primarily fluvial in the Lower Breccia but both fluvial and diagenetic in the Upper Breccia. These deposits are the result of mudflow on a major scale, originating from the direction of the cave entrance. This process was interrupted once, during a period of relative quiescence, by limited fluvial (local drainage) and pool sedimentation, together with the growth of stalagmites, in what was probably a closed cave environment. The Breccias incorporate reworked material from the underlying deposits and, at one point, the Upper Breccia has clearly channelled the Lower Breccia and Intermediate Complex; this is consistent with the mode of emplacement envisaged. The limestone component and some of the silts and fine sand result from repeated inputs of entrance facies sediments. Alteration and cementation of the Breccias occurred before the entry of the next deposit.

There are no recognizable stable surfaces within the Breccias or the Intermediate Complex. Artefacts and fauna, which occur throughout the former and in certain deposits of the latter, would have been subject to transport and reworking like any other particle during mass movement.

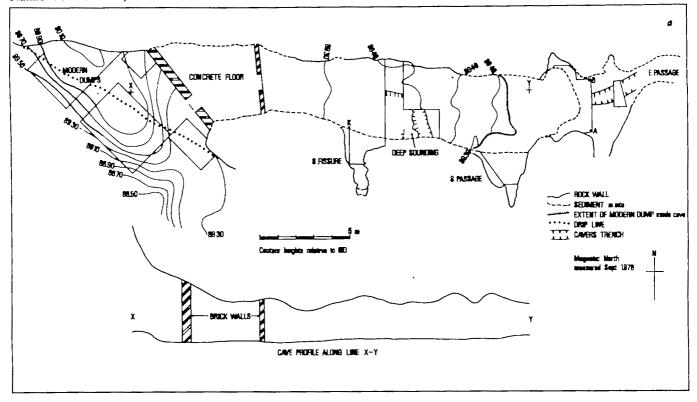

In the South Fissure only, the Breccias are overlain by a small remnant of uncemented, silty Red Cave—Earth, with abundant angular limestone clasts. These clasts lack all signs of chemical alteration but are slightly edge-rounded, indicating derivation from unweathered entrance facies sediments by mass movement. The quartz grains are texturally different from those of the Breccias but further analysis is necessary before any interpretation can be made.

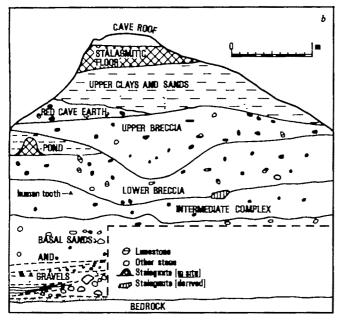

A series of current-bedded clays and sands is present in all areas, overlying either the Red Cave-Earth or the Breccias and is the result of an effluent stream that is clearing a choked drainage system. This unit (the upper clay and sands) is followed conformably by a thick stalagmitic floor.

#### Chronology

(1) Uranium series dating-The principles involved in the dating of travertines from cave-sites are described elsewhere<sup>5</sup>. The stratigraphical contexts of the dated samples from the South and East Passages and their locations in the cave are given in Fig. 3. Four of the samples were probably in situ. Of these D188 yielded a maximum age of 20 kyr, suggesting a late Devensian or Holocene age for the stalagmitic floor which caps the sequence; CO and D604 are important as, in combination, they yield a minimum age of 170 kyr for the emplacement of the Lower Breccia in which the bulk of the archaeological finds is contained. The determination of 180 ± 20 kyr (D471), on derived stalagmite from the Lower Breccia, is consistent with this minimum age. Two dates centred on 90 kyr from a small stalagmitic boss probably in situ on the Lower Breccia (D312) suggest a long period of quiescence before the incoming of the Upper Breccia, and a further date of 125±6 kyr (D187), equivalent to Oxygen Isotope Stage 5e (ref. 6), on a stalactite incorporated into the Upper Breccia seems to confirm this and suggests that the solifluction of this layer occurred at a later cold stage. We believe that the cave had been sealed in the entrance area by the Lower Breccia deposit and so remained until this plug was breached during downcutting (through drift) of the

Elwy Valley<sup>7</sup>, resulting in the emplacement of the Upper Breccia deposit. This view is supported by oxygen isotope analysis of single growth layers of stalagmite D312 which show it to have been deposited in equilibrium with its feed waters, a characteristic of deposits found in sealed caves<sup>8</sup>.

(2) Uranium relative dating—Ten bones including one modern dog femur, seven bear bones representative of the different levels in the cave, and the human mandible and vertebra were submitted for relative dating. Post-depositional uptake of uranium series elements was assessed by counting  $\beta$ -particle emissions. All the bones, except the modern dog, gave counts higher than background, and it can be inferred that they, including the two human bones, are of some antiquity. The bones from the Upper and Lower Breccias, however, could not be distinguished, suggesting that they are not of greatly differing ages.

(3) Thermoluminescence dating-The ages obtained for emplacement of the Lower Breccia directly date neither the contained 'industry' nor the fauna beyond giving a minimum age of 177 kyr. We are fortunate in that a thermoluminescence (TL) date has been obtained from a globular burnt flint core from the Intermediate Complex immediately below the base of the Lower Breccia in the East Passage. The TL date is significant not only because it probably dates the use of fire on the site, almost certainly to be associated with the human occupation, but also because the hominid tooth described below was discovered within the same layer and in close proximity to it (Fig. 3). The date obtained is 200 ± 25 kyr (OXTL 226d1). The burnt flint core (D687) has been dated using the method previously described for flint10. TL parameters are as follows: Archaeological dose  $(29.6\pm1.0)$  krad for 1–8  $\mu m$  grains;  $(28.7\pm1.0)$  krad for 90–150  $\mu m$  grains; a value 10.085; plateau region 375– 475 °C; internal dose 0.025 rad yr<sup>-1</sup>. Soil  $\gamma$  + cosmic dose: 0.120 rad yr<sup>-1</sup> derived from fluorite dosimeter measurements in the layer. (Cosmic ray dose 0.003 rad yr<sup>-1</sup>, on site y spectrometer measurement.) Excavation water content 0.8 of saturation, which was 25% expressed as a percentage of dry weight. Assumed soil water content over the burial period  $(0.7 \pm 0.3)$  of saturation. Subsidiary measurements for Lower Breccia, Intermediate and immediately underlying Basal Sands and Gravels indicate radioactive homogeneity. TL age (200± 25) kyr: lab. ref. no. OXTL 226d1. The error quoted is the total predicted error at the 68% confidence level calculated as previously described12,13

#### **Hominid** finds

Of the three hominid finds, one, a tooth (Pontnewydd 1) whose stratigraphical position is indicated in Fig. 2b, is described below. The others, an immature mandible fragment (PN 2) and a vertebra (PN 3), are both from unstratified contexts but uranium relative dating indicates no difference in age between these specimens and the remainder of the Pleistocene fauna.

The human tooth from Pontnewydd is a left upper molar, probably an  $M^2$  of an adult individual. It has a large and low

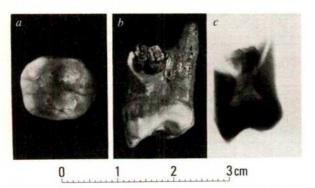

Fig. 4 The human molar: a, occlusal view (distal side at bottom); b, distal view; and c, radiograph of distal view.

25mm

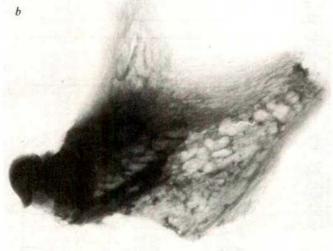

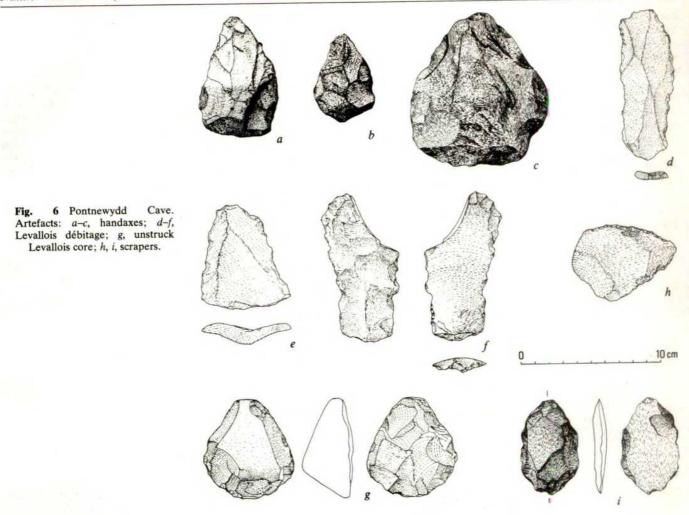

Fig. 5 The mandibular fragment: a, medial view; b, medial radiograph.

rectangular crown and a complete lingual root, but the buccal roots are broken (Fig. 4a, b).

The molar has four cusps. The protocone is the largest, the paracone is slightly larger and higher than the metacone, while the hypocone is small. The buccal cusps are higher than the lingual cusps and initial dentine exposure is apparent on the protocone. An oblique crest joins the protocone and metacone, and there are only moderately marked buccal and distal grooves. The lingual crown surface is more convex than the buccal surface, but there is no Carabelli's pit or cusp on the lingual surface, nor is a cingulum present. There are clear interstitial contact facets on both mesial and distal surfaces. The buccal roots are still fused at the point where they are broken, and taurodontism (enlargement of the pulp cavity) is associated with coalescence of the roots over half the length of the lingual root<sup>14</sup>. When intact the roots apparently barely diverged from each other, but they show a slight distal inclination.

Radiographs (Fig. 4c) of the molar show marked enlargement of the pulp cavity into the roots, which assume a prismatic shape. The form of the pulp cavity corresponds to Kallay's category of 'radicular endotaurodontism'<sup>15</sup>, where the cavity displays an hour-glass shape. This form of taurodontism is present in  $\sim 40\%$  of permanent molars examined from the last interglacial–early

last glaciation site of Krapina, Yugoslavia<sup>15,16</sup>. The Krapina sample displays the highest reported frequency and degree of such taurodontism, but taurodontism is not confined to Neanderthal fossils, nor is it characteristic of them in general. Comparative data on the distribution of this character are lacking for many middle Pleistocene hominids, although the Choukoutien and Mauer dentitions show a moderate degree of taurodontism<sup>17</sup>. On the other hand, the Bourgeois–Delaunay molars, stratified both in and immediately below a stalagmitic floor attributable to a temperature phase on pollen analytical grounds but dated by the U–Th method to  $146\pm16$  kyr, are reported to show none<sup>18,19</sup>. Therefore the Pontnewydd molar may represent one of the earliest known examples of this degree of taurodontism in the fossil hominid record.

Table 1 lists measurements for the Pontnewydd molar and a comparative set of measurements on the M2 of a Homo erectus sample, and of selected European middle and upper Pleistocene hominids. The crown dimensions and crude crown area of the Pontnewydd molar are close to the mean values of the Homo erectus and Krapina Neanderthal samples. The crown dimensions of the tooth also fall well within the size range of a last glaciation European Neanderthal sample, and within the upper limit of the range of an early Upper Palaeolithic sample. However, the molar is smaller than those of the middle Pleistocene sample (Petralona 1 (ref. 20), Arago 21 and the Bilzingsleben M<sup>1</sup> or M<sup>2</sup> (ref. 21)), while probably larger than that of the Steinheim specimen (comparative data on original not available). The Pontnewydd molar is identical in breadth to the mean value of a last glaciation Neanderthal sample, but is longer than most such specimens. Data on root dimensions are unavailable for many fossil hominids, but comparisons with Weidenreich's data (Table 1) suggest that the Pontnewydd molar has long and robust roots.

If the molar is an M<sup>2</sup>, then the complete root indicates an individual of at least adolescent age. Furthermore the presence of a distal interstitial wear facet suggests that M<sup>3</sup> was also in occlusion. However, the moderate degree of occlusal wear on the Pontnewydd molar suggests that this tooth derived from a young adult individual.

Some preliminary comments can be made about the immature mandibular fragment (PN2) and the vertebral fragment (PN3). The mandibular fragment represents part of the right ascending ramus, together with the crown of a molar, without developed roots (Fig. 5a). The ascending ramus lacks the upper parts of the coronoid and condylar processes and the lower border, and its minimum breadth is 31.5 mm. Exact identification of the molar is difficult, but it is small (mesio-distal length 11.2 mm; buccolingual breadth 10.5 mm; crude crown area 117.6 mm2) and has a simple five-cusped pattern. From the condition of the molar and the fact that radiography (Fig. 5b) shows the absence (presumed developmental) of a more posterior molar, three possible ages for the individual could be proposed, based on modern developmental patterns, assuming the preserved molar is an (1) M1, (2) M2, (3) M3, respectively. The first possibility, implying an age of <3 yr, can be excluded by the size of the ascending ramus. The second possibility, implying an age of 8-9 yr, would enable the size of the ascending ramus to be matched with those of earlier upper Pleistocene hominids such as Teshik-Tash 1 and Irhoud 3, which are at broadly comparable developmental stages22. In this case the relatively large ascending ramus would favour its identification as a non-anatomically modern specimen. The third possibility would imply a developmental age of >11 yr; the ascending ramus dimensions would then favour the identification of an anatomically modern, rather than archaic, morphology. However, whether the molar is an M2 or M3, its simple crown morphology, without the accessory cusps so often found in middle and earlier upper Pleistocene specimens, and its small size (near or below the minimum values for length and area in the large Krapina sample<sup>23</sup>) suggest caution about identifying the mandibular fragment as Middle Pleistocene in age.

The vertebral fragment represents the posterior and inferior parts of the body of a middle thoracic vertebra, probably from an adult individual. Two costal facets are preserved on the inferior part of the body, but the fragmentary nature of the specimen and its unremarkable morphology preclude further comment.

#### Pleistocene mammals

Faunal remains occur in three successive lithological units, the Intermediate Complex and the Lower and Upper Breccias. The following list includes the mammals from the Lower Breccia and Intermediate Complex of the East Passage only.

Ochotona pusilla: Pika Lepus cf. timidus: Hare Castor fiber: Beaver

Lemmus lemmus: European lemming Ar vicola terrestris: Water vole Microtus oeconomus: Northern vole Microtus gregalis: Tundra vole Apodemus sp.: Mouse Vulpes vulpes: Fox Ursus sp.: Bear Panthera leo: Lion

cf. Panthera sp.: Leopard-sized cat

Equus sp.: Horse

Dicerorhinus kirchbergensis: Rhinoceros

Cervus elaphus: Red deer Rangifer tarandus: Reindeer Bos or Bison sp.: A bovid Ovis cf. antiqua: Sheep

With the exception of Dicerorhinus kirchbergensis, widely regarded as an interglacial browser<sup>24</sup>, these animals could be grouped into a fairly unremarkable cold climate assemblage, although most of the larger species tolerate a wide range of thermal environments. Nothing in this collection indicates a date more precise than the later part of the Pleistocene. Sutcliffe and Kowalski<sup>25</sup> have suggested that Microtus gregalis is confined to the Devensian Stage (Last Glaciation) in Britain, even though it is recorded from earlier deposits in adjacent parts of continental Europe. This proposal would seem unlikely. The characteristic rodent assemblage of the colder regions of the northern continents was well established in the early Pleistocene<sup>26</sup>, and small mammal faunas closely parallel to that of Pontnewydd still exist over wide areas of northern Eurasia, Alaska and Arctic Canada. Successive cold stages during the Pleistocene could have led to the spread of rather similar faunas into Britain, particularly as low sea levels would allow free migration from the continental landmass. One would not expect any one form to be specifically excluded from the British region under these circumstances and the occurrence of Microtus gregalis from a pre-Devensian context is not surprising. Note here the first record of Ovis cf. antiqua in Britain.

The fragmented and abraded nature of the animal remains, together with the occurrence of robust limb bones that have been shattered and bent into bizarre shapes, support the suggestion that the Breccias have been sludged into their present position. Any original stratigraphy seems to have been completely destroyed and the fauna almost certainly has been mixed by this sludging process, but the abundance of carnivore remains, particularly those of adult and juvenile bears, implies that a genuine cave assemblage is present.

We make no comment about the occurrence of animals, noted by Boyd Dawkins<sup>2</sup> and McKenny-Hughes<sup>3</sup>, that would now be assigned to the Ipswichian s.s. ('Last Interglacial'). These include *Hippopotamus amphibius*, *Palaeoloxodon antiquus*, *Dicerorhinus hemitoechus* and *Crocuta crocuta*. None of these records have been substantiated by recent excavation. The evidence of stable isotope analysis that the cave may have been closed during the Ipswichian leaves open the possibility that the animals may have come from a localized entrance deposit, since destroyed.

#### Archaeological material

The new archaeological finds (Fig. 5) comprise some 300 artefacts. Stratified examples were located, along with the fauna, within the breccia units and in the Intermediate Complex. No in situ settlement survives and all of the artefacts have been transported into the cave by mass movement. We cannot demonstrate that the finds represent a single industry but the location of the site far outside the known distribution of British Acheulian sites would render multiple occupation less likely. It is uncertain as to what part of the fauna may constitute the food bones of the Palaeolithic hunter-gatherer community (or communities).

Combination of the TL and uranium dates and faunal evidence suggests that the occupation(s) took place within the time range of Oxygen Isotope Stage 7/earlier Stage 6. This dating makes sense in climatic terms in so far as the occupation seems to have preceded the onset of glaciation later in Stage 6 when deep-sea core data<sup>27</sup> indicate an increase in ice-volume, and stable isotope studies of northern England speleothems<sup>28</sup> suggest glaciation from 170 to 140 kyr. Radiometric dating of the Barbados coral terraces<sup>29</sup> suggests a major eustatic lowering of sea level, bracketed by the Kendal Hill and Rendezvous Hill terraces between 180 and 125 kyr.

The archaeological material has been considered elsewhere<sup>30</sup>. The principal artefactual components are handaxes of Acheulian types, other implements (principally scrapers) and Levallois débitage (including cores) (Fig. 6). The nature of the artefacts and small size of the potential living-area in the cave entrance suggest that the cave was probably used as a temporary butchering site. The industry finds little close comparison with other sites either in Britain or in adjacent continental areas.

Of the 300 artefacts recovered about 40 are of flint or chert and most of the remainder are of siliceous igneous, pyroclastic and volcaniclastic rocks. These specimens, so far only examined macroscopically, show evidence of having suffered a low-grade of metamorphic recrystallization, whilst in addition a cleavage is variably developed within the rocks, being most pronounced in the fine-grained specimens.

The variety of rock types, the low grade metamorphic crystal-lization and the poorly developed cleavage, suggest a source either in North Wales or the English Lake District. Their presence on the site, whether as artefacts in the Breccias or as unmodified pebbles in both the Breccias and Basal Sands and Gravels, suggests glacial transport to the Elwy Valley before oxygen isotope Stage 6. Whatever the origins of the other rocks, the flint (which has been recognized so far only from the Breccias) must have come as a component of the Irish Sea drift<sup>31</sup>. This drift may be compared with the "Main Irish Sea Glaciation", of Embleton<sup>32</sup> whose hypothesis of the cutting of the lower Elwy Valley as a result of local glacial diversion of the river by inland penetration of Irish Sea Ice would then presuppose another such event earlier in the glacial Pleistocene, unrecognized as yet in the local terrestrial till sequences.

The Pontnewydd excavations will continue for several more seasons to increase the statistical validity of the artefactual and other samples; to improve the dating and comprehension of the stratigraphy; to establish the relationship of the site to the local Quaternary geology and geomorphology; and, if possible, to recover more hominid remains.

We thank D. Q. Bowen, Derek Roe, George Boon and Roger Jacobi for reading this paper. We acknowledge financial assistance from the Board of Celtic Studies, the Cambrian Archaeological Association, the Society of Antiquaries of London, the British Academy, the L. S. B. Leakey Foundation and the Social Sciences and Humanities Research Council (Canada). The illustrations are the work of Theya Molleson, Paul Hughes, Margaret Ehrenberg, BM(NH) Photographic Studio and Eric Broadbent. We thank Ken Planter and Colin

Williams for photographic reduction and mounting of the figures and Monica Cox for typing the manuscript. The site being a scheduled ancient monument, the work proceeded with the sanction of the Ancient Monuments Branch of the Welsh Office,

# Intragenic amplification and divergence in the mouse $\alpha$ -fetoprotein gene

# Fern Alexander Eiferman, Peter R. Young, Richard W. Scott & Shirley M. Tilghman

Institute for Cancer Research, Fox Chase Cancer Center, Philadelphia, Pennsylvania 19111, USA

The DNA sequences of the 14 exon junctions in the murine  $\alpha$ -fetoprotein gene were determined using cloned genomic DNA. When these exons were examined with respect to the polypeptide segments they encoded, a direct correspondence between a threefold repeat of four exons and three protein domains was observed. Nucleotide sequence comparisons among the four exons of each domain were used to deduce the likely structure of the primordial domain, and the order and mechanism of its triplication to form the tripartite ancestral gene from which both \alpha-fetoprotein and serum albumin arose. Sequence homologies among the four exons that constitute a single domain also suggest that they were derived, at least in part, from a common sequence which underwent successive amplification and divergence.

MAMMALIAN α-fetoprotein (AFP) and serum albumin are useful models for elucidating early events in the evolution of a multi-gene family. Their genes arose through duplication of an ancestral gene 300-500 Myr ago<sup>1-6</sup>. They have remained linked on chromosome 5 in the mouse, with the albumin gene 14 kilobases (kb) of DNA upstream from the AFP gene

Brown<sup>9,10</sup> first suggested that the ancestral gene itself had been formed by amplification and divergence of a simpler sequence when he recognized a thrice-repeated pattern of cysteine-cysteine disulphide bridges in the amino acid sequences of human and bovine albumins. He concluded that the albumin gene must have arisen from the triplication of a primordial domain, consisting of ~190 amino acids. The amino acid sequence of murine AFP also shows this threefold repeat pattern1,6

We have inquired into the genetic basis for the tripartite structure of the AFP/albumin ancestor. An examination of the structures of their genes in the mouse<sup>2</sup> revealed that both are comprised of 15 coding blocks or exons, which are interrupted by 14 intervening sequences. The sizes of the 15 corresponding exons in each gene were estimated by electron microscopy of R-loops, and shown to be very similar. Of particular interest was the observation that the 12 internal exons of either gene, numbers 3-14, seemed to be composed of three similar sets of four exons, based on their sizes. We therefore proposed that the three protein domains had been generated by the triplication of a primordial gene consisting of four exons<sup>2</sup>. To test this, the borders of the 15 exons of the AFP gene were located by DNA sequencing using cloned genomic DNA.

#### Nucleotide sequences of the splicing iunctions of the AFP gene

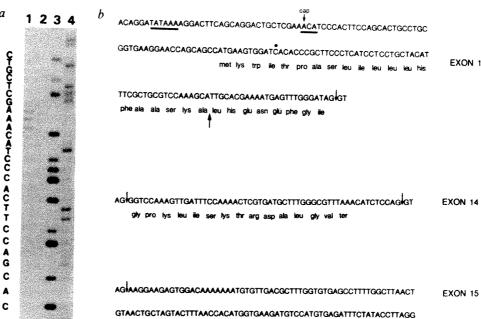

The borders of the exons in the mouse AFP gene (see Fig. 1) were determined by the procedure of Maxam and Gilbert 17. In some instances where the determination of a splicing site was unequivocal from sequences of one side of the intron, the sequence at the other side was not determined. The intron junction sequences closely resemble the consensus sequence suggested by Lerner et al. 12, and no exceptions to the GT-AG rule proposed by Breathnach et al. were seen 13. Indeed, because of the presence of sequence redundancy at 12 of 14 borders, the exact locations of the splice sites can only be assigned on the basis of these four invariant nucleotides.

The location of the mRNA cap site was determined by an S<sub>1</sub> nuclease protection experiment<sup>14</sup> shown in Fig. 2a. A 100nucleotide DNA fragment, labelled on the anticoding strand at a Sau3A site in exon 1, was hybridized to AFP mRNA. The S1 nuclease-resistant fragments (lane 1) were sized on an acrylamide gel by comparison with chemical degradation products of the same DNA fragment (lanes 3, 4). Three prominent bands, 42-44 nucleotides upstream from the AUG initiation codon, were observed. From a comparison of the nucleotide sequence at the putative cap site with previously reported cap site sequences in other genes<sup>15,16</sup>, we have tentatively identified the first adenine residue of the underlined ACA triplet in Fig. 2b as the cap site. The other bands presumably reflect imprecise cutting by S<sub>1</sub> nuclease as they did not decrease with increasing S<sub>2</sub> nuclease concentration (lane 2). A 'TATAA' sequence, or

Fig. 1 The sequences at the splice junctions in the AFP gene. The partial DNA sequences spanning the 14 splice junctions of the murine AFP gene were determined using cloned genomic fragments<sup>2</sup> and the procedures of Maxam and Gilbert<sup>11</sup>. The tentative locations of the 15 exons were originally determined by R-loop techniques and a direct comparison of a detailed endonuclease restriction map of the cloned genomic fragments with the restriction map of its cDNA <sup>1,2,46</sup>. The positions of the junctions, indicated by the vertical lines and the sizes of the 15 exons, shown in the first column, were deduced by comparing the genomic and cDNA sequences <sup>1</sup> and by the presence of the invariant GT and AG dinucleotides (underlined) at the 5'- and 3'-intervening sequence borders, respectively. The sequences of the last two or three complete in-frame exon triplet codons at the 3' junction are followed in each instance by the first seven nucleotides of the adjacent intervening sequence. The last seven nucleotides of that intervening sequence and the first two or three complete triplet codons of the next exon follow the dotted line which represents those remaining intervening sequences. The in-frame triplet codons are designated by the spacing of the exon sequences. The consensus sequence of Lerner et al.<sup>12</sup> for the splice junctions is shown at the bottom. The designations used in the text for domains (I, II and III) and subdomains (A-D) in the gene, are shown on the

Fig. 2 The sequence at the 5' and 3' termini of the AFP gene. a, The approximate location of the first nucleotide of AFP mRNA was determined by an S<sub>1</sub> protection experiment<sup>14</sup>. One microgramme of fetal yolk sac poly(A)\* mRNA, which is 10-20% AFP mRNA, was hybridized to a denatured 100-bp Sau3A-HincII fragment derived from pAFP14Z (ref. 2), which was end-labelled at the Sau3A site within exon 1 on the anticoding strand (asterisk in b, excn 1). The hybridization and S, nuclease digestion were performed according to the procedures of Favaloro et al. 47. The pro-tected DNA fragment was electrophoresed in a 10% urea acrylamide gel. Lanes 1, 2: S<sub>1</sub> nuclease (Miles) used at 200 and 500 U ml<sup>-1</sup>, respectively. Lanes 3, 4: To size the S<sub>1</sub> digest gel migration, the same Sau3A-HincII fragment was subjected to chemical degradation<sup>11</sup> for the G reaction (lane 3) and A reaction (lane 4). The complement of the determined sequence is shown on the left, so as to correspond to the coding strand. The sizes of the S<sub>1</sub>-protected fragments were determined by comparison with the nucleotide sequence, taking into account the fact that the chemically degraded fragments lack the modified base. b. The nucleotide and amino acid sequences of the first and last two exons. In exon 1, the

<u>AATAAA</u>AACTTTTCAACTATTTCTCTTCTCCTAGTCTGCTTTTTTTAT

underlined ACA trinucleotide identifies the likely position of the cap sequence, as determined in a. The underlined TATAA sequence 30 bp upstream from the cap site is the Hogness box. The 3'-splice junction is shown by a downward arrow and the junction between the 20-amino acid signal peptide and the mature protein is designated by the upward arrow. The Sau3A site labelled in a is shown by the asterisk. In exon 14, the splice junctions are designated by the downward arrows and the terminator codon TAA is shown as 'ter'. In exon 15, the 5'-splice junction is shown by the downward arrow. The signal for poly(A) addition, AATAAA, is underlined and the upward arrow designates the poly(A) addition site<sup>6</sup>.

Hogness box, thought to be required for precise initiation by RNA polymerase II, is found 30 base pairs (bp) upstream from the cap site (Fig. 2b).

The termination codon for AFP synthesis, TAA, occurs in exon 14, as shown in Fig. 2b. The 3'-untranslated sequence in this exon differs at three positions from our previous report¹. Although we cannot eliminate sequencing errors as an explanation, it is likely that these result from the fact that the cDNA and genomic clones were constructed from different inbred strains. The sequence in Fig. 2 agrees with that of Law and Dugaiczyk⁶. Exon 15, the last exon of the AFP gene, contains only 3'-untranslated sequence. The poly(A) addition signal, AATAAA¹7.18, is 120 bp from the start of this exon (Fig. 2b) and the poly(A) addition site is an additional 15 bp downstream⁶.

# Coincidence of genetic and functional domains

An examination of the sizes of the internal 12 exons in the AFP gene (Fig. 1) strengthens the original premise of a thrice-repeated pattern. The gene can be readily divided into three sets of four exons designated subdomains A-D based on their sizes; this excludes the first two and the last exons. Subdomains vary in size within families by multiples of 3 bp, and thus any insertions or deletions within subdomains do not change the reading frame of downstream exons. There is also conservation of the location within a triplet codon of the 5' and 3' borders of each family (Fig. 1).

Figure 3 shows the pattern that emerges when the borders delineating the exons are superimposed on the protein. It is immediately apparent that all the exons of any one family encode segments of the protein that are identical with respect to the location of the disulphide bridges. For example, each subdomain C (closed circles, Fig. 3) encodes an equivalent double loop region or subdomain in each of the three domains.

Are the three genetic domains defined by the four-exon repeat coincident with functional domains in either AFP or albumin? One can consider the first and last exons, which lie outside the domains, as functionally distinct in that the first exon encodes the signal peptide and the last exon encodes the

3'-untranslated sequence and poly(A) addition signal. In many but not all secreted proteins, the signal peptide exon is physically separated from the rest of the gene.

The active binding sites in mammalian AFPs are poorly characterized. In the case of albumin, experiments on the intact protein and on isolated fragments corresponding to domains have localized binding sites to specific domains. The high-affinity long-chain fatty acid binding site is in domain III, the bilirubin binding site in domain II and the indole binding sites in domain I Domains I and II exhibit weaker fatty acid binding sites, suggesting that these are remnants of the high-affinity site in domain III, the putative primordial domain (see below). Interestingly, copper(II) or nickel(II) binding is performed by the first three amino acids of the mature protein, which is separately encoded by exon 1<sup>19</sup>. These studies are consistent with the notion that the protein domains are functionally distinct and that the selective pressure to maintain amplified domains lay in the generation of functional diversity within the protein.

The relationship between genetic and functional domains has been clearly demonstrated only in instances where there has been intragenic amplification and divergence, as has occurred in the AFP/albumin ancestral gene. The other compelling example occurs in the immunoglobulin heavy-chain constant region genes, where each of the four constant region gene domains has been correlated with structural or functional protein domains<sup>20-25</sup>. Stein et al.<sup>26</sup> have reported a triplication of two internal exons in the chicken ovomucoid gene which possibly correspond to the three binding sites for protease inhibitor in the protein.

Amplification of genetic domains is facilitated by the presence of pre-existing intervening sequences; thus, as suggested by Gilbert<sup>27</sup> and Darnell<sup>28</sup>, intervening sequences serve to increase the probability of useful recombination during unequal crossing-over. Following amplification, the presence of intervening sequences then decreases the likelihood of genetic recombination and subsequent deletion of DNA, because the intervening sequences themselves rapidly diverge<sup>29</sup>. In the case of the albumin and AFP genes in the mouse, which are located<sup>8</sup>

a, Nucleotide homologies of pairwise comparisons within subdomain families for the alignments illustrated in Fig. 4a are shown. In each case, the upper value represents the per cent homology, codon gaps not being taken into consideration. The bottom value is the probability (P) of finding this homology or more by chance, taking the length of the sequences being compared into account. It is based on the normal approximation to the binomial distribution, using the formula

$$p = 1 - \Phi\left(\frac{H - np}{\sqrt{npq}}\right)$$

where n is the standard length of the sequence, H is the number of homologous bases, p is the probability of finding a match at any position (in this case p = 0.25), and q = 1 - p. (NS = not significant.) b, Nucleotide homologies of pairwise comparisons between subdomains A and C are shown, using the alignments illustrated in Fig. 4a.

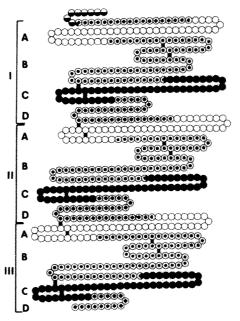

Fig. 3 The coincidence of genetic and protein domains. The 585 circles in the diagram represent the amino acids of mature AFP, drawn to connect adjacent cysteine-cysteine disulphide bridges, shown by the connecting bars<sup>1,10</sup>. The amino acids encoded by exon 1 ⊕, the three A subdomains ⊙, the three B subdomains ⊙, the three C subdomains ⊕ and the three D subdomains and exon 2 ♠, are drawn, and designated on the left of the diagram according to usage in Fig. 1 and the text. In cases where a splice junction interrupts an in-frame triplet codon, the amino acid is drawn with two symbols.

13.5 kb apart on chromosome 5, this has probably contributed to the maintenance of the two genes in tandem.

When one examines genes such as insulin<sup>30,31</sup>, lysozyme<sup>32</sup> and alcohol dehydrogenase<sup>33</sup>, in which there is no apparent intragenic amplification, the coincidence of genetic and functional domains is far less evident. Gilbert<sup>27</sup> has proposed that the selective advantage of intervening sequences lay in the ability of a cell to recruit by translocation and recombination discrete genetic domains for the assembly of new genes, thereby markedly increasing the rate of evolution. One test of such a model would be the demonstration that genes are composed of genetic elements or exons encoding specific functions of the protein. Structural data, and the observation that the haem binding site of  $\alpha$  or  $\beta$  globin is encoded by the middle exon of the three-exon gene, have been cited by several groups as support for this model  $^{31,32,34-36}$ . Particularly intriguing is the finding that this exon is in fact split in leghaemoglobin of soybean  $^{37}$ , as was predicted by  $^{36}$  on the basis of structural arguments alone.

#### Mechanisms of divergence between domains

A comparison of related subdomains provides an opportunity for identifying evolutionary mechanisms that have generated domain diversity. To facilitate such a comparison, each subdomain family was aligned using the optimal nucleotide sequence homologies found by the computer programs of Staden<sup>38</sup> and an adaptation of the Queen and Korn<sup>39</sup> program. The minimum number of in-frame gaps have been introduced to maintain lengths of uninterrupted homology.

Figure 4a shows the alignments for each subdomain family, and Table 1 enumerates the nucleotide homologies within and between subdomain families, together with the probabilities that the number of matches could have arisen by chance. The three C subdomains are identical in size, and appear to have incurred no insertions or deletions. They have been aligned in Fig. 4a with a two-codon gap to facilitate their comparison with the A family, discussed below. They are also the most closely homologous family, with a 47% nucleotide homology between IC and IIC, a 44% match between IC and IIIC and a 36% match

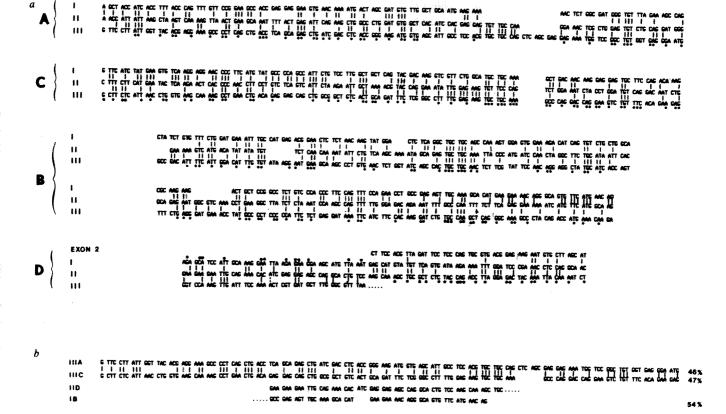

Fig. 4 The alignment of sequence homologies within subdomain families. a, The nucleotide sequences of each of the 13 internal exons are aligned in their corresponding subdomain families. Their alignments were determined by optimizing nucleotide sequence homologies in pairwise sequence comparisons within families. Within each family, homologies between domains I and II and domains II and III are indicated by the vertical lines, and the homologies between domains I and III are shown as asterisks below domain III. The sequences are displayed with spaces between in-frame codons, so that codon gaps in subdomains are evident. The two-codon gap in the C family alignment facilitates the comparison of the A and C families. b, The bottom alignment shows a comparison between representatives of each subdomain family, IIIA, IIIC, IID and IB. The entirety of IIIA and IIIC are aligned, and the vertical lines between them identify homologous nucleotides. The first 57 bp of IID are compared with internal regions of IIIA, IIIC and the last 50 bp of IB. The homologies between IID and each of these are shown on the right. The probabilities that these could have arisen by chance, using the formula in Table 1, are  $1.64 \times 10^{-4}$  (IID vs IIIA),  $5 \times 10^{-5}$  (IID vs IIIC) and  $1.3 \times 10^{-6}$  (IID vs III).

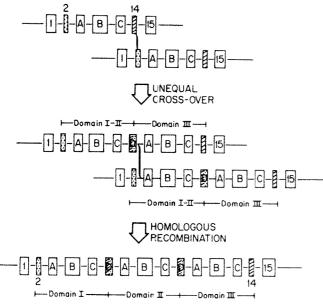

Fig. 5 A model to explain the triplication of the primordial domain. A model for the generation of the three domains in the ancestral AFP/albumin gene is illustrated. The seven exons comprising the entire primordial gene consisted of the present exon 1 containing the signal sequence, exon 2, subdomains A, B and C, exon 14 containing the termination codon, and exon 15. An unequal cross-over event between exons 2 and 14 resulted in the formation of a D exon. This created a two-domain gene, equivalent to domains I-II and III. A subsequent homologous recombination event then gave rise to domains I and II, as the result of a duplication of domain I-II. This model takes into account the sequence relatedness of the three domains in Table 1, as well as the chimaeric nature of the D subfamily.

between IIC and IIIC. The A subdomains each differ in size, and their homologies range from 35 to 42%, the longest, IIIA, being 139 bp long, 9 bp longer than IIA. A single gap in IIA, 30 bp from the 3' border, represents the most likely position of either a deletion in IIA or an insertion in IIIA. Subdomain IA contains an additional gap of three codons, which has been positioned to the 5' side of the gap in IIA. In this case, however, there are several other possible locations, and the alignment of the four codons to the right of the gap is tentative.

By comparing the A subdomains with their counterparts in the rat albumin gene, whose sequences were determined by Sargent et al. 40.41, it is possible to date approximately when these gaps occurred. Although subdomains IIA and IIIA are identical in size in both genes, albumin IA is four amino acids longer than AFP IA. Therefore, one would infer that the size difference between IIA and IIIA existed before the AFP/albumin gene duplication, tentatively placed at 300-500 Myr ago<sup>2</sup>, whereas the alteration in IA occurred after it.

Alignment of the B subdomain family requires that two members contain deletions, at different places in the sequence. As illustrated in Fig. 4, IB (212 nucleotides) contains two gaps, one of 9 bp and one of 3 bp. IIB (215 bp) contains a gap of one codon at its 5' border, which is the only possible example of a mutation at a splice junction, and a second codon gap elsewhere. The alterations in the B subdomains are apparently unrelated, and probably arose independently after the domain triplication by deletions, for otherwise one must postulate two insertions at each of the gaps. This is in keeping with the finding by de Jong and Ryden<sup>42</sup> that deletions are far more common than insertions as evolutionary mechanisms of divergence. The members of the B family are less homologous to one another than are those of the A or C families, with pairwise homologies of 32–39%.

The D family of subdomains consists of four exons, exons 6 (ID), 10 (IID), 14 (IIID) and 2. This classification is based on several different lines of argument, as the total percentage homology between members of this family is less than in any of the other families (see Table 1). Exons ID and IID are identical in size, with the corresponding cysteine residue occurring at the same position, but only share marginal nucleotide homology. This is not surprising, given that of all the exons in the AFP gene, that encoding ID is the least homologous to the corresponding exon in the rat albumin gene<sup>41</sup>. Thus, we consider that there is little selective pressure to retain the constancy of the nucleotide sequence of ID, although there is obviously considerable pressure to maintain the size of this subdomain at 98 bp. The relationship between IID and IIID is most evident when each is compared with an internal region of either IIIA or IIIC. As shown for IID in Fig. 4b, its first 57 bp are 46 and 47% homologous to a 57-bp internal segment of IIIA and IIIC, respectively. Similarly, IIID is 45% homologous to the same region in either IIIA or IIIC (data not shown). Finally, the inclusion of the second exon in this family, which had previously been considered outside the domain repeats, is based on a 40% homology between it and the final 52 bp of IID, as shown by the asterisks below IID in Fig. 4a.

# Internal homologies shared among subdomain families

An examination of the evolution of the primordial domain itself was initiated when marked similarities between the A and C subdomain families became apparent. They are very similar in size and in the pattern by which the exon junctions occur in the reading frame. In fact, it is possible to align them as a sixmember family (see Fig. 4a), based on significant nucleotide homologies which they share (Table 1). As shown in Fig. 4b and Table 1, subdomains IIIA and IIIC are as homologous to each other, 47%, as the most homologous pair within either family, IC and IIC. Thus, subdomains A and C must have arisen from a duplication which preceded the formation of the primordial domain.

Several conclusions about the history of the A/C family can be drawn by comparing the six related subdomains. It is likely that the original A/C exon was 133 bp long, and that the additional 6 bp in IIIA resulted from an insertion (Fig. 4b). Otherwise at least two exons would have had to undergo independent but identically positioned deletions before their further amplification. For the same reason, the gaps present in IA and IIA are the likely consequence of deletions. It has been proposed, based on sequence analysis of globin genes in mammals, that deletions and insertions occur preferentially in regions composed of short direct repeats<sup>15</sup>. Evidence of such an event is seen when the 3'-untranslated sequence of the mouse albumin gene is compared with that of the rat<sup>8</sup>. If such a sequence was present in the primordial A/C subdomain, this could have allowed independent deletions at the same location. However, no such repeated sequence in IIIA is apparent today.

We next investigated whether sequences existed in the other two subdomain families, B and D, which would suggest a common ancestry with A and C. The results indicate that all four subdomain families exhibit regions of homology with one another. In particular, as aligned in Fig. 4b, the first 57 bp of subdomain IID are 54% homologous with the last 50 bp of IB. This same region of IID is homologous with the middle of IIIA and IIIC. A more detailed analysis of these inter-subdomain relationships is now under way, but it is already evident that all four exons that constitute a domain are related, and were probably initially derived, at least in part, from one exon.

The sequence of events leading from a single exon to the primordial domain, composed of exons of quite different sizes, must have included amplification of that exon (of as yet undetermined length) creating multiple adjacent copies separated by intervening sequences. Following their divergence, separate exons could have been consolidated by unequal cross-

overs during recombination or by removal of intervening sequences, similar to that which has occurred in a rat insuling gene  $^{30}$  and in a pseudo  $\alpha$ -globin gene in the mouse  $^{43}$ . Such a sequence of events has been postulated for the type  $1\alpha 2$  collagen gene of the chick, which contains multiple homologous 54-bp exons  $^{44}$ . Mutations within junction sequences could also result in exon border changes, altering the size of individual exons and adding segments unrelated in sequence to the initial exon. Such processes would eventually have led to the establishment of a primordial gene, the exons of which varied in size, but which were at least partially related in sequence. Brown  $^{9.10}$  and McLachlan and Walker  $^{45}$  have presented a

model to explain the generation of the primordial domain, based on the positions of the cysteine-cysteine bridges within a domain. Their model proposed that a 73-amino acid segment triplicated, and then a middle segment was consolidated by deletion. In genetic terms, their 73-amino acid segment would have been encoded by exons 2, A and 14, and the triplication would have generated a gene composed of 9 exons flanked by exons 1 and 15. The subsequent generation of exon B from the internal exons 14, 2, A, 14 and 2 must have involved deletions of both coding sequence and intervening sequences, leaving a primordial domain composed of exons 2, A, B, A (C) and 14. The homologies we observe between exon families certainly support a mechanism of this kind although the precise details of the deletions have not been elucidated. Note that the homologies between exons A and 14 also argue that intragenic amplification must have occurred before the establishment of the 73-amino acid segment.

#### Order of domain triplication

Pairwise comparisons between the nucleotide sequences of the three domains can potentially be used to trace the order of the two successive duplications of the primordial domain. The sequence homologies between domains reflect, in part, the evolutionary time between successive domain duplications, the most homologous corresponding to the most recent duplication. However, it should be emphasized that other evolutionary pressures exerted at both the nucleotide and amino acid levels have contributed to the rate of divergence of the three domains, and may serve to obscure the divergence based on time.

Although comparison of the homologies between entire domains (Table 1) shows domains I and II (39%) to be more closely related than domains I and III (35%), this difference is not statistically significant by a  $\chi^2$  test. Using this test, the only significant difference between the homologies within any subdomain family occurs in the C family, where the relatedness of domains I and II is significantly greater than that of II and III. Nevertheless, it is also evident that in three of the four families (B, C and D), domains I and II are the most homologous, and in subdomains A, B and D domains I and III are most distantly related. It seems likely, therefore, that domain II is the evolutionary link between domains I and III, and the order of triplication was domain III giving rise to a domain which subsequently duplicated to form domains I and II. A brief examination of rat albumin sequence40 reveals that the overall order of relatedness between domains is the same as that in AFP.

This order, which was originally predicted by Brown<sup>10</sup> based solely on amino acid homologies in bovine and human albumins, is supported by a model to explain the generation of the D subfamily. As discussed earlier, and represented in Fig. 4, this family is composed of two 98-bp exons, ID and IID, which are homologous at their 5' termini to exon 14 (IIID), and at their 3' termini to exon 2. Possibly, at one time exons 2 and 14 were each entire subdomain Ds, and in two independent events the beginning of exon 2 and the end of exon 14 were deleted. Alternatively, one could postulate a copy of D split, creating two separate exons. If an exon division did occur, it is difficult to envision how exons 2 and 14 came to lie on opposite ends of the gene.

We favour a model in which exons 2 and 14 flanked the primordial domain, corresponding to the A, B and C subdomains of domain III (Fig. 5). During the first unequal crossover in the triplication, these flanking exons fused to form subdomain D. This could occur in one step, with the cross-over occurring within the two exons, eliminating the termination codon and generating a two-domain protein. Alternatively, it could occur in two steps, the first step being a cross-over in the intervening sequences, followed by a fusion of exons 14 and 2. In the latter case, however, the resulting protein would still only comprise a single domain, until subsequent events removed the termination codon in the fused subdomain. This second alternative seems unlikely, as it would place the downstream domain under no selective pressure. In either case, the one strong constraint placed on the fusion would be that the reading frame of the downstream exons be preserved. The subsequent duplication of the left domain, by homologous unequal crossing-over, would generate domains I and II, in agreement with the overall relatedness of domains I and II over domain III.

The model in Fig. 5 differs slightly from our original proposal<sup>2</sup>

in that the primordial genetic domain is composed of five rather than four exons, and exon D is only generated by the fusion of two of these during or after the first duplication. Thus, one could define a domain as consisting of the equivalents of exons 2, A, B, C and the first half of exon D. This is precisely the way in which the three protein domains in albumin were originally delineated 10.45. The second duplication of exons I-IIA, B, C and D is in keeping with our original model.

# Membrane asymmetry in epithelia: is the tight junction a barrier to diffusion in the plasma membrane?

# Paul R. Dragsten\*, Robert Blumenthal\* & Joseph S. Handler\*

\* Section on Membrane Structure and Function, LTB, DCBD, National Cancer Institute and ‡ Laboratory of Kidney and Electrolyte Metabolism, National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

Membrane-bound lectins and some lipid probes are incapable of passing through the tight junction region of epithelial cell membranes. The lectins are immobile on the cell surface, but lipid probes diffuse freely in the membrane. The ability of a lipid probe to pass the tight junction is correlated with its ability to 'flip-flop' to the inner monolayer of the cell membrane bilayer.

EPITHELIA form tight monolayers of cells in many organs and control the passage of solutes across the monolayer. Individual cells are asymmetric, with the apical (mucosal) and basolateral (serosal) surfaces exhibiting different membrane morphology, ionic permeabilities, distribution of enzymes and sensitivity to hormones and drugs<sup>1-4</sup>. This asymmetry is correlated with the

presence of an intact tight junction which encircles the cell at the boundary separating the apical and basolateral surfaces<sup>4-11</sup>. The tight junction seems to form a barrier to extracellular penetration of solute and water across the monolayer<sup>4</sup>.

The mechanisms of development and maintenance of cell asymmetry are unknown. It has been suggested that the tight junction may act as a barrier to lateral diffusion of membrane constituents between apical and basolateral surfaces<sup>4,6,8,9,11</sup>. We report here the results of experiments designed to test that

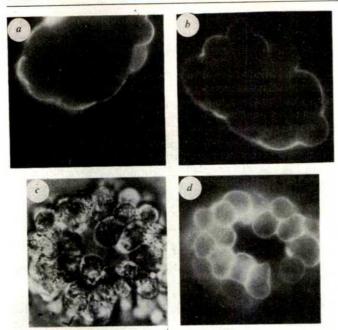

Fig. 1 Fluorescence micrographs of domes of A6 cell monolayers labelled with tetramethyl rhodamine-conjugated wheat-germ agglutinin (a),  $AFC_{16}(b)$  and  $dilC_{16}(d)$ . c, Brightfield photograph of the dome in d. In all cases, the cells were labelled by adding the fluorescent probe to the medium bathing the apical surface of the cell monolayer. In this way, only apical membranes were labelled initially. The plane of focus is part way up a dome of cells. In this geometry, labelling of the apical surface alone appears as a series of arcs, as in a and b, and labelling of the entire plasma membrane appears as complete rings, as in d. The apparent gap in the ring of fluorescent cells in d is due to a cell which was weakly labelled with dilC<sub>16</sub>, as occasionally happens with this probe. Labelling conditions were:  $25 \,\mu \mathrm{g} \,\mathrm{ml}^{-1}$  wheat-germ agglutinin for 20 min;  $10 \,\mu \mathrm{g} \,\mathrm{ml}^{-1}$  AFC<sub>16</sub> for  $10 \,\mathrm{min}$ ;  $5 \,\mu \mathrm{g} \,\mathrm{ml}^{-1}$  dilC<sub>16</sub> for  $5 \,\mathrm{min}$ . × 600.

suggestion. We selectively labelled with a fluorescent probe one surface of a confluent monolayer of epithelial cells grown in culture, and then determined the rate at which the probe diffused laterally in the membrane and whether it could move through the region of the tight junction to the side of the cell not labelled initially (for example, from the apical to basolateral surface). We first measured lateral diffusion coefficients using the technique of fluorescence photobleaching recovery (FPR)<sup>12</sup>, and then monitored the amount of fluorescence on the apical and basolateral surfaces to determine any movement through the tight junction. We found that cell-surface sites labelled with fluorescently conjugated lectins were unable to move through the region of the tight junction and, in fact, were completely

Fig. 2 Molecular structure of the fluorescent lipid probes. AFC<sub>16</sub>, 5-(N-hexadecanoyl)aminofluorescein; AFC<sub>12</sub>, 5-(N-dodecanoyl)aminofluorescein (Molecular Probes); diIC<sub>16</sub>, 3,3'-dihexadecylindocarbocyanine iodide (given by Dr A. Waggoner); NBD-PC, 1-acyl-2-(N-4-nitrobenz-2-oxa-1, 3-diazole)-aminocaproyl phosphatidylcholine (Avanti). AFC<sub>12</sub>, AFC<sub>16</sub> and diIC<sub>16</sub> did not affect transepithelial resistance when added to the apical solution of A6 epithelia grown on a porous support (Millipore filter).

immobile with respect to lateral diffusion. On the other hand, fluorescent lipophilic probes diffused freely, and fell into two categories: those capable of passing the region of the tight junction by lateral diffusion in the membrane, and those incapable of penetrating the tight junction. These results show that epithelial cells are capable of segregating membrane constituents as small as lipids on one side of the tight junction, thus suggesting a mechanism whereby epithelia may maintain different lipid compositions on the apical as opposed to the basolateral membranes<sup>3,13</sup>. As the ability of a lipid probe to pass through the tight junction is also correlated with its access to the inner monolayer of the cell membrane bilayer, we suggest that the tight junction presents an impassable barrier to lipid components only in the outer leaflet of the membrane.

#### Lectin probes

Continuous epithelial cell lines were grown to confluency in culture according to methods published elsewhere 4.14.15. Cell lines used were A6 (derived from toad kidney), LLC-PK<sub>1</sub> (from pig kidney) and MDCK (from dog kidney). These cultures grow with their apical surface uppermost, allowing easy labelling of the apical membrane with fluorescently conjugated lectins. Preparations with exposed basolateral surfaces were obtained by gently detaching part of an intact sheet of cells with a stream of medium from a syringe and folding the flap of cells thus produced back over a glass disk (5 mm diameter, 1 mm high) with the basolateral surface uppermost. This inverted sheet of cells was held in place by a ring clamped around the disk.

Wheat-germ agglutinin and peanut agglutinin lectins were used to label directly both basal and apical surfaces. However, if one surface was labelled, the probe did not redistribute to the other side of the cell, as determined by direct observation with high resolution fluorescence microscopy. It was found that the most convenient geometry for viewing the sidedness of the label was to focus the microscope part way up a dome of cells. Domes are regions of the monolayer which have detached from the dish and bulged upwards due to epithelial transport of solution across the monolayer from apical to basal surface, where it becomes sequestered inside the dome of cells thus produced16. By focusing part way up the dome, apical and basolateral surfaces on individual cells are in focus simultaneously. Thus, if the entire plasma membrane is labelled, each cell in the cross-section of the dome defined by the plane of focus of the microscope will appear as a complete ring of fluorescence. If only one membrane is labelled, incomplete fluorescent rings, or arcs, will be seen. Figure 1a shows such arcs on a dome of A6 cells having apical membranes stained with rhodamine-conjugated wheat-germ agglutinin.

As the lectin-labelled membrane components were unable to penetrate the tight junction, we next determined whether the

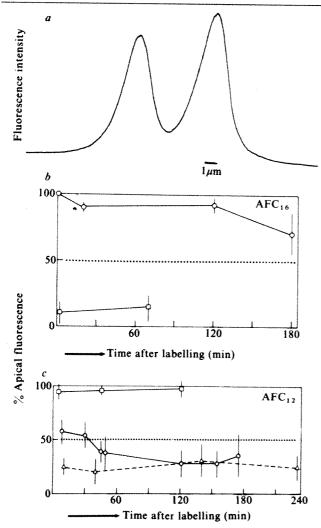

Fig. 3 a, Fluorescence intensity tin arbitrary units) excited by focused krypton ion laser beam (at 531 nm) as the microscope focus was scanned through an A6 cell labelled with diIC<sub>14</sub>. The peak on the left is due to basal membrane fluorescence, and that on the right due to apical fluorescence. b, Mean ( $\pm$ s.d.) per cent fluorescence excited from apical membrane as a function of time after labelling cells with AFC<sub>16</sub>.  $\bigcirc$ , Apical membrane initially labelled;  $\square$ , basolateral membrane initially labelled. The 476 krypton laser line was used to excite fluorescence. c, Mean ( $\pm$ s.d.) per cent fluorescence excited from apical membrane as a function of time after labelling cells with AFC<sub>12</sub>.  $\bigcirc$ , Apical membrane initially labelled;  $\square$ , temperature reduced to 10 °C and apical membrane labelled.

tight junction formed a barrier to lateral diffusion of the label in the membrane. Previous measurements of lateral diffusion of wheat-germ agglutinin binding sites on fibroblasts have yielded diffusion coefficients of  $\sim\!\!2\times10^{-11}$  to  $2\times10^{-10}\,\mathrm{cm^2\,s^{-1}}$  with 80% of the probe freely mobile  $^{17}$ . In contrast, our FPR measurements clearly demonstrated that wheat-germ agglutinin, as well as peanut agglutinin, were completely immobile on both apical and basal membranes. It is thus unnecessary to postulate a diffusion barrier for the maintenance of the asymmetrical distribution of these probes.

The monolayers can be dispersed into single-cell suspensions by chelation of divalent cations, which has been shown to disrupt tight junction filaments in epithelia<sup>4,6,8,9,11</sup>. When this is done after first labelling one side of the monolayer with a lectin, the label spreads over the entire surface of the cell. After spreading, however, FPR measurements show that the probe is still completely immobile with respect to diffusion. Lectin binding sites maintain their relative positions during the spreading and do not inter-mix. Thus, the movement of the lectin while spreading over the entire cell surface after disruption of the monolayer apparently does not involve diffusion.

#### Lipid probes

We next investigated the behaviour of several fluorescent lipophilic probes introduced exogenously to the cell membranes. These probes (see Fig. 2) fell into two groups with respect to their labelling patterns: those which penetrated the tight junction (dilC<sub>n</sub> for n = 14, 16, 18, 20 and AFC<sub>12</sub>), and those which did not penetrate the tight junction (NBD-PC and AFC<sub>16</sub>). An example of domes labelled with AFC<sub>16</sub> is shown in Fig. 1b, where the scalloped pattern due to one-sided labelling is evident. In contrast, Fig. 1d shows a dome labelled with dilC<sub>16</sub>, which labels the entire cell membrane. As was the case with the lectins, all the non-penetrating lipid probes spread over the entire cell surface when the cell monolayer was disrupted by chelation of divalent cations.

We were also able to observe directly diffusion of the diIC<sub>n</sub> probes through the tight junction. By carefully manipulating the x-y position of the microscope stage, we manoeuvred a single cell (labelled with one of the diIC<sub>n</sub> probes) on the side of a dome (as in Fig. 1d) under an intense, focused laser beam so that all the fluoresence from either the apical or basolateral surface was bleached. Then, under normal fluorescence illumination, we observed fluorescence returning to the bleached membrane due to diffusion from the unbleached part of the cell on the other side of the tight junction. The fluorescence was replenished in a few minutes, which is as expected from the measured diffusion coefficient (Table 1). If the entire cell was bleached, no replenishment occurred. There was no transfer of the probe from neighbouring cells.

As the barrier to penetration between apical and basolateral membranes seems to occur at the tight junction, we tested whether epithelial cell lines having different permeability characteristics for aqueous solutes would exhibit different labelling patterns with the lipophilic probes. In many cases, 'leakier' epithelia have less extensive fibrillar networks forming the tight junction than 'tight' epithelia'. We found the labelling patterns for the probes in Fig. 2 to be identical in A6 cells (tight epithelium: trans-epithelial resistance =  $5,000~\Omega~cm^2$ ), MDCK cells (leaky epithelium: resistance =  $100~\Omega~cm^2$ ) and LLC-PK<sub>1</sub> cells (intermediate: resistance =  $400~\Omega~cm^2$ ) and LLC-PK<sub>1</sub> cells (intermediate: nesistance =  $400~\Omega~cm^2$ )

A more quantitative measure of the distribution of the fluorescent probes was obtained by measuring fluorescence intensities from apical and basal membranes separately on individual cells. The focused laser beam was used to excite fluorescence from a small spot (as in the FPR measurements) as the microscope focus was slowly scanned through the centre of a cell. A peak of fluorescence appeared, first as the apical, then as the basal membrane passed through focus (Fig. 3a). Figure 3b shows the time dependence of the fluorescence distribution thus measured for AFC<sub>16</sub>. This probe clearly does not penetrate significantly from apical to basal membrane, or vice versa, over time periods of a least 2h. AFC<sub>12</sub>, on the other hand, distributes

Table 1 Lateral diffusion coefficients of lipid probes in A6 cell membranes

Probe	Apical	Basal	Pass tight junctions
diIC14	$9.7 \pm 3.6 (17)$	$11.9 \pm 2.3 (14)$	+
diIC <sub>16</sub>	$7.9 \pm 3.4 (18)$	$10.2 \pm 5.6 (19)$	+
AFC <sub>12</sub>	$13.3 \pm 4.6 (10)$	$11.2 \pm 3.2 (9)$	+
AFC <sub>16</sub>	$4.2 \pm 1.8 (18)$	ND	
NBD-PC	$2.9 \pm 1.9 (33)$	$4.2 \pm 1.7$ (28)	une.

Values shown are the mean lateral diffusion coefficient  $(D)\pm s.d.$   $(\times 10^9 \text{ cm}^2 \text{ s}^{-1})$ . The number of cells measured is shown in parentheses. ND, not determined. The values for D are not corrected for the non-planar membrane geometry due to the presence of microvilli, which probably accounts at least in part for the higher values usually obtained on the basal membranes, which are non-villous.

so that  $\sim 30\%$  of the fluorescence finally localizes on the apical membrane, regardless of whether the apical or basal membrane was labelled initially (Fig. 3c). In addition, the distribution of AFC<sub>12</sub> is temperature dependent, with no passage from apical to basal membranes occurring if the cells are kept below  $10^{\circ}\text{C}$ —this cannot be explained by a low temperature immobilization of AFC<sub>12</sub>, as FPR measurements at this temperature showed that AFC<sub>12</sub> was still free to diffuse, although at a rather slower rate (data not shown).

The time course of the AFC $_{12}$  distribution has another curious feature. Within minutes after labelling the apical membrane, the probe redistributed so that 50-60% of the fluorescence localized on the apical membrane. Within the next 30-60 min this proportion gradually changed until only 25-30% of the fluorescence lay on the apical surface (Fig. 3c). This is not a trivial geometric effect due to the presence of more membrane on the basal surface. In fact the opposite is the case  $^{14}$ . The same apportioning of fluorescence occurred when the intact cell monolayer was detached and turned over and the basolateral membranes labelled initially (Fig. 3c). In contrast, the diIC $_{16}$  maintains 50-60% of its fluorescence on the apical membrane

It is possible that the lipid compositions of the apical and basolateral membranes are different, and that  $AFC_{12}$  prefers to 'dissolve' or partition into the lipids of the basolateral membrane. This is plausible, as differences in lipid composition between apical and basolateral membranes of epithelia have been reported<sup>3,13,21-23</sup>. Another possibility is that the probe's fluorescence is partially quenched at the apical surface, perhaps, for example, by low pH. We have no evidence to exclude either possibility.

# Basis of selectivity of the tight junction barrier

The molecular basis for the selectivity of the tight junction barrier to penetration of lipid probes is of primary importance both because of what it may reveal about the structure of the tight junction itself, and because of the implication that it may permit the cell to maintain different lipid compositions on the apical as opposed to the basolateral membranes. From the structures shown in Fig. 2, it is evident that molecular charge cannot be the sole determining factor, as there are positively and negatively charged probes which do penetrate (diIC, and AFC<sub>12</sub>), and negatively charged and uncharged probes which do not penetrate (AFC<sub>16</sub> and NBD-PC) the tight junction. The degree of partition of the probe between aqueous and membrane phases is also probably not important in determining whether the probe penetrates the tight junction. AFC12 and NBD-PC are the two probes with the highest aqueous phase partitioning, but they exhibit opposite behaviour with respect to passing through the tight junction, as do AFC<sub>16</sub> and the diIC<sub>n</sub>, which partition least in the aqueous phase.

It is interesting that  $AFC_{12}$  and  $AFC_{16}$ , which differ only in fatty acyl chain length, show opposite behaviour regarding penetration of the tight junction, which may indicate that interactions in the hydrophobic region of the membrane are important. In this regard, Table 1 shows that the lateral diffusion coefficients of the lipid probes are predictive of whether or not the probe penetrates the tight junction: all probes that can pass through the tight junction have lateral diffusion coefficients greater than  $\sim 8 \times 10^{-9}$  cm<sup>2</sup> s<sup>-1</sup>, whereas all those that are incapable of penetrating the junction have lateral diffusion coefficients  $< 4 \times 10^{-9}$  cm<sup>2</sup> s<sup>-1</sup>. Apparently, the two classes of lipid probes interact with the lipid bilayer in significantly different ways, as reflected by their lateral diffusion coefficients. This difference may provide the basis for whether a probe can penetrate the tight junction or not.

In view of the possibility that the two classes of lipid probes interact differently with the cell membrane, it is important to assess whether the probes are in fact inserted into the membrane lipid bilayer. From the molecular structures in Fig. 2 one would expect, on energetic grounds, insertion of the hydrocarbon chains into the membrane bilayer. On the other hand, it is

conceivable that a probe may form micellar structures which adhere to the cell surface and prevent true incorporation of the probe into the membrane. We consider this unlikely for several reasons. First, the measured diffusion coefficients are all in the range observed for lipid-like molecules in cell membranes<sup>24–29</sup>. In addition, the conjugated bridge of dilC<sub>18</sub> has been shown to be aligned parallel to the plane of the membrane when the probe labels erythrocyte ghosts, exactly as expected if the hydrocarbon tails are inserted into the membrane bilayer<sup>30</sup>. Finally, our fluorescence intensity and spectral measurements have shown that the probes are in a much more hydrophobic environment when labelling cells than when dispersed in aqueous media<sup>31</sup>, so that the possibility of probe micelles adhering to the cell surface is unlikely.

We feel that a possible basis for the observed selectivity of the tight junction lies in which leaflet of the membrane bilayer is occupied by a given probe; those probes which label the outer leaflet only do not pass through the tight junction, whereas those which can 'flip-flop' to the inner leaflet do pass through it. Phospholipids have been shown to flip-flop between membrane leaflets at very low rates in bilayer membranes <sup>32-34</sup>, and it seems reasonable to assume that NBD-PC behaves similarly. The smaller polar 'head group' region of the diIC<sub>n</sub> may allow it to pass more rapidly between inner and outer membrane leaflets, and the shorter acyl chain of AFC<sub>12</sub> relative to AFC<sub>16</sub> may facilitate its flip-flop, a process which is inhibited at low temperature.

Experimental evidence in support of this hypothesis has come from measuring the accessibility of the various membrane-bound probes to quenching from outside the membrane<sup>31</sup>. Using iodide to quench diIC<sub>16</sub> fluorescence and anti-fluorescein antibodies to quench AFC<sub>12</sub> and AFC<sub>16</sub> fluorescence, our data show that (1) diIC<sub>16</sub> seems to have access to both leaflets of phospholipid vesicle membranes; (2) AFC<sub>16</sub> is present almost exclusively in the outer membrane leaflet of labelled cells; and (3) AFC<sub>12</sub> can 'flip-flop' between membrane leaflets at 20 °C, but not at 5 °C. These results imply that the tight junction may form a barrier to passage of lipids only in the outer membrane leaflet. Thus, differences in lipid composition between apical and basolateral membranes could reflect differences in the compositions of the outer monolayer lipids.

#### Conclusion

We have studied the mechanism of maintenance of cellular asymmetry in epithelial cells grown in culture by directly observing whether fluorescent probes applied to either the apical or basolateral membranes spread to the unlabelled surface. Lectins which were bound to either the apical or basolateral membrane remained segregated there and were immobile with respect to lateral diffusion in the membrane. Some lipid probes introduced exogenously into the membrane were able to penetrate to the unlabelled side of the cell monolayer, whereas other lipid probes were not. All lipid probes were freely mobile in the membrane, although those which were able to spread over the entire cell had lateral diffusion coefficients at least twofold greater than those which could not. The barrier to spreading of the probes to the unlabelled surface was at the region of the tight junction. Chelation of divalent cations, which disperses the monolayer and disrupts tight junction filaments, allowed spreading of all the impermeant probes over the cell surface, although in the case of the lectins the spreading apparently did not involve free diffusion. The selectivity of the tight junction region to passage of the lipid probes was identical in monolayers of epithelial cell lines having markedly different 'leakiness' to aqueous solutes.

These results directly demonstrate that the region of the tight junction can act as a barrier to lateral diffusion of membrane constituents as small as lipids, potentially enabling epithelia to segregate at least some lipids to the apical or basolateral membrane and thus maintain an asymmetric lipid distribution. Fluorescence quenching experiments support the hypothesis that the lipid probes that have access to the inner leaflet of the

cell bilayer are capable of passing the tight junction, but those present exclusively in the outer leaflet are blocked by the tight

# Probable optical counterpart of a y-ray burster

Bradley E. Schaefer

Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

I describe here  $1.6 \times 10^7$  s (over half a year) of optical monitoring of three γ-ray burst positions using the collection of archival plates at the Harvard College Observatory. The search has uncovered the probable optical counterpart for the 19 November 1978  $\gamma$ -ray burster on a blue emulsion plate exposed in 1928. The optical flash observed on the 1928 plate has  $m_B \sim 3$ , for an assumed duration of 1 s. Optical searches indicate that the absolute magnitude of the  $\gamma$ -ray burst system at quiescence is fainter than 13. A recurrence rate of  $\sim 10^{-7.5}$  s<sup>-1</sup> is found from the  $\gamma$ -ray and optical data. A recurrence rate this high rules out any model which uses a collision between a neutron star and an asteroid-like body as well as any model which requires accretion from the interstellar matter onto a neutron star.

Since the discovery of cosmic y-ray bursts1, there have been many observations of these phenomena2, but so far no celestial object has been positively identified with any y-ray burster at other than y-ray energies3-7. In order to make an identification, an interplanetary network of satellites with γ-ray detectors has been established, so as to locate the direction of the  $\gamma$ -ray burst by triangulation<sup>2,3</sup>. Although this network has determined error boxes ~1 arc min in radius for several bursters<sup>3,8-11</sup>, no convincing optical<sup>3,12,13</sup>, radio<sup>14</sup> or X-ray<sup>10,15</sup> counterparts have been proposed.

Grindlay, Wright and McCrosky<sup>7</sup> have shown that a simple extrapolation of the observed y-ray spectrum implies that the sources would be optical flares with  $m_v \sim 0$ . This failure to detect optical flashes from two  $\gamma$ -ray bursts in the early 1970s allowed them to set limits on the brightness of the two events as  $m_{\rm v} > 3.0$  and 3.8 mag for an assumed duration of 1 s. The advantage of their work over that reported here is that a  $\gamma$ -ray burst was seen during their exposure.

Both theoretical and observational arguments suggest that  $\gamma$ -ray bursters are recurring phenomena. Jennings and White<sup>16</sup> use the observed  $\log N(>S) - \log S$  relation to deduce that the  $\gamma$ -ray recurrence rate must be  $>10^{-12} \, \mathrm{s}^{-1}$  per burster. For thermonuclear flash models<sup>17</sup>, the recurrence rate is predicted to

be between  $10^{-10}$  and  $10^{-7} \, \mathrm{s}^{-1}$ . The observational argument is based on several bursts, closely spaced in time, which seem to have identical positions<sup>18-20</sup>.

I have carried out a search of three precisely known  $\gamma$ -ray burst positions<sup>8-10</sup> on plates in the archival collection of Harvard College Observatory (see Table 1). On one of the plates for the 19 November 1978 field<sup>10</sup>, a new 10-mag star appears in the γ-ray error box. The plate is MF12559 taken on 17 November 1928 in South Africa. It is the fourth of six identical 45-min exposures taken in succession. Figure 1 is a reproduction of the third and fourth plates in the series. The 'new' star does not appear on any of the other five plates (all of which have a limiting magnitude of  $\sim 15$ ).

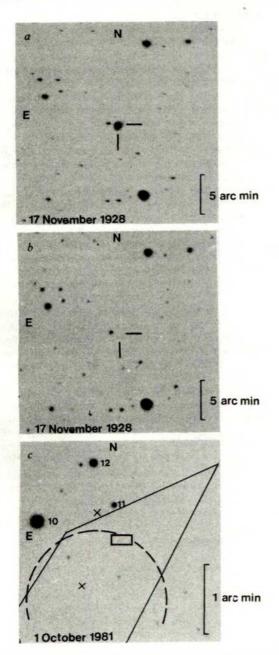

Microdensitometry provides strong evidence that the 'new' star image was formed by a brief flash of light which came through the telescope. The images on the fourth plate are trailed by 17 arcs, but the image of the 'new' star is not noticeably trailed, as would be expected if it were a short (≤10 min) optical flash. Figure 2 shows the profiles of the burst image and of two nearby normal star images in a direction perpendicular to the trailing. The asymmetry is due to coma, which implies that the burst image must have been formed by light that passed through the telescope optics and that plate defects and light leaks are not a possible explanation for the burster candidate. The profiles of normal stars as well as the candidate show a break at ~110 µm. which is further confirmation that the light that formed the burst image followed the same path as normal starlight.

The slope of the burst image profile in Fig. 2 is less than the slope of a normal star profile, which can be attributed to the failure of the law of reciprocity in photographic emulsions. In the relevant range of radial distances (r), the intensity (I) of light that reaches the plate will fall off as  $r^{-\eta}$  where  $\eta$  is some constant<sup>21-23</sup>. According to Schwarzschild's law of reciprocity failure  $^{24-26}$ , the photographic density (D) is proportional to  $I^{a}T$ , where q is a function of the duration of exposure (T). Thus and the slope on a log D versus log r plot is  $(-\eta q)$ . For a short flash, q is  $\leq 1$  (ref. 26). For a 45-min exposure, q is typically<sup>26</sup> 1.25, so that the normal star profile is expected to be steeper than the profile from a quick flash. Unfortunately, this argument cannot be made more quantitative because the emulsion type and developing conditions are unknown.

The 1928 image may have been formed by a 2-mag meteor viewed exactly head-on. The probability<sup>27</sup> of detecting a meteor in a y-ray error box on any plate used in this study is  $\sim 10^{-2}$ . Microdensitometry shows that the 1928 image is not trailed,

with an upper limit of 3 arcs trailing. The probability that a meteor will approach within this narrow tolerance of the head-on direction is  $10^{-8}$ . The joint probability of both seeing a meteor in a  $\gamma$ -ray burst error box and having that meteor appear head-on is  $\sim 10^{-10}$ .

The position of the image (1 h 16 min 25.8 s ± 0.6 s and  $-28^{\circ}$  51' 1.2" ± 2.1" measured with a Mann measuring machine) is inside the  $\gamma$ -ray error-box<sup>10</sup> but is not consistent with any observed radio sources<sup>14</sup> (see Fig. 1). The position is, however, inside the reported error-box of a possible (3.5 $\sigma$ ) X-ray source<sup>10</sup>. Recently, M. H. Liller took deep B and V 4-m plates of this region at CTIO. Both plates show faint stellar images ( $m \sim 23$ ) at the same location in the optical error box

**Fig. 1** Three views of the 19 November 1978 γ-ray burst field. a, Plate MF12559, with tick marks indicating the burst image. The burst image has a different shape from that of a normal star; a short flash is not trailed and has a more gradual fall off of density with distance from the centre of the image. b, Plate MF12558, which was taken 45 min before MF12559. c, A V plate taken by M. H. Liller on the 4-m telescope at CTIO. The image inside the  $2\sigma$  1928 optical positional error rectangle (centre) cannot be seen. The  $\gamma$ -ray error region 10 (solid lines) and possible X-ray error circle 10 (dashed lines) are also shown. Radio sources 14 are indicated with crosses. Three stars are numbered as in ref. 12.

Table 1 Exposure versus burst limiting magnitude

Limiting mag.	Hours of exposure which reach the limiting mag						
for detecting a 1 s burst	19 November 1978	5 March 1979	6 April 1979	Total			
3.0- 3.9	671	2,270	1,509	4,450			
4.0- 4.9	635	2,148	1,422	4,205			
5.0- 5.9	560	1,716	1,198	3,474			
6.0- 6.9	407	961	710	2,078			
7.0- 7.9	289	373	269	931			
8.0- 8.9	174	149	71	394			
9.0- 9.9	96	26	23	145			
10.0-10.9	34	1	7	42			

(1 h 16 min 25.99 s  $\pm$  0.02 s and  $-28^{\circ}$  51' 2.3"  $\pm$  0.3", 1950.0). Using a PDS microdensitometer, I find the images to be 3.2 $\sigma$  and 4.9 $\sigma$  above noise for the B and V plates respectively. A search by G. R. Ricker (personal communication) has, however, failed to locate this star with a CCD camera (the MASCOT) on the McGraw-Hill 1.3-m telescope ( $m \ge 24$  at  $2\sigma$  for 4,000-7,000 Å). Because of the uncertain thresholds and different band-passes, the question of the reality of this stellar image is not yet established. Deeper searches with the MASCOT have been carried out and the data are being analysed.

The magnitude of the image on the 1928 Harvard plate is uncertain because the profile of the burst image differs from a comparison star's profile. Exact modelling is impossible because the plate characteristics and burst duration are unknown. However, a reasonable model shows  $m_{\rm B} \sim 3$  for a burst lasting 1 s, which corresponds to a time-integrated flux of  $4\times 10^{-7}\,{\rm erg}\,{\rm cm}^{-2}$  above the atmosphere<sup>27</sup>. Assuming that the 1928 and 1978 bursts were similar,  $L_{\gamma}(>30~{\rm keV})/L_{\rm opt}(B~{\rm band})$  is 800 and the energy flux density is proportional to  $\nu^{0.6}$ .

Three other plates show density enhancements in the  $\gamma$ -ray burst error regions. A plate exposed in 1948 shows a 'new' star in the 19 November 1978 optical error box, and two plates (from 1932 and 1936) show 'new' stars in the 6 April 1979  $\gamma$ -ray error box. Because these three images are near the limiting magnitude of their respective plates a detailed analysis of the image profile is impossible.

Table 2 summarizes the characteristics and total exposure for the seven series of plates used in this study. For each plate, I estimated the magnitude of the faintest star image detectable. Burst-limiting magnitude' for each plate was derived from the known exposure times, an assumed burst duration, an approximate knowledge of the reciprocity failure, and the stellar limiting magnitude. The burst-limiting magnitude indicates how bright an optical flash of given duration must be to ensure detection on a given plate. An optical flash inside the nebulosity of N49 would be harder to detect, so the 'burst limiting magnitude' should be decreased by up to 1 or 2 mag for the 5 March 1979 field. I assume that the optical burst lasts 1 s as this is comparable to the durations of  $\gamma$ -ray bursts. Table 1 shows the total exposure for each of the three  $\gamma$ -ray positions that could lead to the detection of a burst of a given magnitude.

The steady optical flux from the burster can severely limit the types of stellar components which can be in the burster system. The CTIO 4-m plates of Liller indicate that the quiescent optical counterpart is fainter than ~23 mag. Jennings and White 16 show that the γ-ray bursters are probably not extragalactic nor are they distributed in a halo around our Galaxy. They deduce that the most likely distribution of γ-ray bursters is a disk population with a scale height of ~400 pc. In this case, the distance to the 19 November 1978 burster must be ≤1 kpc, because of its position near the south galactic pole. The limits on both the apparent magnitude and the distance yield a lower limit of 13 mag for the burster's absolute magnitude. Only three known classes of stars (white dwarfs, neutron stars and late M main sequence stars) satisfy this limit, and hence could be components of the burster system. Furthermore, if the ~23 mag star on Liller's plate is the optical counterpart of the burster, then this cannot be a lone neutron star. This is because a lone neutron star has an absolute

Table 2 Characteristics of Harvard plates

Plate series	Aperture (cm)	Plate scale (arc s mm <sup>-1</sup> )	Dates	Total exposure (h)	Total no. of plates	Median limiting mag.	Median limiting mag. for 1 s burst
Α	61.0	60	1896-1950	68	¥ 50	16.5	8.2
AM/AX	3.8	600	1901-1953	2,689	2,465	14.1	5.8
В	20.3	179	1889-1948	198	414	15.3	8.1
Damon	4.1	580	1970-1979	75	50	15.2	6.9
MF	25.4	167	1918-1950	210	299	16.4	8.9
RB	7.6	391	1928-1950	1,210	857	14.8	6.5

magnitude >23 (assuming the neutron star radiates as a black body<sup>28</sup>), and would have to be placed at such a close distance as to violate the  $\log N$  (>S) -  $\log S$  observations. We note (D. O. Lamb, personal communication) that the class of y-ray burst models which invoke an energy supply internal to a neutron star<sup>29</sup> do not require that the neutron star have a companion.

The value for the burster recurrence rate can be estimated. (1) From detailed modelling of the log N(>S) - log S relation. Jennings and White<sup>16</sup> show that the recurrence rate must be between  $10^{-12}$  and  $10^{-1}$  s. (2) Let  $N_T$  be the total number of γ-ray burst sources which are accessible to near-Earth detectors with a threshold  $f_0$ , and let R be the number of  $\gamma$ -ray bursts observed with flux  $> f_0$  which arrive at Earth per second. The average recurrence rate will be just  $R/N_T$ .  $N_T$  must be greater than the total number  $(N_0)$  of non-overlapping error boxes determined for bursts with a flux greater than  $f_0$ . From the data base of Mazets and Golenetskii<sup>20</sup>, with  $f_0 \sim 10^{-6}$  erg cm<sup>-2</sup>,  $R \sim$  $10^{-5.8} \,\mathrm{s^{-1}}$  and  $N_{\mathrm{T}} > N_{\mathrm{0}} > 35$ , the recurrence rate must be  $<10^{-7.3}$  s<sup>-1</sup>. (3) With a total observing time of  $10^{7.3}$  s, the data from Mazets and Golenetskii<sup>20</sup> suggest two and possibly more cases of a  $\gamma$ -ray burster recurring. These cases suggest the burst

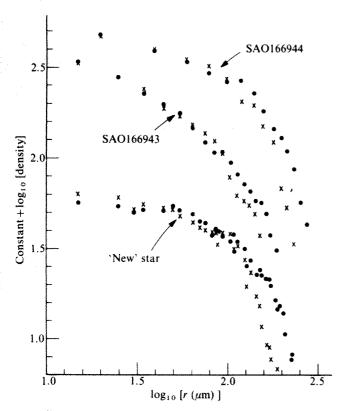

Fig. 2 Profiles along the north-south axis of the burst image and two nearby normal stars. The densities north (south) of the image centre are indicated with ×(•). The differences between the north and south profiles are due entirely to coma, because the scan direction is perpendicular to the direction of trailing. The profile of the burst image has been lowered by 0.6 in the logarithm of density for clarity. The zero of the density scale is set to the density of the sky background.

rate is  $\sim 10^{-7} \, \text{s}^{-1}$ . (4) One (and possibly as many as four) optical bursts were seen during a monitoring time of 10<sup>7.2</sup> s, which implies a recurrence rate of order  $10^{-7.2}$  s<sup>-1</sup>. From all the evidence, a reasonable estimate of the burster recurrence rate is  $\sim 10^{-7.5} \,\mathrm{s}^{-1}$  (one burst per year).

This high recurrence rate precludes the hypothesis where an asteroid (or comet) impacts onto a neutron star<sup>30</sup>, which predicts typical recurrence rates on the order of  $10^{-13}$  s<sup>-1</sup> (refs 31, 32). A popular class of models envisions a thermonuclear explosion on a neutron star surface. For a typical burst energy <sup>16</sup> of 10<sup>39</sup> erg and mass-to-energy conversion<sup>33</sup> of 10<sup>19</sup> erg g<sup>-1</sup>, the neutron star will need to accrete 10<sup>20</sup> g of fuel for each burst. To transfer this amount of mass every  $\sim 10^{7.5}$  s, the average accretion rate is many orders of magnitude higher than is obtainable by accretion from the interstellar medium alone. If this accretion rate remains constant, then a source 100 pc distant would imply a steady X-ray flux of  $\sim 10^{-10}$  erg s<sup>-1</sup> cm<sup>-2</sup>. Observations with the Einstein Observatory<sup>3</sup> have placed upper limits of  $\sim 10^{-12} \, \text{erg s}^{-1} \, \text{cm}^{-2}$  on the steady X-ray flux from the three  $\gamma$ -ray bursters listed in Table 1. If the thermonuclear explosion model and the physical values are correct, this discrepancy can be explained by assuming either that most of the accretion energy is not radiated in the X-ray or that the accretion is not steady.

Without the archival plates at Harvard College Observatory, this search would have been impossible. I acknowledge the use of facilities at the Harvard/Smithsonian Center for Astrophysics, Yale University, and Kitt Peak National Observatory. I thank H. V. Bradt, J. E. Grindlay, P. C. Joss, D. Q. Lamb, J. E. McClintock, and E. L. Wright for helpful conversations, also M. H. Liller for the two 4-m plates she took at CTIO and G. R. Ricker for the early communication of his MASCOT results. This work was supported in part by NASA grant NSG-7643.

# A four-hour orbital period of the X-ray burster 4U/MXB1636-53

Holger Pedersen\*, Jan van Paradijs† & Walter H. G. Lewin‡

\* European Southern Observatory, Karl Schwarzschildstrasse 2, D-8046 Garching, FRG

† Astronomical Institute, University of Amsterdam, Roetersstraat 15, 1018WB Amsterdam, The Netherlands † Department of Physics and Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

It has been generally accepted that X-ray burst sources and other non-bursting 'galactic bulge X-ray sources' are low-mass close binary systems (for a review see ref. 1). The companion stars of the transient burst sources Aql X-1 (= Aql MXB = 4U1908+00) and Cen X-4 (= XB1455-31) are of spectral types G7-K3V (ref. 2) and K3-7V (ref. 3), respectively. The companion of the non-bursting transient source A0620-00 is of spectral type K4-5V (refs 4, 5). If these stars fill their Roche lobe, which is likely, the orbital periods are in the range 5-8 h. There is some evidence from X-ray observations alone that the orbital period of Cen X-4 is ~8 h (ref. 6). From an analysis of their average optical properties, one of us (J.vP. ref. 7) estimated that the typical values of the companion star masses and orbital periods of this class of low-mass X-ray binaries are ~0.6  $M_{\odot}$  and ~6 h, respectively. The orbital period recently suggested for the burst source 4U/MXB1735-44 (ref. 8) is in accordance with this general picture. We here report variations in the persistent optical flux of 4U/MXB1636-53 which seem to vary periodically with a period near 4 h.

During June-August 1979 and 1980 extensive optical observations were made of the X-ray burst source 4U/MXB1636-53 (see refs 9, 10 for properties of the faint blue counterpart  $(B\sim18)$  of this source). Some of these observations were made simultaneously with the Japanese X-ray observatory Hakucho. Results on correlated optical/X-ray bursts and other optical bursts will be reported elsewhere  $^{11,12}$ .

The observations were made with the Danish 1.5-m telescope at the European Southern Observatory (ESO) at La Silla. During the 1980 observations a double-channel photometer was used with no filter. The combination of atmospheric transmission, optics and photomultiplier sensitivity defines a 'white light' passband with an effective wavelength of  $\sim 4,300 \, \text{Å}$  and a full width at half-maximum of  $\sim 1,900 \, \text{Å}$ . The telescope was guided using an autoguiding system which kept the star centred to  $\leq 1$  arc s. In the channel used for measurements of 4U/MXB1636-53, a 5 arc s diaphragm was used. The reference channel which used a 20 arc s diaphragm was set on a star  $\sim 3$  mag brighter a few arc minutes away from the main channel. The ratio between stellar signal and sky brightness was similar for the two channels (1.5 and  $\sim 1.2$ , respectively).

We observed 4U/MXB1636-53 on 11-13 July 1980. The data trains span  $\approx 7$  h each night. The nights were dark, photometric and the seeing was less than 2 arc s. Figure 1 shows the observed count rates binned into 512-s time slots, together with similar data for the reference channel. The latter is constant to within  $\pm 2\%$  throughout each night. Clearly, however, the persistent optical flux of 4U/MXB1636-53 is varying. As the ratio of stellar to sky signal is approximately equal in the two channels, this variation cannot be due to changes in the sky brightness. Such changes would result in a similar variation (approximately same percentage) in the reference signal and that is not observed. Furthermore, the relatively good seeing in combination with the 5 arc s diaphragm and the high-quality autoguiding of the star (see above), exclude the possibility that

the variation is due to variable signal contamination by a star of similar brightness about 7 arcs north of 4U/MXB1636-53. The data suggest that the variability may be periodic. Five broad maxima occur in the optical brightness near 11 July, 0200 and 0615 UT, 12 July, 0100 and 0430 UT and near 13 July, 0315 UT. These maxima are consistent with a single period of approximately 4 h.

To establish a more accurate period, we have folded the data with trial periods between 2 and 6 h, and searched for periods where  $\chi^2$  of the data points, relative to the average curve (divided into 20 phase bins), showed a minimum. Before folding the data, the overall nightly average counting rate was subtracted. Three possible periods turned up (see Fig. 2) 3.28 $\pm$ 0.05 h, 3.78 $\pm$ 0.05 h and 4.42 $\pm$ 0.05 h, corresponding to 15, 13, and 11 cycles between the maxima on 11 July, 0200 UT and 13 July, 0315 UT, respectively. Figure 3 shows the folded count rates (as described above) for the period of 3.78 h. The amplitude is ~25% of the average signal (sky background subtracted).

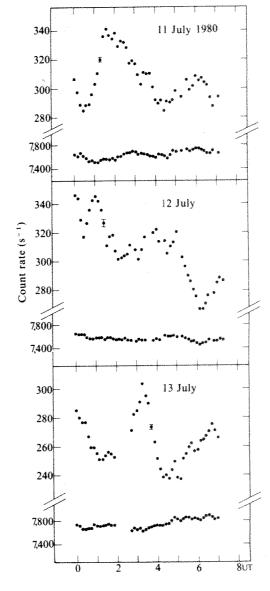

Fig. 1 Count rates, including sky background, for 4U/MXB1636-53 and the reference star (upper and lower set of points in each panel) as observed on 11, 12 and 13 July 1980. Each point represents the average of 10 integrations of 51.2s each. Typical mean errors on the averages of these 10 values are indicated in the figure by one error bar in each panel. The error bars in the reference star data have approximately the size of the dots. The blue magnitude corresponding to the average sky-corrected counting rate is  $B \sim 18.5$ .

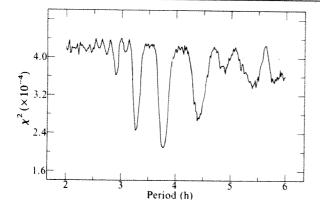

Fig. 2  $\chi^2$  (relative to the average folded curve divided into 20 phase bins) as a function of the folding period. The three deep minima correspond to periods of 3.28, 3.78 and 4.42 h, respectively.

We observed 4U/MXB1636-53 again on 1 August 1981, 0140 UT until 0445 UT, again using the Danish 1.5-m telescope. The photometer used was operated as a single channel instrument. The detector was an RCA C31034A photomultiplier tube illuminated through a 5-mm liquid CuSO<sub>4</sub> filter. A 9 arc s diaphragm was used. The observations were repeatedly interrupted to measure the sky background and the brightness of two nearby companion stars. Photometric conditions were good, with seeing of less than 2 arc s. To avoid any possible contamination of the signal by light from the star  $\sim$ 7 arc s north of 4U/MXB1636-53, the centre of the diaphragm was placed about 1.5 arc s south of 4U/MXB1636-53.

Figure 4 shows the ratio of the counting rates (sky background subtracted) of 4U/MXB1636-53 to one of the reference stars. A smooth modulation of the brightness of 4U/MXB1636-53 is clearly visible, with a shape that is consistent with the average variation found in the 1980 observations (see Fig. 3). Clearly the data are insufficient to decide between the above three allowed time periods.

If any of these three possible periods is the orbital period of 4U/MXB1636-53, then the mass of its companion star can be estimated if the following assumptions are made (see refs 13, 14). (1) The companion star fills its Roche lobe. This is likely in view of the rate of mass transfer needed to power the persistent X-ray emission of 4U/MXB1636-53. (2) The companion star is on the main sequence.

The orbital period, P, is then uniquely determined by the mass  $M_c$  of the companion star according to the relation  $P = 3.14 \times 10^4 \times (M_c/M_\odot)$  s. Using this relation and the above

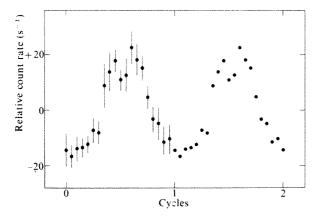

Fig. 3 Average light curve of 4U/MXB1636-53 during 1980, 11, 12 and 13 July, for a folding period of 3.78 h. Before folding the data, the average counting rate, as observed during each night, has been subtracted. The error bars indicate the mean errors of the average values in the phase bins. For convenience the same data have been plotted twice.

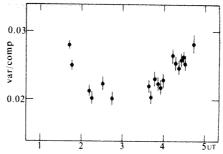

Fig. 4 Ratio of the counting rates (sky-subtracted) of 4U/MXB1636-53 (var) to that of one of the comparison stars (comp). The corresponding ratio of the two comparison stars used is constant to within  $\pm 2\%$ . The data were taken on 1 August 1981.

period of  $\sim$ 4 h, we find a mass of  $\sim$ 0.4 $M_{\odot}$  (corresponding to an M0 V star) for the companion of 4U/MXB1636-53.

If we identify the period in the optical brightness variations of 4U/MXB1636-53 with the binary period, a major deviation from axial symmetry must be present in the system. Within the framework of the low-mass X-ray binary model we can exclude the following possible causes of the brightness modulation.

(1) Eclipses of the accretion disk by the companion star (assumed to fill its Roche lobe). They would result in a much narrower minimum in the light curve than is actually observed (see Fig. 3). (2) As the companion star contributes only of the order of 1% or less to the total optical brightness of the system<sup>7</sup>, changes in its visibility cannot explain the observed brightness modulation either. In particular double-wave ellipsoidal variations (with a corresponding period near 8 h) can be excluded. (3) The modulation cannot be the result of eclipses of a hot spot (where matter is injected into the disk), as observed for some cataclysmic variables14. The luminosity of such a hot spot is expected to be approximately independent of the nature of the compact star at the centre of the disk (white dwarf or neutron star). Because the optical luminosity of low-mass X-ray binaries is a factor of  $\sim 10^2$  larger than that of cataclysmic variables this spot would therefore only contribute of the order of 1% of the total optical brightness of the system.

The disk thickness (seen from the compact object), estimated on the basis of the average optical and UV properties, is ≥6° (ref. 7). In a binary system with a mass ratio q = 0.3 and total disk thickness ≥6°, the solid angle subtended by the non-shielded part of the companion star (as seen from the compact object) is -30% of that of the disk. Thus, if the accretion disk in 4U/MXB1636-53 has a total thickness of about 6° and is not thicker, a significant contribution to the optical brightness variation might be due to the heating by X rays of the companion star and the observed modulation could then be due to the orbital motion of the companion star. It may be that the accretion disk in this system is much thicker than 6° (see the suggestion in ref. 15). For total disk thickness of  $\sim 30^{\circ}$  the optical companion would lie entirely in the X-ray shadow of the disk and this could naturally explain why X-ray eclipses are, in general, not observed in these systems<sup>1,15</sup>. If such a thick disk is present in 4U/MXB1636-53, we suggest that this disk is not axially symmetric, perhaps being thicker where matter is injected into the disk. A similar suggestion has been made for the source 2A1822-37 (refs 16, 17). The brightness modulation could then be the result of the azimuthal dependence of the surface brightness of the disk in combination with the phase dependence of the angle at which the different parts of the disk are viewed.

If this is the case and also if the observed modulation is due to X-ray heating of the companion, we expect a similar modulation with the orbital period of the average ratio of optical to X-ray burst energies. Clearly we then expect that the observed delay between optical and X-ray bursts will also vary with the ~4 h period.

# Intrinsic variations of the double quasar 0957+56 AB

#### C. Lloyd

Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, East Sussex BN27 1RP, UK

Spectroscopic evidence strongly suggests that the two quasars 0957+56 A and B are images produced by the gravitational lensing of a single distant quasar (at z=1.41) by a giant elliptical galaxy and its attendant cluster (at z=0.36)<sup>1-6</sup>. It has also been suggested that the quasar is an intrinsic variable 7.8. I report observations that show a variation of ~1 mag in both components and behaviour typical of intrinsically variable quasars with similar radio structure. The near constancy of the magnitude difference between the components at several epochs despite overall variations favours all the variations being intrinsic to the quasar and also supports the gravitational lens hypothesis. Recent variations of component B1 limit the time delay between the images to between 2 and 24 yr.

In an analysis of the imaging of the double quasar Young et al.5 suggested that three images are formed. Two images A and B1 lie 5 and 1 arc s respectively on either side of a faint elliptical galaxy and correspond to the objects for which photometry and spectrophotometry have been reported. The weak third image B2 is so far undetected and thought to be coincident with the galaxy. Photometry of components A and B1 were obtained from the Palomar Observatory Sky Survey (POSS) and the 26-inch refractor at Herstmonceux. The new photographic B band observations are combined with magnitude differences from photometry and spectrophotometry given by various authors: despite the variety of systems used the observations should be directly comparable. Details of the reductions are given in Fig. 1 legend.

Figure 1 shows the light curve of the double quasar between April 1979 and June 1981. The Herstmonceux photometry is consistent with component A being constant and Young et al. also found A constant before the Herstmonceux observations at B = 17.6. The observations of component B1 are in excellent agreement and show that from April to December 1979 both components were constant with  $B1 \sim 0.35$  mag fainter than A. Between December 1979 and June 1980 B1 brightened by ~0.45 mag and between June 1980 and June 1981 it faded slightly. If this downward trend continues component B1 will return to its previous luminosity by ~April 1982. Notice that the rise and decline do not have the same slope.

Although all the observations of component B1 are to some extent contaminated by the elliptical galaxy and the weak third image B2 the effects are probably negligible. The contribution from the galaxy decreases rapidly towards the blue and in the B band is  $\leq 5\%$  (ref. 4). This small additional flux will be essentially constant for all observations employing an aperture of a few arc seconds. The magnitude differences from the spectrophotometry refer to the continua while the B band photometry includes the C III]  $\lambda$  1,909 line. However the line contributes ≤5% and will be essentially the same for both components and the line strength is not expected to vary9. The third image B2 contributes ≤5% to B1 so its effect will also be negligible<sup>5</sup>.

As for longer term changes the double quasar appears on adjacent POSS plates taken in February 1953 and January 1955. From the O-plates the B mag of component A is 16.9 and  $16.6\pm0.2$  on the two dates respectively, with component B1 = 0.3 mag fainter on both occasions. So both components were -1 mag brighter and the magnitude difference about same as in 1979. From archival plates taken in 1902, 1903 and 1915 Keel<sup>8</sup> finds both components ~0.5 mag brighter than at present and the magnitude difference is  $\approx 0.5$ .

The near constancy of the difference despite an overall 1 mag variation strongly suggests that one component follows the other as would be expected with intrinsic variations and that the time delay is short compared with the intervals between epochs. 0956+57AB can be compared with quasars of similar radio structure as a guide to what optically variability might be expected. Similar objects dominated by an extended steep radio spectrum source<sup>10</sup> undergo slow variations with occasional abrupt changes of slope and periods of constancy. This is seen in Fig. 1. The maximum amplitude that might be expected is 1-1.5 mag (unpublished data) which is well in line with that so far observed.

The photometry does allow some constraint to be placed on difference in light travel times. Long delays are excluded by both the POSS and the 1979 plates showing  $\Delta m = 0.3$ . So  $\Delta t < 24$  yr. From the photometry in Fig. 1, if A follows B1 then  $\Delta t > 1.5$  yr. However, if B1 follows A then  $\Delta t > 2$  yr. This will be increased to ~3 yr if B1 returns to its previous luminosity at the current rate of decline. In a recent analysis Young et al. s gave the time delay  $\Delta t < 6$  yr with component A preceding B1. Combining this with the minimum delay from the discussion above gives a delay  $2 < \Delta t < 6$  yr. If the sense of the delay is correct then the feature recently observed in the light curve of component B1 has already passed in component A and 2 yr at constant luminosity are still to come for B1. The third image B2 is very faint and its effect on the time delays involving B1 will be negligible<sup>5</sup>.

An alternative cause of luminosity variations may be changes within the gravitational lens<sup>11-13</sup>. According to Canizares<sup>14</sup> as an individual star passes through the beam from a quasar the luminosity will be increased typically by several magnitudes. The time scale for this variation is  $\sim 15$  yr but depends on the size of the beam, the mass of the star and the velocities involved. In the case of the double quasar Gott<sup>15</sup> considers that very low mass stars will dominate and produce variations in 1-40 yr. On this basis component B1 is expected to be the more variable as it is seen through regions of higher stellar density than component A at ~5 kpc from the centre of the galaxy. However, Young<sup>16</sup> considered the effects of very low mass stars to be virtually undetectable and suggested that even with a normal stellar population there will be a sufficient number of stars in the beam for the effects to overlap. This means component B1 should vary continuously by up to 50% over 100 yr while component A undergoes the occasional ~15-yr outburst. According to Gott<sup>15</sup> component B1 should generally be brighter than  $I_{B1} = 0.75 I_{A}$  $(\Delta m \le 0.3)$  while Young<sup>16</sup> predicted substantial variation about this value. Both appear to be at odds with the observations for on only one (1980) of the epochs, 1902, 1903, 1915 (Keel)<sup>8</sup>, 1953, 1955 (POSS), 1979, 1980 on which the double quasar has been observed has the ratio been substantially different from  $I_{\rm B} =$  $0.75 I_A (\Delta m = 0.3)$ . With a large beam size the ratio can be kept constant for ~50 yr but it is then impossible to duplicate the rapid changes recently observed. Conversely when the type of variations in Fig. 1 can be modelled the long-term variations are at odds with the prediction. Even in favourable conditions Young<sup>16</sup> considered the recent variations to be too large and too rapid to be due to the passage of stars through the beam. In conclusion the variations in the long and short term are inconsistent with those predicted for the passage of stars through the beam but are consistent with intrinsic variability.

I will make a final comment on the luminosity of the quasars involved in 0957+56AB and the other gravitational lens candidate 1115+080 ABC (ref. 17). If the amplifications of  $\sim 6$ for 0957+56A and ~14 for 1115+08A are correct then the luminosities of the unamplified quasar are  $M_B \sim -23.6$  and -24.4 respectively ( $H = 100 \text{ km s}^{-1} \text{ Mpc}^{-1}$ , q = 1). These are far in excess of the luminosities of Seyfert galaxies and seriously undermine the suggestion that all quasars are gravitationally lensed Seyfert galaxies<sup>18</sup>

Both components of the double quasar are variable by at least 1.0 mag and show behaviour typical of intrinsically variable quasars with extended radio structure. The near constancy of the difference between the two components at several epochs is contrary to what is expected if the variations are due to the

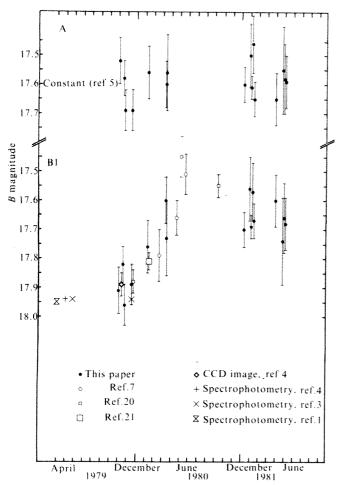

Fig. 1 The light curve of 0957 + 56A and B1 from April 1979 to June 1981. The diagram contains 16 new measurements of both components together with 12 differential measurements from various authors. For the Herstmonceux photometry unfiltered HaO emulsions were used which give magnitudes very close to the B band. Both components were reduced independently relative to a sequence of comparison stars. As no photoelectric sequence is available the relative magnitude scale was obtained through reference to two well calibrated fields from the Herstmonceux quasar monitoring programme <sup>19</sup>. The error in the relative magnitudes is ≤10% and this component is included in the error bars. The zero point of the B magnitude scale is taken as the mean value of component A which is defined as B = 17.6 (as given by Young et al.4) and has an uncertainty of ±0.1 mag. Differential measurements from photometry and spectrophotometry given by other authors are plotted on the assumption that component A is constant throughout this period. This is supported by Keel<sup>8</sup> and by Young et al.5 who find A constant between April 1979 and July 1980.

passage of stars through the beam. Recent photometry places a lower limit of 2 yr on the time delay between the components and if component B1 follows A as calculated by Young et al.5 then the feature observed in the light curve of B1 has already passed in component A. Analysis of archive plates should reveal more about long-term changes but the question of the time delay should be resolved by continued detailed monitoring.

I thank all those involved in obtaining plates, Paul Murdin and Ed Zuiderwijk for discussions and Bill Keel for material in advance of publication.

# First remote sensing of the plasmapause by terrestrial myriametric radiation

#### **Dyfrig Jones**

Space Plasma Physics Section, Atmospheric Sciences Division, British Antarctic Survey, NERC, Madingley Road, Cambridge CB3 0ET, UK

The Earth's plasmapause is a source of natural radio emission in the myriametric wavelength range ( $\lambda_{vac} \sim 10 \text{ km}$ ) and several mechanisms have been proposed for its generation. One such theory advocates the mode conversion of electrostatic waves to electromagnetic radiation by propagation through a radio window. The window properties are such that the escaping terrestrial myriametric radiation is beamed away from the magnetic equatorial plane at an angle which depends on the plasma parameters at the window. This property should allow myriametric radiation observed by spacecraft to be utilized for remote sensing of the plasmapause. An example derived from the satellite GEOS 1 is presented here in which a radial profile of cold plasma density is obtained for the first time by this technique. The method may also allow a better identification of those electrostatic modes existing in the mixture of hot and cold plasma components at the plasmapause and beyond.

Trapped non-thermal continuum (NTC) is used to describe broad-band radio noise at frequencies ≤40 kHz observed by spacecraft in the plasmatrough, the cavity of low-density plasma between the Earth's plasmasphere and magnetosheath1. Escaping NTC is noise at higher frequencies which propagates through the magnetosheath into the solar wind2. NTC is now widely believed to be produced not as a continuum, but as distinct beams of radiation, with different frequencies emanating from different, albeit possibly adjacent regions of the plasmapause<sup>2,3</sup>. After multiple reflections at the plasmatrough boundaries the beams from numerous sources are scattered and merge to produce the radio continuum. Myriametric describes the free space wavelength of the radio noise and brings the nomenclature in line with other planetary beamed emissions<sup>3</sup>.

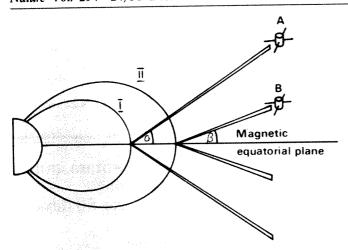

Fig. 1 Representation of the beaming of 30-kHz TMR away from the geomagnetic equatorial plane. The observation of the waves by satellite A allows the position of plasmapause I to be determined. If the observation is made on satellite B, the plasmapause will lie at location II.

The source of terrestrial myriametric radiation (TMR) seems to lie in electrostatic upper-hybrid-resonance (UHR) waves<sup>3</sup> which are observed to be most intense within ±1° of the geomagnetic Equator at and beyond the plasmapause in the morning sector<sup>7</sup>. Theories of TMR production mechanisms have been recently reviewed by Melrose<sup>6</sup>; the one considered here invokes the propagation of UHR wave energy through a radio window<sup>3,4</sup>. The window possesses unique properties in that the TMR will be left-hand polarized and beamed away from the geomagnetic equatorial plane at an angle dependent on the ratio  $f_{ce}/f_p$  at the window, where  $f_{ce}$  and  $f_{pe}$  are the electron cyclotron and plasma frequencies respectively3. These properties allow satellite observations of TMR far removed from the source region to be used to determine the radial profile of cold plasma density at the plasmapause. If the satellite later traverses the source region, in situ measurements should provide confirmation of the derived profile and information on the relationship between hot and cold plasma components at the plasmapause and beyond.

The term 'window' is used here to denote the phenomena whereby waves in one magnetoionic mode can penetrate through a region where, according to simple ray theory, they would be evanescent, and can emerge on the far side in a different magnetoionic mode (see ref. 8 for a recent review of

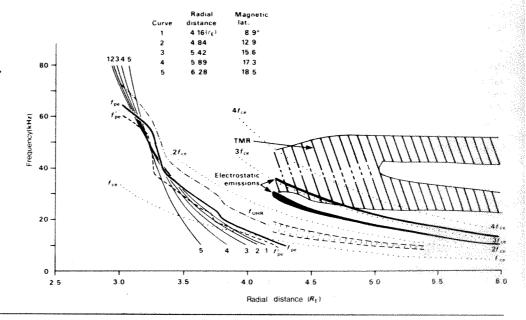

window theory). In the case of propagation of UHR-Z mode waves through a radio window to become left-hand polarized ordinary (L-O) waves, it may be shown that for  $f_{\rm ce} < f_{\rm pe}$ , the 6-dB window half-widths at the plasmapause for TMR frequencies are typically 1°-2°. Such narrow beams, together with the restricted latitudinal dimensions of the UHR source region, allow remote satellite observations of TMR to be utilized to determine the radial position of the window. Thus, because the frequency at which TMR exits from the window is  $f_{pe}$ , the plasma density  $N_e$ , being proportional to  $f_{pe}^2$ , may be determined. Figure 1 illustrates the technique by showing two possible positions, I and II. of the plasmapause. In position I, TMR at 30 kHz is beamed away from the geomagnetic equatorial plane3 at angle  $\alpha = \tan^{-1}(f_{ce}/f_{pe})^{1/2}$ , whereas if the plasmapause is in position II the same frequency would be beamed at a different angle  $\beta$  since  $f_{ce} \propto 1/R_0^3$  has changed,  $R_0$  being the radial distance of the source; the beamwidth in both cases is only 1°-2° and the beams will have mirror images about the equatorial plane. Satellite A, located at radial distance R and magnetic latitude  $\eta$ , will observe TMR source I, whose radial position  $R_0$  may be determined from the equation:

$$R_0^3 R^2 \sin^2 \eta / f_{\text{ceq}} - R_0^2 + 2R_0 R \cos \eta - R^2 \cos^2 \eta = 0$$
 (1)

where  $f_{\rm ceq}$  is the equatorial gyrofrequency at the Earth's surface. A more general expression exists for the case where the satellite and source are not in the same magnetic meridian plane. Similarly, satellite B observations would allow the source position to be determined when the plasmapause is in position II. Note that trapped NTC need not show any beaming effect with respect to the equatorial plane, because after multiple reflections one would expect the plasmatrough to be filled with NTC. However, escaping NTC which has not suffered reflections is synonymous with TMR and should show beaming<sup>2</sup>.

During the period 0200–0400 UT 4 March 1978, a very stable TMR pattern<sup>3</sup> was observed by the satellite GEOS 1 as it moved inbound from  $6.2R_{\rm E}$  to  $4.2R_{\rm E}$ . The satellite changed during that time only 5° long, with respect to a plasmapause source corotating with the Earth. From the way in which the signal intensity increased as the plasmapause was approached it is evident that the source and the satellite were close to being in the same meridian plane. The satellite magnetic latitude decreased nearly linearly from 18° to 8° over the above radial distance. Figure 2 shows a sketch of the TMR spectrogram (see ref. 3 for original) which, beyond  $5R_{\rm E}$  exhibits two bands, one in the region of 50 kHz and the other at lower frequencies; the bands merge into one at smaller radial distances. The variation in the upper and lower frequency limits of the lower band is due to the satellite

Fig. 2 Curves 1-5 show TMR theoretically visible to. GEOS 1 at the five positions shown in the inset table during the inbound leg on 4 March 1978 at ~0600LT. Also shown are the wave emissions seen by the satellite during this period. The hatched region is TMR, whereas the more intense narrow band emissions between gyroharmonics are electrostatic. The weaker emission between  $f_{ce}$  and  $2f_{ce}$  is linked to the cold upper hybrid frequency  $f_{UHR}$ as determined from remote sensing. The 'virtual' and 'real' plasmapause are depicted by  $f'_{pe}$  and  $f_{pe}$  respectively.

intersecting TMR beams of different frequencies during its inbound traverse3. The table in Fig. 2 shows five satellite locations at which equation (1) was applied assuming, in the first instance, that the whole frequency range 10-80 kHz was visible to GEOS 1. The corresponding source profiles are labelled 1-5 in Fig. 2, and it is immediately apparent that the five curves all intersect close to  $50 \, \text{kHz}$  at  $3.22 R_{\text{E}}$ . The significance of this is that if the plasma frequenc is  $50 \, \text{kHz}$  at  $3.22 R_{\text{E}}$ , the satellite should observe that frequency during the whole of its inward traverse from  $6.2R_{\rm E}$  to  $4.2R_{\rm E}$ , which indeed it does

By utilizing the spectrogram and a complete family of theoretical curves similar to 1-5 in Fig. 2, one can determine the source positions at other frequencies and hence obtain a radial profile of plasma density. For example, if at a given frequency and satellite position no TMR is observed, this indicates that the source does not lie on the corresponding theoretical profile, whereas if TMR is visible the source position for that frequency can be determined from the relevant curve. The radial plasma frequency profile constructed in this way for 4 March 1978 is labelled  $f'_{pe}$  in Fig. 2. A small correction to allow for wave refraction at the window has to be applied to this profile as equation (1) was derived assuming linear propagation. Ray tracing calculations indicate that  $\sim 0.08R_{\rm E}$  has to be added to the radial positions of the sources and thus the 'true' plasma frequency profile is shown labelled  $f_{pe}$ .

Figure 2 shows (dotted) the electron cyclotron frequency  $f_{ce}$ and its harmonics. The strongest natural emission band observed in the spectrogram lies between  $2f_{ce}$  and  $3f_{ce}$ , whereas the much weaker emission between  $f_{ce}$  and  $2f_{ce}$  is the one that links smoothly to the  $f_{\rm UHR}$  profile as calculated from  $f_{\rm UHR} = (f_{\rm pe}^2 + f_{\rm ce}^2)^{1/2}$ . Note that GEOS 1 was at magnetic latitudes greater than 8° when the spectrogram was recorded. Unfortunately, the satellite was subject to its end of orbit switch-off before it traversed the predicted source region and hence no direct in situ observations could be made on that particular pass. However, on the previous day, GEOS 1 remained in operation as the equatorial plane was crossed and the TMR observations, although themselves more limited in extent and more complicated in spectrum than on 4 March indicated that the plasmapause position was in approximately the same position. As for 4 March 1978, the strongest electrostatic emissions lay between  $2f_{ce}$  and  $3f_{ce}$  when the satellite was at magnetic latitudes  $\geq 3^{\circ}$ , but as the Equator was approached the weak emission between  $f_{ce}$  and  $2f_{ce}$  increased in intensity and became the most intense at the Equator. Therefore, from the indirect evidence on 4 March and the more direct evidence on 3 March, the cold UHR emission apparently dominates only very close to the Equator, whereas the stronger emission at other latitudes is at a higher frequency. A detailed study of this effect and of the possible extension of this technique to separate hot and cold plasma components will be reported separately.

The main conclusions, therefore, are that the unique properties of the radio window from which TMR appears to emanate can be used for remote sensing of the plasmapause. When the technique is applied to certain GEOS 1 data, the results indicate that the stronger non-equatorial electrostatic emissions are at frequencies higher than the cold UHR frequency. Emissions at the latter frequency dominate only within ~±1° of the geomagnetic Equator, and their identification may allow the separation of hot and cold plasma populations. As similar emissions to TMR and to NTC have been observed by the Voyager spacecraft at Jupiter and Saturn, these results could have considerable significance for the understanding of the environments of other planets, and could provide a diagnostic tool to study regions of other planetary magnetospheres not accessible to in situ observations by spacecraft.

# Atmospheric angular momentum and the length of day: a common fluctuation with a period near 50 days

Richard B. Langley, Robert W. King & Irwin I. Shapiro

Department of Earth and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

#### Richard D. Rosen & David A. Salstein

Environmental Research and Technology Inc., Concord, Massachusetts 01742, USA

Semiannual, annual and some longer period changes in the rotation of the Earth have long been attributed to meteorological causes<sup>1-3</sup>. More recently some higher frequency variations in the length of day (l.o.d.) were shown to be strongly correlated with variations of the polar component of the angular momentum of the atmosphere<sup>4,5</sup>. However, fluctuations in l.o.d. with periods near 50 days were not definitely identified, because either the sampling was too coarse4 or it extended over too short an interval<sup>5</sup>. Fluctuations in tropical wind speeds with periods in this range have, nevertheless, been studied<sup>4,6,7</sup>, but their counterparts, although expected4, had not been identified in the Earth's rotation. Last year, four astronomical measures of changes in l.o.d. obtained in 1979 were shown to exhibit nearly the same ~50-day fluctuation8. To find out whether this fluctuation was persistent and of meteorological origin we analysed lunar laser ranging (LLR) observations from the McDonald Observatory in Texas and zonal (east-west) wind data deduced from sources distributed over the globe. The relevant data were available for the common period 1976-79. We describe these analyses in turn and then compare the results.

Values of l.o.d. were obtained by smoothing and then differentiating our LLR estimates of the rotation of the Earth as a function of time. These values were corrected for the effects of polar motion with pole positions determined by the Bureau International de l'Heure<sup>10</sup>. Our results were tabulated at 5-day intervals from 2 January 1976 to 27 December 1979. Typically each tabulated value of l.o.d. has an estimated standard error of ~0.1 ms. The uncertainties, however, vary over the 4-yr interval, due in part to the uneven distribution in time of the LLR observations.

To investigate the short-term variations in l.o.d., we used an ad hoc procedure that seems adequate for the purpose. First we divided the l.o.d. time series into nearly year-long segments. For each segment we determined the mean level and, using least squares analysis, the best-fitting Fourier components with annual and semiannual periods. We then removed these components, as well as the fortnightly and monthly tidal terms, from the l.o.d. values. The residual variations are shown for each year in Fig. 1a-d. Each curve is dominated by fluctuations with periods in the range 40-60 days. The typical amplitude of these fluctuations is  $\sim 0.2$  ms, or about half the mean amplitudes of the annual and semiannual terms; the lack of continuity between the curves is due to the procedure used to remove the low-frequency components of the l.o.d. variations.

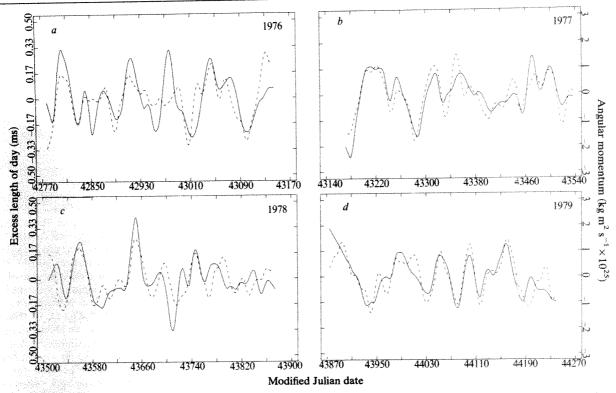

Fig. 1 Variation in length of day determined from lunar laser ranging observations (solid line) and from the angular momentum of the atmosphere (dashed line) for the years 1976-79. The annual and semiannual variations and mean levels of both sets of l.o.d. values, as well as the fortnightly and monthly tidal terms in the lunar laser ranging values, have been removed (see text).

Although appropriate data on the angular momentum of the atmosphere are not available for the time before 1976, useful lunar laser ranging observations extend back to 1971. These, too, exhibit significant fluctuations with periods in the range 40-60 days. Power spectra of the entire set of l.o.d. values, and subsets of them, will be presented and discussed elsewhere.

Our time series of values of the angular momentum of the atmosphere was derived from analyses of the global distribution of zonal winds made twice daily (for 00.00 and 12.00 UTC) by the US National Meteorological Center (NMC)<sup>11</sup>. These analyses are based on data gathered from various sources, including rawinsonde balloons, satellites and commercial aircraft, and provide wind velocities over a grid with points spaced every  $2.5^{\circ}$  in both latitude and longitude, at each of 12 pressure levels ranging from 1,000 to 50 mbar. (A detailed analysis of the spatial and temporal variability of these zonal winds will be presented elsewhere 12.) The values of wind velocity at the grid points were zonally averaged and then, with appropriate weighting, integrated over latitude ( $\phi$ ) and pressure (p) to determine, relative to an Earth-fixed frame, the approximate angular momentum of the atmosphere about the polar axis:

$$h_3(t) = \frac{2\pi a^3}{g} \int_{100 \text{ mbar}}^{1,000 \text{ mbar}} \int_{-\pi/2}^{\pi/2} [u] \cos^2 \phi \, d\phi \, dp$$
 (1)

where [u] is the zonal average of the eastward component of wind velocity, a is the mean radius of the Earth and g is the acceleration due to gravity. Equation (1) is based on the assumption that the atmosphere is in hydrostatic equilibrium and ignores the variation with altitude and latitude of the distance of a parcel of air from the centre of the Earth. Because of the expected unreliability of the data at pressures below 100 mbar (ref. 13), we have ignored these data. Test calculations, using the low pressure data, indicate that deleting them incurs a systematic error of  $\sim 10\%$  in the determination of the mean value of  $h_3$ , but we expect this deletion to have an even smaller impact on day-to-day changes in  $h_3$ . Of greater effect on these changes are the errors that result from gaps in the spatial

distribution of observations, inaccuracies in the basic wind measurements and approximations in the NMC's analysis. We cannot place a reliable quantitative limit on these errors; however, model calculations related to the first two error sources  $^{14}$  and comparisons related to the third indicate that these errors in toto are typically  $\sim 10^{20}$ % or less.

We determined  $h_3$  from equation (1) for twice-daily epochs daily extending from 1 January 1976 to 31 December 1979. The results from December 1978 to November 1979 are thought to be the most accurate because of the intense effort devoted to data collection under the Global Weather Experiment<sup>15</sup>.

Fluctuations in  $h_3$  on time scales of the order of 1 yr or less probably affect only the crust and mantle (hereafter 'shell') of the Earth because the core is thought to participate only in longer period variations<sup>5,16</sup>. For variations with periods <1 yr, then, the relation between the changes  $\Delta h_3$  in  $h_3$  and the corresponding changes  $\Delta \omega$  in the angular velocity of the shell of the Earth is given by

$$\Delta\omega \cong -\frac{\Delta h_3}{I_s} \tag{2}$$

where  $I_s$  is the principal (axial) moment of inertia of the shell. A change in the angular velocity of the shell is related to a change in the observed l.o.d. by

$$\frac{\Delta l.o.d.}{l.o.d.} = -\frac{\Delta \omega}{\omega} \tag{3}$$

Combining equations (2) and (3) and using the following constants:  $I_s \approx 7.04 \times 10^{37} \text{ kg m}^2$  (this value of  $I_s$  was derived from the B1 density model in ref. 17; the uncertainty in  $I_s$  is probably not greater than 2%),  $\omega \approx 7.29 \times 10^{-5} \, s^{-1}$ , l.o.d. = 86,400 s, yields

$$\Delta l.o.d.(s) = 1.68 \times 10^{-29} \, \Delta h_3 \, (kg \, m^2 \, s^{-1})$$
 (4)

The mean level of  $h_3$  between 1 January 1976 and 31 December 1979 is  $\sim 1.4 \times 10^{26}$  kg m<sup>2</sup> s<sup>-1</sup>. This amount of angular momentum transferred to the solid Earth (excluding its core) would change the l.o.d. by 2.3 ms.

As with the values derived from LLR observations, we removed from the l.o.d. values obtained from equations (1) to (4) the mean level and the best-fitting Fourier components with annual and semiannual periods for each yr-long segment separately. The residuals were smoothed using a gaussianshaped low-pass filter, with a window width in the time domain of about 8 days (full-width-at-half-maximum). This degree of smoothing is consistent with the smoothing applied to the LLR estimates of Earth rotation. Figure 1a-d shows the smoothed curves for each year superimposed on the l.o.d. curves obtained from the lunar laser ranging observations. In common with the LLR curves, those derived from the estimates of  $h_3$  are discontinuous from year to year. The scale on the right-hand side is related to the scale on the left through equation (4).

The degree of correlation between the observed (LLR) and the inferred (meteorological) values of the changes in l.o.d. is quite striking; in most places there is good agreement in both the amplitude and phase of the variations. The correlation seems highest in 1979, perhaps due at least in part to the special attention devoted in that year to the collection of meteorological data. Overall, the comparison in Fig. 1 implies strongly that these ~50-day period fluctuations in l.o.d. are 'real' and are related to meteorological effects. The uncertainties in the LLR l.o.d. values and in the estimates of  $h_3$  are large enough to account for the differences in the two sets of curves and therefore too large to make a detailed analysis of these differences worthwhile. These uncertainties are also too large to permit us to place useful limits on the magnitudes of any non-atmospheric contributions to the changes in l.o.d. Thus, we cannot determine from the comparison whether the core participates in these l.o.d. changes nor can we place useful constraints on the contributions of ocean currents and other neglected torques. Other studies 16 imply that the contributions of ocean currents are small. Our calculations indicate that the contributions of other neglected torques are also small.

The exchange of momentum between the Earth's atmosphere and surface has a central role in determining both the structure of atmospheric flow and the dynamics of the Earth's rotation. Observed changes in l.o.d. can provide a constraint for models of atmospheric flow and a (partial) check for global analyses of such motions. The removal of more accurate estimates of the atmospheric contribution to changes in l.o.d. observations might reveal residual variations associated with ocean currents, earthquake fault displacements and core-mantle interactions.

This research was sponsored in part by the Air Force Geophysics Laboratory under contract F19628-79-C-0064 and in part by NASA under grant NSG-7428 and under contracts NAS5-25833 and NAS5-25870. R.B. was supported in part by a National Sciences and Engineering Research Council of Canada Postdoctoral Fellowship. We thank the staffs of McDonald Observatory and the Department of Astronomy of the University of Texas for providing the LLR data and A. J. Miller of NMC for providing the atmospheric data.

# Solvated electrons in the upper atmosphere

#### F. Arnold

Max-Planck-Institut für Kernphysik, Heidelberg, PO Box 103 980, FRG

Solvated electrons have been postulated 1-3 to exist in liquids and solids, and recent laboratory measurements4 have revealed that they exist even in the gas phase. In particular, these measurements suggest that eight water molecules are sufficient to bind an electron and give rise to a solvated electron of the kind (H<sub>2</sub>O)<sub>8</sub>. This seems to be consistent with theoretical considerations<sup>5</sup> suggesting that a dipole of molecular size must have a minimum dipole moment of about 2.5 D to support a bound state. According to theoretical calculations<sup>6</sup>, a cold, neutral water cluster (H<sub>2</sub>O)<sub>8</sub> has a dipole moment of 4.61 D, so that larger (H<sub>2</sub>O), clusters may be expected to bind an electron. Building on these ideas I consider here the possibility that solvated electrons may also exist in the Earth's upper atmosphere and that they may affect nucleation and aerosol formation. Furthermore, I suggest that upper-atmosphere solvated electrons may be detected, using rocket-borne ion mass spectrometers, and that they may be used as tracers for probing condensation nuclei.

In the Earth's upper atmosphere solvated electrons may be formed by attachment of free electrons to clusters of molecules having large dipole moments or polarizabilities. Thus, solvated electron formation would be restricted to regions where both free electrons and the corresponding neutral species are present.

In the atmosphere free electrons essentially exist only at heights above  $\sim 60-65$  km (day) and 75-80 km (night), whereas negative ions represent the atmospheric negatively charged constituents below these heights<sup>7</sup>. The main reason for the rather abrupt transition from a negative ion to an electron regime is electron detachment induced by oxygen atoms<sup>8</sup> which become abundant above these heights'.

Collisions of free electrons with these molecular clusters may give rise to solvated electrons.

The pHs should, in most conditions, not be large enough to give rise to solvated electrons. Sufficiently large pHs and  $(H_2O)_n$ clusters probably occur only in conditions of extremely low temperatures (<150 K) around the mesopause<sup>9</sup>. Such conditions are occasionally met at high geographical latitudes during local summer. In fact, large pHs containing up to 20 water molecules were recently detected by Björn and Arnold 10 using a

rocket-borne ion mass spectrometer.

It has been suggested previously<sup>9,11</sup> that pHs may induce the nucleation of atmospheric water vapour in the cold mesopause region and thereby give rise to a mesospheric haze layer and to noctilucent clouds. As pointed out elsewhere, however, ion nucleation, although being thermodynamically possible, may suffer from severe kinetic limitations. pHs may be rapidly destroyed by dissociative electron recombination and therefore not grow to critical sizes.

Here, I propose an alternative recombination mechanism involving solvated electron formation. Instead of neutralizing the excess proton contained in a large pH the electron may be solvated by water molecules attached to the proton. Thus, a charge doublet composed of a solvated electron and a solvated proton may be formed. Taking measured enthalpy differences for successive proton hydration12 it seems that 11 water molecules are sufficient to stabilize a pH against spontaneous neutralization of its excess proton. In fact, this number of H<sub>2</sub>O molecules is already larger than the eight required for electron solvation.

A doublet may grow by attachment of water molecules and ultimately pick up another electron and thereby be converted to a triplet containing a solvated proton and two solvated electrons. The formation of positive triplets is much less likely as the rate of positive ion collisions is much less than that of electron collisions due to the about 100,000 times larger ion mass. As the triplet carries a negative net charge, it should readily recombine with a positive ion, generally a pH giving rise to the formation of a quasineutral quadruplet. Further electron and ion attachment may lead to larger multiplets. These resemble the stratospheric polyions or multi-ion complexes I recently discussed<sup>13</sup> which, however, contain negative ions rather than solvated electrons.

If the charge multiplets were in fact formed at the mesopause, they may have an important bearing on nucleation, as they may stabilize subcritical water cluster against evaporation and allow for the build-up of critical clusters by electron, pH, and H<sub>2</sub>O attachment.

I now attempt to estimate the abundances of doublets and quadruplets at the mesopause for a steady state situation.

Assuming that doublets are formed by electron recombination of large pHs (fractional abundance f) at a rate coefficient a and are lost only by electron attachment (rate coefficient k), the following steady-state continuity equation is obtained

$$f[pH]\alpha_{e}[e] = [D]k[e]$$
 (2)

which relates the concentration of doublets [D] to the pH and total electron concentrations. Taking  $\alpha_e = 10^{-5} \text{ cm}^3 \text{ s}^{-1}$  (ref. 14) and assuming that every collision of an electron and a doublet leads to electron attachment  $(k = 10^{-7} \text{ cm}^3 \text{ s}^{-1})$  we obtain

$$[\mathbf{D}] \approx f \mathbf{1} \mathbf{O}^2[p\mathbf{H}] \tag{3}$$

Analogously we obtain the steady-state continuity equation for triplets

$$[\mathbf{D}]k[\mathbf{e}] = [\mathbf{T}]\alpha_{\mathbf{I}}[\mathbf{n}_{+}] \tag{4}$$

where  $\alpha_{I}$  is an ion-ion recombination coefficient (usually 15,16  $\sim 6 \times 10^{-8} \text{ cm}^3 \text{ s}^{-1}$ ) and  $[n_+]$  is the total positive ion concentration. Assuming  $[n_+] = [pH] = [e]$  we obtain

$$[T] \approx [D] \tag{5}$$

Evidently the above estimates can, if at all, only apply for f smaller than 0.01, because otherwise triplets would become more abundant than electrons. This would give rise to a depletion of electrons by triplet formation which is in conflict with the assumption of  $[e] = [n_+]$ . Hence, if f was >0.01, one should expect that some depletion of electrons actually occurs, the rates for doublet and triplet formation, however, decrease.

Note that a decrease of [e] due to electron solvation would increase the lifetime of smaller pHs, which are destroyed by dissociative electron recombination, and thus would increase the rate of formation of large pHs. Thus, there would be a strong positive feedback in ion nucleation.

Electron solvation may, of course, be induced by  $(H_2O)_n$ clusters also if these are not formed by ion nucleation but by some other process, as for example, homogeneous nucleation of water vapour condensation on pre-existing particles.

Having discussed electron solvation by neutral and positively charged water clusters, I now consider electron solvation by 'meteoric smoke particles'. These molecular clusters may contain compounds with large dipole moments and polarizabilities which enable them to solvate an electron strongly, because the presence of meteor smoke particles is probably not limited in space and time electron solvations by these clusters may be a common process around the mesopause.

Taking surface area densities for meteoric smoke particles predicted by the model of Hunten et al.<sup>17</sup> and assuming that solvated electrons are lost by recombination with positive ions, an upper limit to the abundance ratio for solvated electrons and electrons of about 0.1 is estimated.

Finally, if solvated electrons were indeed as abundant as estimated above, they should be easily detectable in the meso-

pause region using rocket-borne mass spectrometers. In situ mass spectrometric detection of solvated electrons may be a powerful tool of probing molecular clusters such as (H<sub>2</sub>O)<sub>n</sub> and meteoric smoke particles in the mesopause region.

I thank H. Haberland for information on unpublished laboratory measurements of gas phase solvated electrons and W. Linder for stimulating discussions.

# Halocarbons in the stratosphere

#### P. Fabian & R. Borchers

Max-Planck-Institut für Aeronomie (MPAE), Katlenburg-Lindau, FRG

#### S. A. Penkett & N. J. D. Prosser

Environmental and Medical Sciences Division, AERE, Harwell OX11 0RA, UK

The possible impact of chlorine compounds on the Earth's ozone layer has caused concern. Profiles of the anthropogenic halocarbons F-11 (CFCl<sub>3</sub>) and F-12 (CF<sub>2</sub>Cl<sub>2</sub>) have already been measured in the stratosphere1-4. Measurements of the vertical distribution of methyl chloride (CH3Cl), the most important natural chlorine-bearing species confirm that chlorine of anthropogenic origin now predominates the stratosphere<sup>5</sup> More halogen radicals are added through decomposition of various other halocarbons, most of them released by man. We report here the first measurements of vertical profiles of F-13 (CF<sub>3</sub>Cl), F-14 (CF<sub>4</sub>), F-113 (C<sub>2</sub>F<sub>3</sub>Cl<sub>3</sub>), F-114 (C<sub>2</sub>F<sub>4</sub>Cl<sub>2</sub>), F-115 (C<sub>2</sub>F<sub>5</sub>Cl), F-116 (C<sub>2</sub>F<sub>6</sub>), and F-13 B(CF<sub>3</sub>Br) resulting from gas chromatography-mass spectrometer (GC-MS) analysis of air samples collected cryogenically between 10 and 33 km, at 44° N. Some data for F-22 (CHF<sub>2</sub>Cl), methyl bromide (CH<sub>3</sub>Br) and methyl chloroform (CH<sub>3</sub>CCl<sub>3</sub>) also presented are subject to confirmation.

Cryogenic sampling with subsequent analysis of the samples in the laboratory is an excellent tool for simultaneously measuring a variety of stable trace gases in the atmosphere 1,2; vertical profiles of H<sub>2</sub>, CH<sub>4</sub>, CO, CO<sub>2</sub>, N<sub>2</sub>O, CFCl<sub>3</sub>, CF<sub>2</sub>Cl<sub>2</sub> and CH<sub>3</sub>Cl have already been measured up to ~36 km altitude. From a recent balloon flight of the MPAE neon-cooled sampler launched on 25 September 1980, in southern France (44° N), seven stratospheric air samples were recovered. While the first one of these had been taken during the ascent at 10 km height, the six other samples were collected during the descent of the heliumfilled balloon at 33.2, 28.8, 25.9, 23.3, 20.0 and 14.4 km, respectively. These figures correspond to the centres of the sampling height intervals whose ranges varied between 0.2 and 0.5 km. The slow descent, at a rate of ~50-100 m min<sup>-1</sup>, was achieved be releasing gas through a remotely controlled valve on top of the balloon.

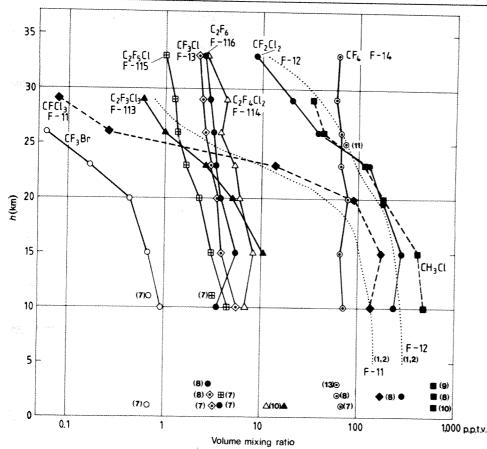

Fig. 1 Vertical profiles of halocarbons measured at 44° N by GC-MS analysis of cryogenically collected balloon samples. Results from measurements made by other authors (reference numbers in parentheses are shown for comparison). The tropospheric data shown at the bottom are not related to the height scale.

Immediately after the flight, the samples were transferred into 1.6-l stainless steel bottles electropolished internally and fitted with metal bellows valves. Each bottle contained a sample of about 8-101 of air at STP that was analysed three weeks later using a GC-MS combination at AERE Harwell (Hewlett Packard 5710 GC/VG Micromass 16 FMS). As repetitive analyses of previously collected samples had shown, F-13, F-14, F-113, F-114, F-115, F-116, and F-13B remain stable in these bottles over a period of more than 6 months (S.A.P. and R. A. Rasmussen, unpublished data). Because many of the concentrations to be measured were below the detection limit for direct analysis of a 5-ml sample, a cryotrap concentrator described elsewhere was used for all analyses. The volumes of air used for each estimation varied between 100 ml and 1 l, which is a substantial fraction of the total sample. Duplicate analyses were generally not performed so that data on a wide range of species could be recorded. The precision of the analysis is  $\pm 15\%$  for every individual data point, while the error of the absolute calibration is  $\pm 10\%$  for all constituents shown here. Typically the detection limit is of the order of 0.1 p.p.t.v. (1 p.p.t.v. = 1 part in 1012 by volume) for a 1-l sample.

The results are plotted in Fig. 1. The upper parts of some of the profiles, where the mixing ratio fell below the detection limit, are not shown. Measurements made by other authors are included for comparison.

The low-altitude sample collected during the ascent at 10 km was obviously diluted by the helium that had been filled into the air intake system of the cryogenic sampler before launch. This is confirmed by the comparison of the data from the 10-km balloon sample with those obtained from samples collected cryogenically aboard a Learjet aircraft over southwestern UK at almost the same time and altitude (S.A.P. and R. A. Rasmussen, unpublished data). For most constituents, the mixing ratios analysed from the balloon sample taken at 10 km are lower than those obtained from the Learjet samples. A correction factor can be applied to this lowest balloon sample based on measurements of common constituents such as F-11 and F-12 in both balloon and aircraft samples. This suggests that the mixing

ratios in the 10-km balloon sample are  $\sim$ 20% low, which needs to be born in mind when referring to the profiles shown in Fig. 1.

Stratospheric profiles of CFCl<sub>3</sub>, CF<sub>2</sub>Cl<sub>2</sub> and CH<sub>3</sub>Cl have already been documented<sup>1-6</sup>. Below ~20 km the mixing ratios of both CFCl<sub>3</sub> and CF<sub>2</sub>Cl<sub>2</sub> are higher than those given by the average profiles measured in June 1979 at the same latitude<sup>1.2</sup>, also shown in Fig. 1 (dotted lines). Between June 1977 and June 1979, an increase of the average tropospheric mixing ratio of CFCl<sub>3</sub> from 130 to 147 p.p.t.v. had been observed at 44° N. During the same time CF<sub>2</sub>Cl<sub>2</sub> increased from 240 to 292 p.p.t.v. (refs 1, 2). The increase between June 1979 and September 1980 shown here is in reasonable agreement with that observed earlier. Above 25 km the mixing ratio of F-11 falls off more rapidly than the average profile for 1979.

The stratospheric profile obtained for CH<sub>3</sub>Cl agrees fairly well with that measured in June 1978 <sup>5</sup> if the uppermost point is omitted. The increase of the CH<sub>3</sub>Cl mixing ratio above 30 km may be due to contamination of the sample collected at ceiling altitude. Three near-surface measurements of 630 p.p.t.v. (ref. 8), 624 p.p.t.v. (ref. 9) and 611 p.p.t.v. (ref. 10) are shown at the bottom of Fig. 1 for comparison. Their display, which was made for the sake of clarity, has no relation to the height scale of Fig. 1. The same holds for the other tropospheric data plotted in Fig. 1. CH<sub>3</sub>Cl is a natural constituent with the ocean being its main source<sup>9</sup>.

The other halocarbons whose vertical distributions are shown in Fig. 1 have, to our knowledge, not yet been measured in the stratosphere, with the exception of F-14 ( $CF_4$ ) for which one data point—75 p.p.t.v. at 25 km—was measured by Goldman et al. 11. In the troposphere some measurements exist for most of these constituents, and these data have been included at the bottom of Fig. 1 to be identified by the same symbols as used in the stratospheric profiles. Two data points for  $CF_3Br$  and  $C_2F_5Cl$ , respectively, as analysed from aircraft samples taken at 11 km (ref. 7) are also shown for comparison.

F-13 B (CF<sub>3</sub>Br), a bromine compound of anthropogenic origin, is used as a fire extinguisher. Its abundance, about 0.7 p.t.t.v. in the troposphere<sup>7</sup>, is mostly due to anthropogenic

release. In the stratosphere CF<sub>3</sub>Br mixing ratios decrease, from about 1 p.p.t.v. at 10 km to 0.06 p.p.t.v. at 25.9 km. It has been argued7 that this decrease may be due to photolysis by which bromine is released augmenting the effect that natural bromine has on removing ozone. Methyl bromide (CH<sub>3</sub>Br) is, like methyl chloride, predominantly of a natural origin. Tropospheric measurements of CH3Br suggest mixing ratios ranging between 5 and 25 p.p.t.v. (ref. 8). If our measurements are correct, then in the stratosphere the mixing ratio of CH<sub>3</sub>Br falls off rapidly: 1.2 p.p.t.v. was measured at 14.4 km, while the sample taken at 20 km was already below the detection limit. These data are not shown in Fig. 1.

The aluminium industry<sup>7</sup> is probably the major source for both F-14 (CF<sub>4</sub>) and F-116 (C<sub>2</sub>F<sub>6</sub>). F-14 is a very stable constituent12 showing almost no vertical gradient in the stratosphere. Its mixing ratio was measured as 65 p.p.t.v. at 14.4 km and 62 p.p.t.v. at 33.2 km; the single data point measured by Goldman et al.11 fits this profile quite well. Tropospheric CF4 mixing ratios, with averages of 69.9 p.p.t.v. (ref. 7), 63.6 p.p.t.v. (ref. 13) and 65 p.p.t.v. (ref. 8) measured in the Northern Hemisphere, match our stratospheric data within the quoted error limits. F-116 decreases from about 4 p.p.t.v. measured at 10 km to 2.5 p.p.t.v. at 33.2. This difference from F-14 may be due to a more rapid buildup in the atmosphere or due to stratospheric decomposition. The tropospheric mixing ratio of 4 p.p.t.v. measured in 1979 is in good agreement with our data.

The results for F-13 (CF<sub>3</sub>Cl) and F-115 (C<sub>2</sub>F<sub>5</sub>Cl) are interesting. It was suggested earlier that F-115 is growing more rapidly than other anthropogenic species containing the CF<sub>3</sub> grouping, possibly because it is used in conjunction with F-22 (CHF<sub>2</sub>Cl) in the refrigerant F-502. This may account for the steeper profile for F-115 whose mixing ratios decrease from 3.1 p.p.t.v. at 14.4 km to 1.0 p.p.t.v. at 33.2 km, compared with that for F-13 which falls from 3.9 p.p.t.v. at 14.4 km to 2.3 p.p.t.v. at 33.2 km. A comparison with tropospheric F-13 mixing ratios, of 3.4 p.p.t.v. (ref. 7) and 3.0 p.p.t.v. (ref. 8) measured in 1979, seems to suggest that F-13 is also increasing with time. For F-115 a tropospheric mixing ratio of 4.1 p.p.t.v. was measured in 1980 (ref. 7).

Our stratospheric profile for F-22 shows a decrease from  $\sim 50$ p.p.t.v. at 10 km to ~10 p.p.t.v. at 33.2 km. This is an important species to measure both because of its rapid growth rate14 and because it contains a hydrogen atom and therefore will react with hydroxyl radicals in the stratosphere. Our data must be considered preliminary though, because of inconsistencies apparent on reanalysis after a 3 months gap. The profile is therefore not shown on Fig. 1.

F-113 (C<sub>2</sub>F<sub>3</sub>Cl<sub>3</sub>) and F-114 (C<sub>2</sub>F<sub>4</sub>Cl<sub>2</sub>) are used as refrigerants. Their tropospheric abundances, which have been measured extensively by Singh et al.10, are 19 and 12 p.p.t.v., respectively, on the Northern Hemisphere. In the stratosphere F-113 is rapidly decomposed, its mixing ratio decreases to 0.6 p.p.t.v. at 28.8 km. The stratospheric decomposition of F-114 is much slower; its mixing ratios decrease from about 8.5 p.p.t.v. at 14.4 km to 2.7 p.p.t.v. at 33.2 km.

Methyl chloroform (CH<sub>3</sub>CCl<sub>3</sub>), mainly used as a dry cleaning solvent, has been suggested 10 as a potential depleter of stratospheric ozone due to its rapid growth in the lower atmosphere (15.5 p.p.t.v. yr<sup>-1</sup>). For the Northern Hemisphere Singh et al.<sup>10</sup> published an average mixing ratio of 113 p.p.t.v., based on measurements made at the end of 1977, while Rasmussen and Khalil<sup>8</sup> measured an average of 135 p.p.t.v. during mid-1979. Our vertical profile measured in the stratosphere indicates that CH<sub>3</sub>CCl<sub>3</sub> is rapidly decomposed. The mixing ratios decrease from  $\sim 100$  p.p.t.v. at 10 km to 1 p.p.t.v. at 23.3 km. These measurements were made 3 weeks after the samples had been taken. Analyses taken 3 months later showed that methyl chloroform had completely disappeared from the containers (carbon tetrachloride had already disappeared 3 weeks after sampling, when the first analyses were made; thus no CCl<sub>4</sub> profile can be presented). Because the above values for CH<sub>3</sub>CCl<sub>3</sub> are preliminary they are not displayed in Fig. 1. As the

present annual growth rate of CH<sub>3</sub>CCl<sub>3</sub> is much faster than that of CFCl<sub>3</sub> (ref. 10) it might add comparable amounts of ClO<sub>x</sub> radicals to the stratosphere within a forseeable time.

Our results demonstrate that besides F-11, F-12 and CH<sub>3</sub>Cl there are quite a few halocarbons, mostly anthropogenic, that contribute to the stratospheric halogen budget. Above 30 km the amount of organically bound chlorine present as F-113, F-115, F-13, F-114, and F-22 combined is comparable with that present as F-11 and F-12.

The work at AERE Harwell was funded as part of an air pollution research programme sponsored by the UK Department of Environment. We also thank this Department for its substantial contribution towards the cost of the balloon launch.

### Anomalous wind estimates from the Seasat scatterometer

T. H. Guymer\*, J. A. Businger†, W. L. Jones‡ & R. H. Stewart§

The Seasat-A Satellite Scatterometer(SASS) measured the radar backscatter intensity from the sea surface using a fourbeam microwave antenna<sup>1-3</sup>. Estimates of wind speed and direction derived from these data agree well with surface measurements made during the Joint Air-Sea Interaction (JASIN) experiment<sup>4-6</sup>, but there are occasions (3 out of 23 satellite passes) when the results are anomalous. We have now studied one such occasion when the satellite measurements differed substantially from those at the surface of the sea and conclude that the interpretation of the SASS measurements may have been vitiated by a mid-level convective system deep enough to produce thunderstorms and lightning.

Figure 1 shows a plot of the SASS wind vectors for Rev. 557 (23.16 GMT, 4 August 1978) together with wind speeds measured by ships at the corners of the JASIN meteorological triangle. Over most of the area SASS winds are 7 m s<sup>-1</sup> or less but in a region centred on 59.1 °N and 12.0 °W, the SASS speeds are about 17 m s<sup>-1</sup>, which, given the rather weak pressure gradient, seems unlikely. Moreover, examination of a similar SASS plot for Rev. 556, 100 min earlier, revealed no apparent irregularities at the same location.

To understand this discrepancy we examined the individual normalized radar backscatter coefficients,  $\sigma^{\circ}$ —the basic scatterometer data from which wind vectors are derived. The region of anomalously high winds exhibited localized, large  $\sigma^{\circ}$  obtained

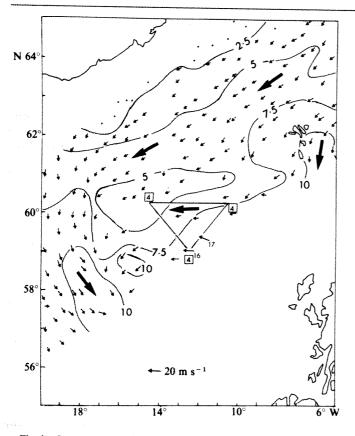

Fig. 1 Scatterometer wind vectors for Rev. 557, 23.16 GMT on 4 August 1978 (wind speeds in m s<sup>-1</sup>). The harmonic nature of the algorithm used to convert backscatter intensity to wind velocity means that up to four solutions are obtained for each footprint<sup>10</sup>, each having similar speeds but differing widely in direction. A preferred direction has been manually selected in each case to ensure dynamic consistency and to give closest agreement with routinely produced surface pressure fields. Anomalous speeds near the southern corner of the JASIN meteorological triangle have been annotated and points without arrows indicate wind speeds of 3 m s<sup>-1</sup> or less. Numbers in boxes denote speeds measured by ships at the corners of the triangle.

from the backward and forward looking antennas (beams 3 and 4 respectively) on the left-hand side of the satellite for both vertical and horizontal polarizations. Figure 2 shows contour plots of  $\sigma^{\circ}$ , adjusted to remove incidence angle dependence, for beam 3 vertical polarization. High-backscatter regions along a 300-400 km line lying to the south-east of the JASIN meteorological triangle and aligned NE/SW were not present on the previous pass although near 59 °N 10.5 °W there was a suggestion of increased  $\sigma^{\circ}$ . This corresponded closely with a region of increased liquid water as inferred from the Scanning Multichannel Microwave Radiometer (SMMR) (Fig. 3) and also with a small feature in the synthetic aperture radar image apparently oriented ESE/WNW. Unfortunately, the sampling characteristics of these two instruments meant no information in the area of interest could be obtained on Rev. 557. As these results suggested that the scatterometer anomalies were associated with a meteorological event of rather small scale, the meteorological data available for the JASIN area were studied.

The UK Meteorological Office analysis at 18.00 GMT showed fronts approaching the area from both the west (front A) and from the north-east (front B). Time series of surface winds from several platforms showed that at the passage of B the wind veered by 50° and increased by 3-4 m s<sup>-1</sup>. The times at which this change occurred at each of the platforms suggested southwestward propagation of the front at 5 m s<sup>-1</sup>. A NOAA-5 IR satellite image at 18.16 GMT revealed that B was not accompanied by a well-defined band of cloud. However, at 58.5 °N, 9.5 °W there was evidence of deep convective cloud. Subsequent cloud pictures at 20.09 and 21.33 GMT from the Seasat visible

and IR radiometer (VIRR) indicated that the feature moved westwards at  $\sim$ 7 m s<sup>-1</sup> to occupy the area 58-59 °N and 10-12 °W at 21.33 GMT which is close to the position of the liquid water maximum observed by the microwave radiometer at the same time. The shape of the cloud mass resembles that of the region of high backscatter at 23.16 GMT.

Some idea of the structure of the upper air in between fronts A and B can be gained from the JASIN radiosonde ascents. On 4 August ascents were made at approximately hourly intervals throughout daylight hours from ships at the corners of the 200-km triangle. Preliminary analysis indicates similar structure at all three corners. The most significant feature is the deep, moist layer in middle levels of the troposphere. At the base of this layer there is a marked temperature inversion such that convection from the surface cannot penetrate above a height of ~2 km. However, the air above would be quite unstable if lifted by a small amount and could support deep convection extending from 2 to 6 km. The inversion marks the frontal surface of a cold occlusion and it is when the surface front passes that the wind veer occurs. Convergence at this feature could release the potential instability aloft.

Upper-air winds were deduced from Loran-C tracking of the sondes and, assuming the convective system to be steered with the mid-tropospheric flow<sup>7</sup>, implied a propagation velocity of 6-7 m s<sup>-1</sup> towards 280°, that is with a significant component parallel to the front. This is consistent with the sequence of cloud photographs and suggests that the feature would be carried over the southern part of the triangle at about 23.00 GMT. The weather logs of the JASIN ships revealed that thunderstorm activity had been reported by three ships in that region between 21.00 GMT and midnight (see Fig. 4 for a synoptic chart).

We conclude that the anomalous SASS winds occurred in a region where deep mid-level convection was taking place. Possible explanations for the unrealistic satellite winds are: (1) that the regions of high backscatter (Fig. 2) are associated with increasing ocean surface roughness due to locally high winds in the vicinity of the convective cells which are small compared with the SASS resolution cell  $(18 \times 70 \text{ km})$ ; (2) the large raindrops in the storm may significantly modify the ocean surface

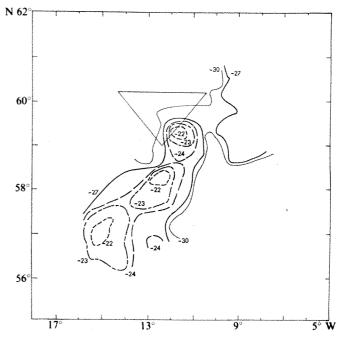

Fig. 2 Contours of normalized backscatter intensity  $(\sigma^\circ)$  obtained from part of the left-hand backward viewing SASS beam in the vertical polarization mode. Rev 557, 23.16 GMT 4 August 1978. Units are Db. Values of  $\sigma^\circ$  have been corrected for variation with incidence angle. To deduce wind direction data from two beams are combined with a consequent loss of areal coverage, hence the difference between Figs 1 and 2.

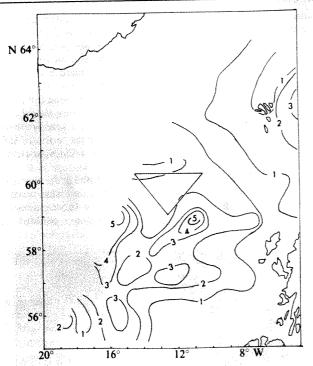

Fig. 3 Contours of vertically-integrated liquid water (units in 0.1 kg m<sup>-2</sup>) for Rev 556, 21.33 GMT 4 August as deduced from SMMR.

roughness, thereby invalidating the relationship between  $\sigma^{\circ}$  and wind vector; and (3) the rain may be responsible for additional backscatter in the atmosphere.

Concerning explanation (1), although thunderstorms<sup>8,9</sup> can produce large gusts at the surface through the evaporation of precipitation into the downdraught, on this occasion there was no evidence from surface data sampled at 1-min intervals that gusts exceeded 8 m s<sup>-1</sup> which is consistent with the observed thermodynamic structure.

For explanation (2), recent radar scattering experiments (Moore, personal communication) conducted in a wind/wave

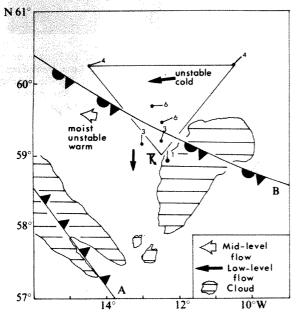

Fig. 4 Synoptic chart showing surface winds in the JASIN area (speeds in m s $^{-1}$ ) and the positions of fronts A and B at 22.00 GMT. Areas of deeper cloud, as identified from Seasat VIRR imagery, are also indicated together with information on the characteristics of the flow at mid-levels obtained from radiosonde data in the JASIN area.

tank have shown that the backscatter from small-scale surface roughness produced by artificial rain predominates for light wind conditions (<10 m s<sup>-1</sup>). To account for the large  $\sigma^{\circ}$ , the affected area would have to be several tens of km2 with moderate rain rates (5-10 mm h<sup>-1</sup>).

Finally, for explanation (3), calculations show that the large  $\sigma^{\circ}$ could be the result of backscatter from a single, localized rain cell. Assuming a thunderstorm cell size of 80 km<sup>2</sup> and a vertical rain column of 5 km would require rain rates of ~12 mm h account for the observed  $\sigma^{\circ}$ . Surface observations from ships near the anomaly indicate mainly light rain (0-2 mm h<sup>-1</sup>) but with heavy rain showers at one ship from 23.32-23.45 GMT. It seems that the anomaly was caused by either direct or indirect effects of rain or a combination of the two. Other factors which might lead to high backscatter are hail, which, because of its extremely limited extent is unlikely to have been observed from the ship array, and h.f. interference due to lightning

Further work is necessary to clarify why SASS fails to give realistic winds. This is of special interest if a combination of different Seasat sensors and ground-based observations indicate that the anomaly is related to an actual atmospheric phenomenon (as above) which otherwise might not be detected. Detailed analysis of the combined JASIN/Seasat data set should improve our understanding of air-sea interaction and the links between the near-surface layers and larger scales.

The Seasat Scanning Multichannel Microwave Radiometer  $(SMMR)^{1,2}$  determined the total atmospheric water vapour,  $q_0$ over 600-km wide swaths with a resolution of 54 km. Using radiosonde data from the Joint Air-Sea Interaction experiment, JASIN<sup>3</sup>, we show here that the SMMR  $q_t$  distributions can be used to detect the position of atmospheric fronts in the lower troposphere. Unlike visible and IR radiometry these SMMR determinations are not hampered by extensive cirrus or by lack of frontal cloud. Advantages of the SMMR over previous passive microwave instruments on satellites such as Nimbus 5 and 6 (refs 4-9) are: the use of more channels, allowing better discrimination between the effects of liquid water, water vapour and sea state; and improved spatial resolution. The SMMR performance has been evaluated at several workshops 10-14. Our results 15 show that the SMMR  $q_i$  determinations have similar accuracy to in situ radiosonde measurements.

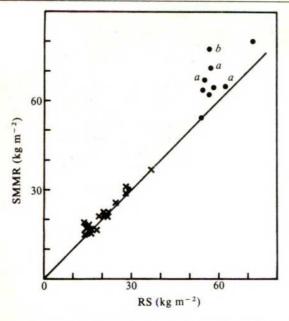

Fig. 1 Comparison of integrated atmospheric water vapour  $q_t$  as measured by the SMMR and by radiosondes.  $\times$ , JASIN values;  $\odot$ , tropical soundings. a indicates tropical soundings for which SMMR values may be too high due to the island of Guam being within the field of view. b, SMMR values may have been affected by heavy rain.

Independently evaluated SMMR and radiosonde estimates of  $q_t$  were compared at the Seasat-JASIN Workshop<sup>13</sup> (Fig. 1). The SMMR results were evaluated using the Wentz algorithm<sup>10</sup>, the nearest grid values being linearly interpolated to the radiosonde launch position. Radiosonde data from the JASIN experiment, conducted in the North Atlantic (60 °N, 12 °W) during July to September 1978³, are shown. Specially calibrated fast sampling radiosondes were used and comparisons restricted to flights launched within  $\pm 2$  h of Seasat overpass time. Estimated accuracy of the radiosonde  $q_t$  value was  $-\pm 1.7$  kg m<sup>-2</sup> (ref. 13). The mean difference, SMMR minus radiosonde, was  $1.2\pm 1.6$  kg m<sup>-2</sup>. To provide comparison at higher  $q_t$  values

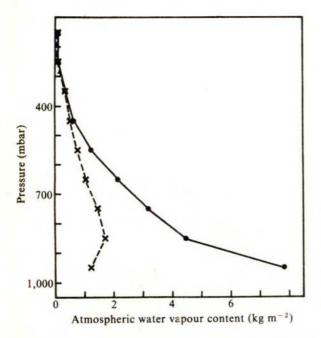

Fig. 2 Mean atmospheric water vapour content of 100-mbar layers during JASIN. Solid line shows the mean value and the dashed line the standard deviation of individual observations for some 200 radiosonde flights of which 110 reached 400 mbar.

radiosonde flights from tropical islands and weather ship Tango are also plotted. These are standard synoptic ascents within 3 h of overpass time. Estimates of  $q_t$  cannot be obtained over land and the tropical island of Guam, being significant in size compared with the SMMR resolution, may have affected the data for three flights marked. One comparison may be affected by local heavy rain. Eliminating these flights the mean difference is  $4.9 \pm 3.7$  kg m $^{-2}$ . Radiosonde errors would be expected to be greater in these ascents and, as for JASIN, the actual error due to the SMMR is not known. However, changes to the SMMR evaluation procedures following the Seasat–JASIN workshop have shown reduced biases<sup>14</sup>.

The SMMR also provided liquid water and rain rate estimates; however, no quantitative evaluation was possible because of the difficulty of obtaining reliable *in situ* measurements. The horizontal variation of liquid water content was

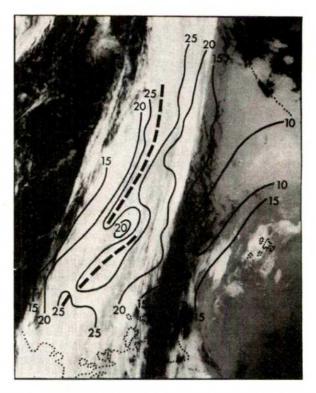

Fig. 3 NOAA 5 IR satellite photograph at  $10.37\,\mathrm{GMT}$  on 5 September 1978 showing a front stretching from Ireland and Scotland (lower left) to Iceland (upper right). SMMR derived values of  $q_{\rm t}$  are shown in kg m<sup>-2</sup>. The dashed line marks the maximum in these values. (Photograph: University of Dundee.)

qualitatively consistent with the meteorological conditions (see ref. 16). For JASIN, SMMR indicated rain when precipitation was 'widespread'—reported by several JASIN ships. Light scattered showers were not detected probably because such showers have horizontal dimensions very much less than the SMMR resolution. Although difficult to obtain  $^{17}$ , quantitative determination of rainfall would have obvious meteorological value. Rain detection is also needed to flag doubtful  $q_t$  values (Fig. 1). However, two different rain rate algorithms used in SMMR evaluation gave different quantitative results showing that much more work is needed on this variable.

The accurate horizontal distributions of  $q_t$  provided by SMMR are useful not only for the calculation of atmospheric water budgets<sup>18</sup>, but also for determining the position of synoptic scale fronts in the lower troposphere. To demonstrate this we need to consider the vertical distribution of water vapour in the atmosphere. Figure 2 shows the mean water vapour content of each 100-mbar atmospheric layer for the whole of the JASIN experiment. The water vapour content falls rapidly with

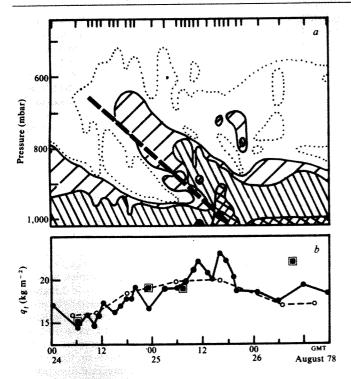

Fig. 4 a, Time-height atmospheric cross-section showing the variation of specific humidity with the passage of a warm front. Values shown are 2 g per kg (dotted), 4-6 g per kg (wide diagonals), 6-8 g per kg (close diagonals), above 8 g per kg (crosshatched). The section is based on 31 radiosonde flights at the times marked at the top. The dashed line marks the approximate region of the frontal surface. b, Values of  $q_t$  from the radiosonde data (solid line), SMMR (■) and SMMR q<sub>t</sub> distribution at 07.30 GMT on 24 August. The moist air ascending the front results in an increase in  $q_t$  with time to a maximum at about the time of surface frontal passage. Following the front there is a decrease to the warm air boundary layer value.

decreasing pressure and temperature, ~80% of the total occurring in the lowest 250 mbar. In contrast the variability of water vapour content is a maximum not at the surface but in the 900-800 mbar layer, and decreases less rapidly, 80% of the variation being spread over the lowest 400 mbar. Thus for this mid-latitude area, although the surface boundary layer is typically 1-2 km deep and contains much of the water vapour, the variability of  $q_t$  is not dominated by boundary layer processes but reflects changes in humidity at levels up to 5 km. Synoptic scale fronts cause moistening at these levels and hence result in significant variations of  $q_t$ . For example, Fig. 3 shows a NOAA 5 satellite IR image in which an occluded front is marked by a 250-km wide band of cirrus which masks any lower level clouds. The variation of  $q_t$  measured by SMMR showed a strong maximum associated with the front, marked in Fig. 3 by the broken line. The position of this maximum was well defined to within the 54-km SMMR resolution, except in one area where a more complicated frontal structure was indicated.

The actual position of the surface front relative to the  $q_t$ maximum will vary from case to case. As an example Fig. 4a shows a radiosonde derived time-height cross-section of specific humidity during the passage of a warm front. Although the front was a significant feature of the radiosonde data, lack of frontal cloud prevented its detection in visible or IR satellite images. The corresponding variation of  $q_t$  is shown in Fig. 4b. SMMR values are in reasonable agreement with the radiosonde values. A difference on the 26 August was probably caused by larger values of  $q_t$  occurring just outside the JASIN area but within the SMMR resolution cell. Radiosonde observations from other JASIN ships show that the front propagated through the area with little change in structure and hence the SMMR horizontal q distribution for 07.30 GMT on 24 August has been transformed

to the time variation shown by the dashed line in Fig. 4. Both radiosondes and SMMR show that, in spite of a marked reduction in boundary layer height, there was a gradual increase of  $q_i$ with the approach of the front. The surface passage of the front was marked by a sharp decrease of  $q_i$  to the warm air boundary layer value. By mapping these  $q_t$  variations in the SMMR data from several Seasat orbits the changing position and alignment of the front have been determined more precisely than was possible using the conventional meteorological observations.

Detection of synoptic fronts in the lower troposphere using SMMR  $q_1$  measurements offers an important new aid for meteorological analysis which is already proving valuable in the interpretation of the JASIN data.

# **Anomalous magnetic directions** recorded by laboratory-induced chemical remanent magnetization

#### Monika E. Bailey & Christopher J. Hale

Geophysics Division, Department of Physics and Department of Geology, University of Toronto, Toronto, Canada M5S 1A7

It has been generally accepted that chemical remanent magnetization (CRM) is acquired either in the direction of the ambient field at the time of chemical alteration or in the direction of a pre-existing natural remanent magnetization (NRM)<sup>2-4</sup>. We report here our experiments in which CRM is carried by magnetite formed during laboratory heating of titanomaghaemite in submarine basalts. This CRM is a stable, single component remanence, acquired in an intermediate direction between the ambient field and pre-existing NRM direction. The role of prior NRM in controlling the direction of CRM is suppressed by externally applied fields of  $\approx 50 \mu T$ . (0.5 Oe) but is prominent in fields of  $\approx 20 \,\mu\text{T}$ . Thus, stable, intermediate-direction CRMs acquired in past geomagnetic fields are a possibility.

CRM was induced in samples from Site 332B of Leg 37 of the Deep Sea Drilling Project. The chemical alteration that occurs when these basalts are heated above 200 °C has been well documented<sup>4-7</sup>. principal mineral. The magnetic titanomaghaemite, breaks down forming an intergrowth of a strongly magnetic titanium-poor titanomagnetite, near magnetite in composition and a titanium-rich phase with a composition close to ilmenite. The NRMs of our samples were moderately strong ( $> 0.1 \text{ A m}^{-1}$ ). The Curie temperatures lay between 330 and 365 °C before the laboratory heating. After the samples were heated their Curie temperatures were close to

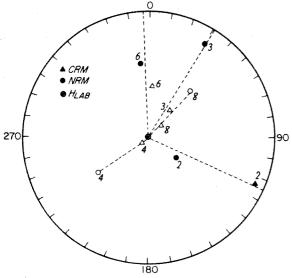

Fig. 1 Equal area plot showing the direction of CRM relative to the laboratory field and the initial NRM direction. Solid (open) symbols denote positive (negative) inclinations. CRM was induced in a 20  $\mu T$  (0.2 Oe) laboratory field in samples 2 and 4 and in a 10  $\mu T$  (0.1 Oe) field in samples 3, 6 and 8. The CRM direction is displaced away from the laboratory field direction towards the NRM direction.

 $580\,^{\circ}\mathrm{C}$ , indistinguishable from the value for pure magnetite. Hysteresis parameters measured before heating indicate that the titanomaghaemite is present as large ( $\approx 20~\mu\mathrm{m}$ ) pseudosingle-domain grains. (The ratio of saturation remanence to saturation magnetization,  $J_{\rm rs}/J_{\rm s}$ , ranges from 0.08 to 0.15.) The magnetite-like phase, which is produced during heating, is present as very fine single-domain grains, having  $J_{\rm rs}/J_{\rm s}$  ratios between 0.33 and 0.36.

CRMs were induced in eight samples. Each 1 cm (o.d) by

1.5 cm long cylindrical sample was divided into two sub-samples before CRM was induced. The initial NRM was left intact in the first specimen while the second was demagnetized by tumbling in a peak alternating field of 100 mT. The use of two sub-samples allowed us to study separately the roles of the external field and the NRM in determining the direction of CRM. CRM was produced by simultaneously heating both specimens slowly ( $\approx 100~^{\circ}\text{C h}^{-1})$  in vacuo (10 $^{-2}$  torr) to a temperature of 515  $^{\circ}\text{C}$  which was then held for 24 h. Fresh samples were used during successive heatings in laboratory fields of 0, 10, 20 and 50  $\mu\text{T}$ . The fields were applied along the cylindrical axis of each specimen without regard to the NRM direction of the sample. After heating, the samples were cooled in a null field ( $<10^{-2}~\mu\text{T}$ ) to avoid the acquisition of thermoremanent magnetization or TRM.

CRMs acquired in 50 µT all lay along the direction of the laboratory field. The presence of an initial NRM had no apparent effect on the direction of CRM. Strikingly different results were obtained with smaller inducing fields (Fig. 1). In five of the eight samples studied, the CRM in samples with an initially intact NRM did not lie in the laboratory field direction. The CRM directions in these samples were deflected by as much as 110° from the laboratory field direction towards the initial NRM direction. The CRM in samples which were initially demagnetized always lay in the external field direction. All the CRM directions were stable in alternating fields up to 100 mT (Fig. 2). The CRM produced with an intermediate direction is therefore a single, directionally stable component and is not a vector sum of components in the laboratory field and NRM directions. Slight initial directional changes on demagnetization are attributed to the removal of viscous components acquired by fine grained magnetite near superparamagnetic size. The CRMs were magneticaly hard with median demagnetizing fields (MDFs) of 57-68 mT (Fig. 3). This contrasts with the magnetically soft NRM of the parent titanomagnaemite in which MDFs ranged from 11 to 15 mT.

Alternating field demagnetization curves of CRM were compared with those of saturation isothermal remanence

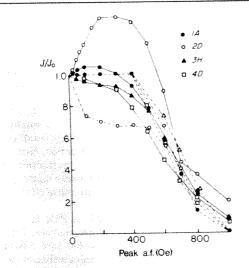

Fig. 3 Intensity of CRM and ARM during a.f. demagnetization. CRM is given by a solid line, ARM by a dashed line.

(SIRM)-and also of anhysteretic remanent magnetization (ARM) acquired in biasing fields of 50 µT and 100 mT a.f. Both the ARM and the SIRM were partially thermally demagnetized by a rapid heating to 515 °C in a null field before a.f. demagnetization was begun. This allowed us to compare the coercivity spectra in the same blocking temperature range for each type of remanence. The a.f. demagnetization curves of CRM, ARM and SIRM are essentially the same at a.f. levels above 40 mT. It would, therefore, be difficult to identify the CRM on the basis of a comparison of coercivity spectra. Differences in the portion of the coercivity spectra below 40 mT result from VRM acquired between the acquisition of CRM and its subsequent measurement. The ARM was demagnetized immediately after acquisition and the samples had little time in which to acquire VRM.

As further chemical alteration accompanied heating to temperatures above 515 °C, a direct comparison of the properties of TRM and CRM in the 515-580 °C blocking temperature range was not possible.

We conclude that both the ambient magnetic field and preexisting NRM have a role in determining the direction of CRM. In ambient fields of <50 µT the CRM may lie in a direction between the NRM direction and the ambient field direction. Neither of these directions can be recovered by techniques such as vector subtraction of a.f. demagnetization data.

CRM of this type will be difficult if not impossible to distinguish from other remanences on the basis of a.f. demagnetization curves. A direct comparison of CRM with TRM coercivity spectra was not possible because further chemical alteration accompanies heating above 515 °C, but we have found that the a.f. demagnetization characteristics of the CRM are very similar to those of ARM which is often considered an analogue of TRM<sup>8</sup>

It cannot therefore be assumed that CRM will faithfully record the geomagnetic field direction either at the time of the sample formation or when they alter later. A particularly misleading result could arise when chemical alteration occurs after a geomagnetic polarity reversal. The presence of both NRM and a reversed geomagnetic field could result in a single chemical magnetization component nearly perpendicular to the geomagnetic field direction. This mechanism could be a contributing factor in the anomalously shallow palaeomagnetic inclinations often observed in deep drilled marine basalt samples9.

How general are these conclusions? If the direction in which CRM is acquired is partly controlled by magnetostatic interaction with a pre-existing NRM, then the proximity of the parent and daughter magnetic carriers and the intensity of the NRM relative to the external field are critical. If the coupling between the NRM and the CRM is magnetostatic, the moderately high

temperatures used in our experiment will have reduced the influence of the NRM because of the temperature dependence of the spontaneous magnetization of the parent magnetic minerals. In both the low temperature oxidation undergone by submarine basalts and the high temperature alteration of titanomaghaemite which is described here, and which can occur naturally in subaerial basalts10, the parent and daughter magnetic minerals are closely situated and both are strongly magnetic. Thus, in these cases anomalous CRM directions may be common. If CRM is produced in a system where the parent magnetic mineral is essentially non-magnetic such as when magnetite is grown during the serpentinization of olivine, the NRM of the sample as a whole may be of little importance in controlling the CRM direction.

Our present results do not enable us to decide for or against the magnetostatic model of CRM directional control. Current experiments on CRM acquisition during the reduction of weakly magnetic haematite to magnetite may help us resolve this ques-

### Isotopic and biostratigraphical records of calcareous nannofossils in a Pleistocene core

#### Thomas F. Anderson\* & John C. Steinmetz†

- \* Department of Geology, University of Illinois, Urbana, Illinois 61801, USA
- † Department of Marine Science, University of South Florida, St Petersburg, Florida 33701, USA

Knowledge of the species composition is essential for the isotopic record of polyspecific coccolith assemblages in deep-sea sediments to be interpreted properly. We have determined the carbon and oxygen isotopic composition as well as the relative abundance of coccolith species on the 3-25 µm fractions of the Caribbean core P6304-4. The dominant taxon in all samples is well-preserved Gephyrocapsa spp. Oxygen isotope variations clearly define glacial-interglacial oscillations. Except in the upper part of the core, carbon isotopic compositions are not related to the oxygen isotope stratigraphy. The occurrence of three coccolith datum levels in the core correlates almost exactly with globally-synchronous horizons1. The amplitude of the coccolith  $\delta^{16}$ O record (2.4%) is significantly greater than that for the planktonic foraminifera Globigerinoides sacculifer in P6304-4 and adjacent cores<sup>2-4</sup>. We suggest here that selective dissolution or deep calcification during interglacials reduced the amplitudes of G. sacculifer in these cores and that the coccolith record is a more reliable indicator of temperature and  $\delta^{18}O$ changes in surface seawater.

Calcareous nannofossils (dominantly coccoliths) comprise about half of the CaCO<sub>3</sub> in deep-sea sediments<sup>5</sup>. Because of their abundance, shallow and restricted depth habitat<sup>6</sup>, wide geographical distribution<sup>6</sup>, and dissolution-resistant characteristics<sup>7-9</sup>, the stable isotope record of calcareous nannofossils

should complement other techniques in palaeooceanographic investigations.

The oxygen and carbon isotopic composition in coccolith-rich fractions from sediments ranging in age from Upper Cretaceous to Recent have been used as indicators of sea-surface conditions 10-17. Results suggest that coccolith fractions yield isotopic records which are generally consistent with data on foraminifera for the same time interval (and often on the same core material). Nonetheless, a major problem remains in interpreting coccolith isotopic compositions: because of their very small size, coccoliths can only be concentrated from deep-sea sediments as polyspecific assemblages. Because species-dependent nonequilibrium isotopic fractionation in coccolith secretion has been demonstrated<sup>18,19</sup>, it is possible that variations in species abundance will obscure the palaeoenvironmental significance of the isotopic signal from coccolith assemblages. To evaluate this possibility and to test the usefulness of coccolith isotope stratigraphy in Pleistocene sediments, we have determined the isotopic composition and coccolith taxonomy in the fine-fraction of core P6304-4 from the Caribbean.

Core P6304-4 is one of four long piston cores from the same area of the central Caribbean ( $\sim$ 15° N,  $\sim$ 70° W, 3,930-4,140 m in depth) on which Emiliani<sup>2,3</sup> has reported the oxygen isotope record of G. sacculifer. We separated the 3-25  $\mu$ m fraction of bulk sediment samples taken at 10-cm intervals by settling and short centrifugation techniques<sup>20</sup>. High-resolution light microscopy and scanning electron microscopy were used to estimate

the relative abundance and state of preservation of 34 coccolith species. Details of our taxonomic data will be given elsewhere (T.F.A. and J.C.S., in preparation). These results indicate that the carbonate fraction in the 3–25 µm fractions consists almost exclusively of well-preserved coccoliths. The most abundant taxon at all depths was the genus Gephyrocapsa; G. caribbeanica and G. oceanica were dominant (Fig. 1). Emiliania huxleyi, an abundant species during the past 270,000 yr (refs 1, 21), was absent or rare in our 3–25 µm fractions (but was abundant in the bulk sediment samples). Because of its relatively small size, E. huxleyi was not retained in the 3–25 µm fraction. Total (coccolith) carbonate makes up only 10–50% of this fraction. X-ray diffraction analysis indicates that the non-carbonate portion consists of quartz, chlorite and/or kaolinite, mica (illite?) with occasional feldspar and smectite.

The samples were treated with 100% H<sub>3</sub>PO<sub>4</sub> at 25 °C to evolve CO<sub>2</sub> for mass-spectrometric isotope analysis. Pretreatment consisted of soaking the bulk sediment in a 5% clorox solution before size fractionation. The samples were not vacuum roasted as initial experiments indicated that this did not improve the precision of replicate analyses ( $\pm 0.04$  for  $\delta^{13}$ C),  $\pm 0.06$  for  $\delta^{18}$ O) nor alter significantly the isotopic composition of these coccolith fractions. The mass-spectrometric data are reported in  $\delta$ -terminology as % deviations from the PDB standard<sup>22</sup>.

The oxygen isotope results show the characteristic 'saw-toothed' pattern of glacial-interglacial oscillations down to at least isotope stage 14 (Fig. 1). The sharp glacial-to-interglacial

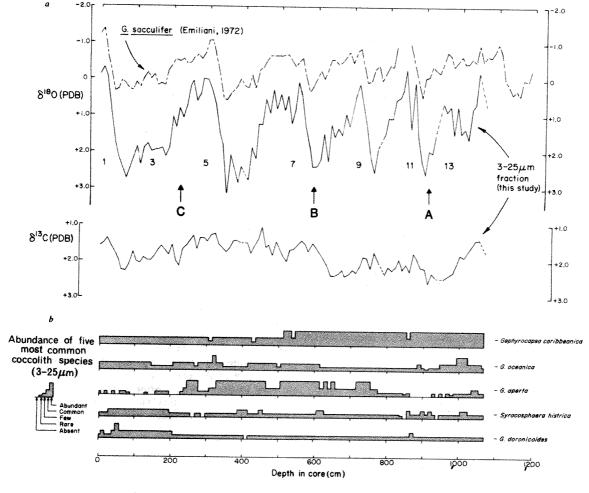

Fig. 1 The oxygen and carbon isotopic results on the 3-25 μm fraction of core P6304-4. Emiliani's² oxygen isotope data on G. sacculifer is also shown. The numbers beneath the 3-25 μm δ¹8O curve identify the interglacial isotopic stages³. In a, A, B and C indicate the globally-synchronous late Quaternary coccolith datum levels of Thierstein et al.¹. A, extinction of Psuedoemiliania lacunosa (458,000 yr BP) at 910 cm; B, first appearance of E. huxleyi (263,000 yr BP) at 590 cm; C, reversal in dominance of G. oceanica and E. huxleyi (85,000 yr BP in tropical and subtropical cores) at 220 cm. The relative frequency of the five most abundant coccolith species in the 3-25 μm fraction (b) was determined from the examination of about 100 fields of view on smear slides⁴5. Abundant, 10-100 specimens per field of view; common, 1-10 specimens per field of view; few, single specimen in 1-10 fields of view; rare, single specimen in 10-100 fields of view.

transitions are well-defined. These stage boundaries in the coccolith fraction occur 10 ( $\pm 15$ ) cm lower than in Emiliani's G. sacculifer record<sup>2</sup>. Given that this difference is about the same as our sampling resolution, the agreement is excellent. In addition, the occurrence of three coccolith biostratigraphic markers relative to the coccolith  $\delta^{18}$ O curve is in almost exact agreement with their correlation in nine other deep-sea sediment cores to the late Quaternary oxygen isotope chronostratigraphic framework<sup>1,23</sup>. The agreement is slightly better for the coccolith record than for the foraminifera record. This correlation between biostratigraphic and isotopic results is convincing evidence for the reliability and precision of the stratigraphical information in the  $\delta^{18}$ O record of coccoliths.

Variations in the carbon isotopic composition of the coccolith fraction (+1.1 to 2.6%) are not obviously related to the oxygen isotope signal. A possible exception is in the interval of the most recent deglaciation, where  $\delta^{13}$ C values decrease by 0.8% from the Upper Pleistocene to the Holocene. A similar carbon isotope shift is recorded in planktonic foraminifera from the Caribbean core V12-122<sup>24</sup>. These results suggest upwelling of nutrient- and  $^{12}$ C-rich waters was higher in the Caribbean during the Holocene than during the last glacial maximum; this is opposite to changes in vertical circulation inferred from carbon isotope evidence in cores from the eastern subtropical Atlantic<sup>25</sup> and the western equatorial Pacific<sup>14</sup>.

Notwithstanding the obvious similarity in isotopic stratigraphy, there are two prominent differences between the  $\delta^{18}$ O signals of the coccolith fraction and G. sacculifer in core P6304-4. First, coccoliths are enriched in <sup>18</sup>O relative to G. sacculifer by 1 to over 2%. Part of this discrepancy could be due to differences in standard calibrations and sample preparation techniques between laboratories. On the other hand, this difference is consistent with data on oxygen isotopic fractionation in these taxa. G. oceanica grown in culture experiments is enriched in <sup>18</sup>O with respect to equilibrium <sup>19</sup>. The question of whether G. sacculifer deposits its test at oxygen isotope equilibrium with near-surface seawater has not been resolved. G. sacculifer assemblages from well-preserved Holocene sediments are often close to isotopic equilibrium 2-4,14,26,27 In contrast, living G. sacculifer populations collected in plankton tows are depleted in <sup>18</sup>O relative to isotopic equilibrium with ambient seawater<sup>24,28-31</sup>. In either case, provided that the isotopic properties of G. oceanica are representative of the coccolith fraction in P6304-4, then the direction of the difference in  $\delta^{18}$ O between this fraction and G. sacculifer is reconciled. (Comparable differences between coccoliths and planktonic foraminifera have been reported previously 13-16.)

Second, the amplitude of glacial-interglacial fluctuations averages 2.4% for the coccolith fraction through stage 12 but only 1.2% for G. sacculifer. Inasmuch as this shallow-dwelling foraminifera occupies the same approximate depth habitat as coccolithophores<sup>26,27,32</sup>, both carbonate constituents should

have been exposed to the same temperature and oxygen isotope composition of seawater during climatic cycles and therefore should have recorded the same  $\delta^{18}$ O fluctuations. Obviously the isotopic record of one (or perhaps both) of these carbonates has been affected systematically by one or more other factors such as variations in non-equilibrium isotope fractionation, changes in depth habitat, and isotopic bias due to selective dissolution<sup>33</sup>.

It is possible that changes in the abundance of the most common species contributed to the glacial-interglacial  $\delta^{18}$ O fluctuations of the coccolith fraction. Our taxonomic study proves that they did not (Fig. 1). Gephyrocapsa is the dominant taxon in the 3-25 µm fraction throughout the core. There is no obvious correlation between the abundance of the most common species of this genus, G. caribbeanica, G. oceanica, and G. aperta (and the next most abundant taxa) and the  $\delta^{18}$ O signal of this fraction. Variation in depth habitat of coccolithophores between glacial and interglacial times is implausible. For this effect to operate, coccolithophores would have had to migrate to deeper waters during glacials. However, as they are photosynthesizers their depth habitat is restricted to the photic zone regardless of climate-induced changes in the physical properties of surface seawater. For the same reason, selective dissolution of coccoliths (for which there is no evidence in our samples) would not result in a bias towards an <sup>18</sup>O-enriched sediment assemblage as it often does in shallow-dwelling planktonic foraminifera<sup>27,32-34</sup>. The effect of differences in seasonal temperature contrast between glacial and interglacial times on the  $\delta^{18}$ O record of coccoliths is difficult to evaluate but was probably not of major importance. Temperature estimates based on quantitative faunal analyses 35-37 suggest that seasonal contrasts during glacials (4-5 °C) was greater than during interglacials (1-2 °C) due to greater variations in winter temperatures. The corresponding maximum seasonality effect on the  $\delta^{18}{\rm O}$  range of coccoliths (secretion during glacial winters and interglacial summers) would be  $\sim +0.4\%$ . The actual seasonality influence was probably much smaller. These considerations suggest that the oxygen isotope variation in the coccolith fraction from P6304-4 records primarily climate-induced fluctuations in the temperature and isotopic composition of Caribbean surface seawater.

If this is correct, then the amplitude of the  $\delta^{18}$ O signal in G. sacculifer from P6304-4 has been truncated. The isotopic record of G. sacculifer in other Caribbean cores analysed by the University of Miami<sup>2-4</sup> are generally consistent with the results on P6304-4 (Table 1, columns 1-6). However, the amplitudes of the  $\delta^{18}$ O signal in the five deeper cores (>3,900 m), including P6304-4, are smaller than the amplitudes recorded in two shallower cores (<3,000 m). This difference in amplitude is due mostly to less negative interglacial  $\delta^{18}$ O values in the deeper cores versus the shallower cores. The amplitude of the coccolith isotope signal in P6304-4 (2.4%) is more compatible with the results from V12-122. In fact, the  $\delta^{18}$ O signal predicted from

the isotopic and faunal temperature data on this core<sup>35</sup> together with experimental fractionation results on Gephyrocapsa very good agreement with our analyses (unpublished data).

The differences in the oxygen isotope record of G. sacculifer among these Caribbean cores, first noted by Shackleton et al. is not easily explained. The relationship between  $\delta^{18}$ O amplitude and depth would suggest that selective dissolution of G. sacculifer during interglacial epochs resulted in a variable proportion of <sup>18</sup>O-enriched tests in the carbonate fraction from which the samples were picked. Shackleton and Opdyke<sup>23,38</sup> report a similar relation between the  $\delta^{18}$ O record of G. sacculifer and depth in two cores from the western equatorial Pacific. However, differential dissolution causing a significant increase in the  $\delta^{18}$ O of G. sacculifer should also have been obvious in the state of preservation of the coccoliths (J. S. Killingley, personal communication). In addition, poor preservation of foramineral assemblages and low carbonate contents in Quaternary Caribbean and equatorial Atlantic cores are more pronounced during glacial than interglacial stages<sup>39-42</sup>. An alternative explanation may involve glacial-interglacial differences in the range of depth habitats and hence the mean temperature of test secretion 31,42-44. For example, Duplessy et al. 31 have reported recently that late-stage calcification of G. sacculifer during descent into cold waters significantly enriches fossil tests in <sup>18</sup>O relative to their living counterparts and note that this effect can produce sedimentary assemblages coincidentaly close to isotopic equilibrium with near-surface seawater. We emphasize that oxygen isotopic variations in Pleistocene coccoliths not only provide an excellent stratigraphic record but also may be a more reliable indicator of the temperature and  $\delta^{18}$ O of surface seawater than planktonic foraminifera. In fact coccolith  $\delta^{18}$ O variations may prove to be important for evaluating the extent and effects of the dissolution and/or deep-water calcification of planktonic foraminifera.

We thank Dr C. Emiliani for sediment samples from core P6304-4, and L. Westgate, K. Marsaglia and K. Coon for technical assistance. This research was supported in part by NSF grants OCE79-13233 and EAR78-22747.

# Extensive regulatory capabilities of a *Drosophila* imaginal disk blastema

#### Gary H. Karpen\* & Gerold Schubiger

Department of Zoology, University of Washington, Seattle, Washington 98195, USA

Every organism develops body patterns that are accurately repeated among individuals of the same species. To understand how cells interact to form these patterns, many investigators have studied the re-establishment of patterns following genetic and/or physical perturbations. In regulating systems, missing structures may be replaced by cell proliferation (epimorphosis) or by respecification without growth (morphallaxis)1. Epimorphosis involves the formation and growth of a blastema<sup>2</sup>, defined for vertebrate regeneration as a zone of proliferating cells, localized near the wound surface3, which becomes capable of regenerating even when isolated from the rest of the limb4. Clonal analysis of Drosophila imaginal disk fragments indicates that during pattern regulation most dividing cells are located near the wound surface<sup>5</sup>. Furthermore, mitotic figures (L. C. Abbott, personal communication) and cells incorporating <sup>3</sup>Hthymidine<sup>6</sup> are clustered near the wound surface of regulating fragments. Here we describe experiments involving cultures of this zone of proliferating cells, and report that it can regulate in isolation. These observations provide evidence that regulation of disk fragments is accomplished by growth of a blastema. Surprisingly, the isolated blastema regenerated more pattern elements than predicted by the polar coordinate model7. We resolve this paradox by proposing that regulation is initiated at free cut edges, where a blastema is formed that adds new positional values in a sequence. On completion of wound healing, blastema growth continues until remaining positional disparities are eliminated by intercalation, as presented in the polar coordinate model.

We used the property that imaginal disk tissue differentiates when transplanted into a metamorphosing larva to determine the fate of particular first leg disk regions (Fig. 1a, b). The three-quarter lateral plus endknob fragment (3/4L+EK)differentiated sectors A, B, C and D plus the tarsus. This region of the disk was subdivided into the 1/8LM and 5/8L+EK fragments, which produced sector D and sectors A, B and C plus the tarsus, respectively. Figure 1c gives the sectorized fate map of the disk obtained by pooling results from different fragments. The growth period of disk tissue is extended by transplantation into the abdomen of an adult female (culture in vivo). When 3/4L+EK fragments were cultured in adults and then differentiated in larval hosts, they usually duplicated the structures found in the fate map of the fragment (Fig. 1d). The 1/8LM fragment did not regenerate after 6 days in adult culture. An unusually high number of implants were not found (38/62), and the 11 differentiated implants only contained structures seen in the fate map of the fragment.

When the 3/4L fragment duplicates, the prospective sector D contains a zone of proliferating cells<sup>5</sup>. We isolated this area fragment I from 3/4L+EK fragments after 1 day of adult culture (Fig. 2a). The position of the nerve stalk and the

Fig. 1 a, Structures differentiated by the first leg disk. To visualize all the adult structures the leg is displayed as if split open longitudinally. Disks differentiated all the segments and structures found in an in situ prothoracic leg. Donors and hosts (La) were late third-instar larvae. We divided the leg cuticle into sectors A-F to facilitate discussion of the results (see ref. 14 for a complete description of the markers). Each sector contained a minimum of two sector-specific markers. Pt = prothorax, Co = coxa, Tr = trochanter, Fe = femur, Ti = tibia, Ta 1 = first tarsal segment, Ta 2-5 = tarsal segments 2-5.\* Denotes position of the nerve stalk. Solid arrowheads symbolize metamorphosis. b, Fate mapping of disk regions. L = lateral, LM = lower medial, EK = endknob. The height of each column indicates the percentage of the cases that differentiated the particular sector. c, Sectorized fate map of first leg disk. d, Adult culture of 3/4L+EK fragments. Fragments were injected into the abdomens of fertilized, recently eclosed females (Ad); after 4 days of culture in vivo implants were transplanted into larval hosts. Reversed letters indicate duplicate sectors. Forty per cent of the 3/4L+ EK fragments only duplicated structures expected from the fate map, 53% also regenerated sector E and 7% only regenerated sector E, without duplicating any structures.

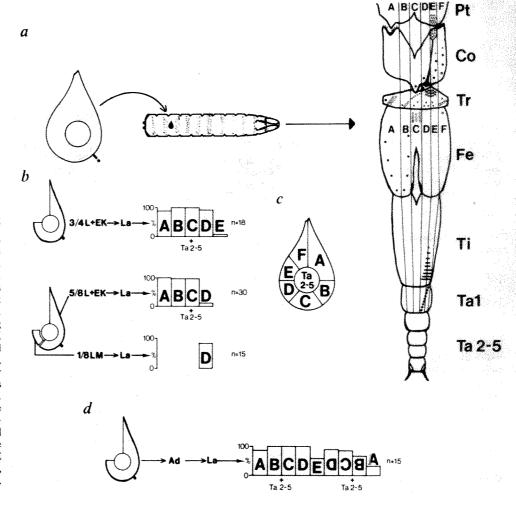

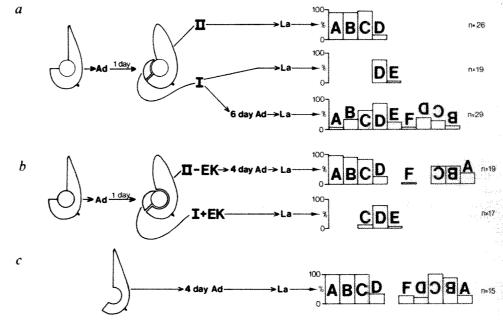

Fig. 2 a, Regulatory potential of the blastema region. 3/4L+EK fragments were cultured in vivo for 1 day; the implants were then cut into fragments I and II. Immediate metamorphosis was used to determine the fate of the II fragments. Only 15% of these cases differentiated sector D, whereas over 90% produced sectors A, B and C and Ta 2-5. I fragments were either injected into larval hosts or given an additional 6 days of adult culture before metamorphosis. Ta 2-5 appeared only after culture in vivo (in 21% of the cases). b, Regulatory potential of the II-EK fragment. 3/4L+EK fragments were cultured in vivo for 1 day, then I+EK fragments were injected into larval hosts while II-EK fragments were given another 4 days of adult culture before metamorphosis. Ta 2-5 were

differentiated by 94% of the I+EK fragments and 37% of the II-EK fragments. Forty-two per cent of the II-EK fragments only duplicated sectors A, B and/or C, 32% also regenerated sectors D and/or F, and 5% only regenerated sector D and/or F. II-EK fragments were used (instead of II fragments) to allow a direct comparison with the I fragment, which also did not include the endknob. Four days of culture were chosen to reduce the high frequency of transdetermination found in this fragment after 6 days of culture. c, Adult culture of 5/8L fragments. Fragments were given 4 days of adult culture before metamorphosis. Fifty-four per cent only duplicated sectors A, B and/or C, and 46% also regenerated sectors D and/or F. Ta 2-5 were differentiated by 60% of the cases. See Fig. 1 legend for a description of symbols.

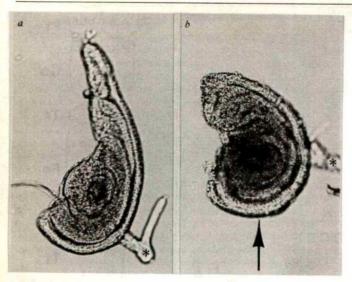

Fig. 3 3/4L+EK fragments immediately after fragmentation (a) and after 1 day in vivo culture (b). ×178. \* Denotes nerve stalk, arrow indicates position of second cut (see Fig. 2b). Note in b that the original cut surfaces have not fused.

presence of unfused cut surfaces facilitated orientation of the implants (Fig. 3). Immediate metamorphosis of fragment I yielded structures of sector D, but never sector C. The remaining piece (fragment II) predominantly differentiated sectors A, B and C plus the tarsus (Fig. 2a).

We determined the regulatory capabilities of regions within the 3/4L+EK fragment after 1 day of culture in vivo. I fragments were isolated, then given an additional 6 days in adult hosts (Fig. 2a). Although the amount of regulation varied, these fragments differentiated identifiable and organized patterns. Most (18/29 cases, 62%) contained structures that were never formed by uncultured I fragments (sectors A, B, C and/or F). Thirteen of these cases duplicated some or all of the structures present (for examples, see Fig. 4, cases 4 and 5). We also analysed these data in a pairwise manner to determine whether these surprising results were caused by cutting errors. Figure 4 shows cases in which both the I and II fragments from a single 3/4L+EK implant differentiated. In cases 1-3, fragment I produced sector D and showed some regeneration. In all the other paired cases I fragments extensively regenerated missing structures. They contained structures also found in the II fragment of the pair (boxed sectors), and in addition were able to differentiate structures that were not part of the 3/4L+EK fate map (sector F, cases 6-8). In case 8 the I fragment produced an entire leg! Thus, we conclude that the I fragments regenerated during culture in vivo.

II-EK and 5/8L fragments differentiated the same structures after transplantation into larvae (sectors A, B and C, data not presented) and therefore have the same fate. After 4 days in adults they regulated similarly; most cases duplicated and some of these fragments also regenerated (Fig. 2b, c). In contrast, the I and 1/8LM fragments had the same fate (sector D, Figs. 2a,1b), but only the I fragment regenerated after 6 days of adult culture. Therefore, during 1 day of culture in vivo of the 3/4L+EK fragment the regulative potential of only prospective sector D cells was altered. Furthermore, clonal analysis indicated that cell divisions increased significantly during regulation only in sector D of the 3/4L fragment<sup>5</sup>. We conclude that during 1 day of adult culture a blastema is formed in this region, and we propose that blastema formation and growth are integral steps in the regulation of disk fragments.

The extensive regulatory capabilities of the blastema region challenge current explanations of how imaginal disk fragments regulate. According to the polar coordinate model<sup>7</sup>, wound healing juxtaposes cells with disparate positional values; this stimulates growth, and intercalation proceeds until positional values are continuous. The 'rule of intercalation by the shortest

route' predicts the type of regulation a particular fragment will express. A fragment containing more than half the total number of positional values regenerates, whereas a fragment with less than half the values will only duplicate. The isolated blastema fragments violate two aspects of this rule. First, many I fragments were able both to regenerate and duplicate, which is inconsistent with the model<sup>8,9</sup>. Second, the I fragments consistently regenerated missing structures, and produced an entire leg in two of the cases given 6 days additional culture in vivo, although they contained few positional values. When the 3/4L + EK fragment was cultured in vivo for 1 day, on immediate metamorphosis no I fragment duplicated structures, and only 5% differentiated sector E in addition to D (Fig. 2a). According to the positional value map of the first leg disk<sup>10</sup>, sectors D and E contain much less than half the number of circumferential positional values.

A possible resolution of this problem is suggested by comparing the time course of wound healing with our data. An imaginal disk consists of a folded sheet of columnar epithelial cells and an overlying sheet of squamous epithelial cells (peripodial membrane), which form a continuous epithelium<sup>11</sup>. Reinhardt and Bryant<sup>12</sup> have shown that within 12 h of fragmenting a wing disk, the columnar epithelial cells at each cut surface make contact with cells of the peripodial membrane (heterotypic healing). By 1–2 days after fragmentation, columnar epithelial cells from the previously separated cut edges fuse (homotypic healing). The polar coordinate model<sup>7,12</sup> suggests that homotypic contacts initiate and control pattern regulation. However, we isolated blastemas with extensive regulative capacities before wound healing was complete, and therefore conclude that homotypic closure is not necessary for the initiation of regulation.

Two independent observations support this conclusion and further characterize the early blastema. First, mitotic figures are localized to the blastema region of the 3/4L+EK fragment within 1 day of adult culture (L. C. Abbott, personal communication). Thus, proliferation is stimulated before wound healing is complete. Second, in many regulating leg disk fragments new structures appear in a sequence that originates from the cut surface containing the blastema<sup>5,13</sup>. This same sequence

Fig. 4 Pairwise analysis of the regulatory potential of the presumed blastema area. 3/4L+EK fragments were cultured for 1 day in vivo; the implants were then cut into fragments I and II. I fragments were given an additional 6 days in adults before metamorphosis, whereas II fragments were injected into metamorphosing hosts. I and II fragments from the same 3/4L+EK implant were analysed in a pairwise manner. +, Sector present; -, sector absent; ++, sector present and duplicated. Sector considered present when two or more markers were identified. (+), One marker identified. Boxes indicate that the same structures were differentiated by both fragments. Underlined sectors indicate those clearly regenerated.

is followed by isolated blastemas. Figure 2a shows that I fragments cultured in adults for 6 days regenerated and/or duplicated sector B less frequently than sectors C and D. This sequence also is expressed in each case that regulates. For example, when sector B was regenerated, sector C was always present. Therefore, the information necessary for regulating, in a sequence, is present before the completion of wound healing.

Later in the regulative process, homotypic healing is completed and cells at the cut edge are confronted with new neighbours. We propose that blastema growth continues, and additional positional values are intercalated according to the shortest route, as expressed in the polar coordinate model. This proceeds until continuity is restored to the positional field.

Our study indicates that stimuli other than homotypic wound closure, such as heterotypic contacts or simply the presence of a free cut edge, could initiate regulation. We do not know what types of interactions initially determine whether a blastema will regenerate or duplicate. However, we hope our study stimulates new thoughts about how cells interact during pattern formation.

### Estimates of dinosaur speeds from a new trackway site in Texas

James O. Farlow

255 West Twenty-First Street, Holland, Michigan 49423, USA

A method for estimating the speed of a dinosaurian trail-maker from the size of its footprints and stride has been described by Alexander1. However, when applied to known trackways, this method gave rather low speeds (1.0-3.6 m s<sup>-1</sup>). Russell and Béland<sup>2</sup> estimated a speed of 1.77 m s<sup>-1</sup> for a slowly moving ornithomimid and 7.54 m s<sup>-1</sup> for an allegedly rapidly running ornithopod. The latter estimate is questionable as there is some doubt concerning the number of prints (and thus the stride length) of the trail<sup>3,4</sup>. Dinosaurs responsible for trackways in British Columbia<sup>5</sup>, South Wales<sup>6</sup> and Queensland<sup>7</sup> all seem to have been moving slowly. Thus reliable estimates of dinosaur speeds are all rather low. Here I report dinosaur speeds based on trails at a new site from the Lower Cretaceous of Texas, some of which appear quite fast by Alexander's method1.

The site lies along Middle Copperas Creek in western Kimble County, Texas, on the F6 Ranch. The tracks occur in the lower third of an approximately 1-metre-thick, thin-bedded, very fine-grained limestone. Rock layers containing footprints are exposed in a narrow belt on either side of the creek bed. The limestone is heavily mud-cracked, and in some places ripple marks are preserved. The precise stratigraphical level of the locality is uncertain; the track-bearing unit is in either the lower Fort Terrett Formation or the upper Glen Rose Formation (US Gulf Coast age is Comanchean; European age equivalent of the relevant part of the Comanchean is Aptian-Albian).

All the F6 Ranch tracks seem to have been made by carnivorous dinosaurs (theropods) of various sizes. Trackway data are given in Table 1. A stride is taken as the distance between corresponding points on successive prints of the same foot; a pace is the distance between corresponding points on successive prints of the opposite feet, or half a stride. The larger the number of tracks in a trail, the more accurate will be the speed estimated from that trail. The estimated speeds of the F6 Ranch theropods range from 1.8 to 11.9 m s<sup>-1</sup>. Most of the speeds are within the range reported previously, but three are considerably faster (Fig. 1). Alexander indicated that mammals shift from walking to trotting or running when the ratio of stride/hip height reaches 2.0. On this basis, at least five of the F6 Ranch dinosaurs would have been moving with a faster gait than a walk, and the makers of trails 86 → 0-82, BLV → A3 and Q94 → Q98 were probably running.

Alexander et al.8 described a relationship between stride length, animal size and speed, based on observations of rapidly running African ungulates, that they felt to be more appropriate for fast gaits than Alexander's earlier equation. Applying this revised equation results in slightly greater speeds for the three

running dinosaurs (Table 1).

Russell9 suggested on anatomical grounds that ornithomimids could have reached speeds of 22.2 m s<sup>-1</sup>. Applying a formula taken from Bakker<sup>10</sup>, Coombs<sup>11</sup> calculated that some ornithomimids might have attained speeds of 26.9 m s<sup>-1</sup>, and that large theropods like Allosaurus and Tyrannosaurus might have had top running speeds of 12.8-14.7 m s<sup>-1</sup>. However, Coombs expressed doubts as to the reliability of these estimates. Nevertheless, if these estimates of top running speed in theropods are even approximately correct, they suggest that the estimated speeds of the F<sup>6</sup> Ranch running theropods are not unreasonable.

Although there is no obvious relationship between the sizes of the F6 Ranch dinosaurs and their speeds, only the smaller or medium-sized reptiles seem to have been running rapidly. One might expect moderate-sized dinosaurs to have reached greater speeds than their larger contemporaries 11,12, although this has

been disputed13

Coombs<sup>11</sup> concluded that the running abilities of dinosaurs were inferior to those of modern cursorial mammals, a contention that has been both supported12 and challenged 3 by other workers. Human athletes can achieve speeds of 10 m s short distances; greyhounds and horses reach speeds of 19 m s in races14. In the wild, African ungulates have been clocked at speeds of 7-14 m s<sup>-1</sup> (ref. 8), and ostriches may attain speeds of 12-14 m s<sup>-1</sup> (ref. 15). Thus the fastest of the F<sup>6</sup> Ranch theropods were moving at speeds greater than those reached by human athletes, but not as fast as the top speeds of modern cursorial animals. Whether the estimated speeds of the F6 Ranch running

Fig. 1 Three footprints of trail BLV → A3, made by one of the running dinosaurs. Pace lengths for this part of the trail are 271.8 cm (A1 → A2) and 261.6 cm (A2 → A3); stride length, 530.9 cm. Estimated speed of the dinosaur, 8.3 m s

theropods represent their top running speeds is, however, unknown.

I have assumed that the method of Alexander accurately estimates the speeds of dinosaurian trail-makers, but this can probably never be proved. However, the relatively long strides taken by three of the F<sup>6</sup> Ranch dinosaurs suggests that, unless they had unusually long legs, these reptiles were moving faster

# Cytotoxic T lymphocytes induced by syngeneic mouse melanoma cells recognize human melanomas

Seiji Wakabayashi\*, Masaru Taniguchi†, Takeshi Tokuhisa†, Hisao Tomioka‡ & Shoji Okamoto\*

Departments of Dermatology\*, Immunology† and 2nd Internal Medicine‡, School of Medicine, Chiba University, Chiba, Japan

The recognition by T cells of antigens displayed or presented on the cell surface is generally restricted by the products of genes in the major histocompatibility complex (MHC)1. Thus, most cytotoxic T cells recognize antigens in conjunction with self MHC determinants, especially in the response against virusinfected lymphocytes2, chemically modified self antigens3 and tumour cells4. In these situations, the majority of cytotoxic T-cell clones seems to recognize MHC determinants unique to the individual alleles ('private'-type determinants). However, certain cell surface antigens seem not to be subject to such rigid MHC restriction<sup>5-7</sup>. These apparent exceptions could be incorporated into the MHC-restriction model by postulating the involvement of public-type determinants of MHC as restriction site, but until now no cross-killing across species barrier has been reported in these instances. We now report that mouse cytotoxic T cells induced in primary culture by syngeneic melanoma cells killed various human melanoma cell lines in an antigen-specific fashion.

Cytotoxic T lymphocytes (CTL) against syngeneic malignant melanoma cells (B16) were induced in in vitro primary culture of naive C57BL/6 mouse spleen cells with mitomycin C(MMC)treated B16 melanoma cells. The cytotoxic activity was melanoma specific, since the cytotoxic lymphocytes killed only syngeneic melanoma cells (B16) but not C57BL/6 lymphoma (EL-4), C57BL/10 sarcoma (S913) or A/J sarcoma (S1509a) cells. As shown in Fig. 1, the cytotoxic lymphocytes were able to lyse four different human melanoma cell lines (P-22, P-36, P-39, HMV-I) as well as mouse melanoma (B16), while they did not affect the other human cell lines tested—lymphoma (OKU) and cervix carcinoma (HeLa-S3). The cross-reactive cytotoxic activity was completely abrogated by treatment of the cells with monoclonal anti-Thy-1.2 and complement (C). This indicates that the cells responsible for the cross-reactive cytotoxicity have T-cell characteristics (Fig. 2). These results, therefore, clearly show that mouse CTL specific for syngeneic melanoma cells definitely cross-reacted with human melanoma cells, acting across a species barrier.

The cross-reactive specificity of the CTL was confirmed by using a cell inhibition assay, demonstrating that both human and mouse melanoma cells specifically inhibited CTL activity against syngeneic mouse melanoma cells (B16). In this experiment, the activity of the CTL was assayed against 51Cr-labelled B16 melanoma cells. Various unlabelled mouse and human tumour cell lines were added to the assay system as blockers with different cell numbers. The results clearly showed that both mouse and human melanoma cells (B16, P-22, P-36, P-39, HMV-I) but not other tumour cell lines (EL-4, OKU, HeLa-S3) gave strong inhibition of the CTL activity against B16 melanoma (Table 1). The inhibitory effects were specific, since the cytotoxic activity of the EL-4-specific CTL, induced in the in

<sup>†</sup> Estimate based on twice the value of a single pace. ‡ Revised formula for rapid gaits.

vitro primary culture of naive C57BL/6 spleen cells together with MMC-treated EL-4, was blocked by EL-4, but not by the mouse and human melanoma cells which inhibited melanoma-specific CTL (Table 1). Also, the possible involvement of the fetal calf serum component of the culture media as acquired determinants on the target cell surface was excluded, since the cytotoxic activity was observed on and inhibited only by melanoma cell lines from both human and mouse origins and not by other human and mouse tumour cell lines.

Thus our results show that malignant melanoma cells carry specific antigenic determinants shared with both mouse and human species—that is, melanoma-specific antigens have common antigenic moieties in different animal species. This is also supported by our finding that cytotoxic antisera raised in C57BL/6 mice hyperimmunized with MMC-treated B16 melanoma cells could specifically react with both mouse and human melanoma cell lines but not other cell lines (data not shown).

In general, the identity of the histocompatibility between T cells and their target cells is necessary for the cytotoxic T-cell

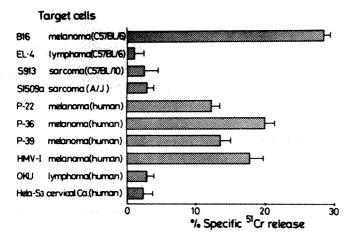

Fig. 1 Cross-reactive cytotoxic effect of mouse melanoma (B16)induced syngeneic (C57BL/6) killer cells on human melanomas. C57BL/6 cytotoxic lymphocytes (CTL) against syngeneic mouse melanoma (B16) cells were induced in the in vitro primary response. In brief,  $3 \times 10^7$  spleen cells from naive C57BL/6 mice were cultured alone as a control or with  $6 \times 10^5$  of MMC-treated B16 melanoma cells in 3 ml Dulbecco's modified minimal essential medium (DMEM) containing 5% fetal calf serum (FCS) and M 2-mercaptoethanol in 3.5 cm × 1 cm Petri dish (Falcon) at 37 °C in humidified 5% CO<sub>2</sub> in air. Five days later, the cells were pelleted by centrifugation and adjusted to  $6 \times 10^6$  viable nucleated cells per ml. To assay the activity of the cultured cells, the lymphoid cells  $(6\times10^5)$  were mixed with  $1.5\times10^4$  <sup>51</sup>Cr-labelled target cells (target/CTL ratio 1:40) in 0.2 ml of DMEM in a multi-well plate (NUNC) in quadruplicate. Target cells were mouse and human cell lines: C57BL/6 melanoma, B16; C57BL/6 lymphoma, El-4; C57BL/10 fibrosarcoma, S913; A/J fibrosarcoma, S1509a; human melanoma cell lines, SK-MEL-26(P-22), SK-MEL-28(P-36), MeWo(P-39), HMV-I; human lymphoma, OKU; and human carcinoma, HeLa-S3. The plates were incubated for 12 h at 37 °C and the radioactivity in a 0.1 ml supernatant from each well was counted by a well-type  $\gamma$  scintillation counter (Dainabot). Per cent lysis was expressed as percentage of specific  $^{51}$ Cr release calculated by the formula:

% Specific 51Cr release

$$= \frac{\text{c.p.m. experimental release} - \text{c.p.m. control release}}{\text{c.p.m. maximum release} - \text{c.p.m. control release}} \times 100$$

Control release was determined by incubating <sup>51</sup>Cr-labelled target cells with naive spleen cells of C57BL/6 mice cultured for 5 days without stimulator cells (B16). Maximum lysis was obtained by disrupting the target cells with saponin (Wako Pure Chemical). The bars indicate arithmetic means of the per cent specific lysis for four cultures ±s.d.

interaction1. In these studies, T cells have been shown to recognize MHC-encoded products, especially determinants that are highly polymorphic within species and those closely related to the serologically defined histocompatibility antigens. Thus, the requirement for T-cell recognition of MHC determinants has been demonstrated on the basis of MHC restriction of the cytotoxic activity. However, there are a few reports that MHC identity is not required for the interaction between cytotoxic T cells and allogeneic target cells<sup>8-10</sup>. For example, Burton et al.<sup>8</sup> have described the primary in vitro responses of murine cytotoxic T cells specific for oncofetal and plasmacytoma antigens that do not appear to be H-2 restricted. Similarly, Shaw et al. have demonstrated that the human cytotoxic T cell induced by trinitrophenol (TNP)-modified autologous cells was not restricted to lysis of TNP-modified human target cells without carrying shared HLA determinants with targets, and that the human CTL raised against TNP-self was clearly restricted with respect to lysis of mouse target cells. Nevertheless, these apparent exceptions could be explained by the MHC-restriction model that T cells recognize antigens in association with MHC determinants being widely shared within species.

However, the results presented have failed to show MHC restriction, and CTL specific for syngeneic mouse melanoma killed human melanoma cell lines across a species barrier. The products of genes in the I-E/I-C but not I-A subregion of the mouse H-2 complex share interspecies cross-reactive determinants with human HLA-DR antigens11,12, and human melanoma cell lines have also been reported to express HLA-DR like antigens 13,14. Thus the cross-reactive DR or Ia antigens are possible candidates to serve as 'self' determinants recognized by CTL. However, C57BL/6 mice as used in our studies have been shown not to express I-E/I-C subregion gene products<sup>11</sup>, so the B16 melanoma of C57BL/6 origin seems not to express cross-reactive Ia antigens on the cell surface. It is likely, therefore, that the CTL recognizes the melanomaspecific antigen itself, rather than an association of the antigen with MHC determinants. If so, the MHC restriction in the T-cell response may be determined by the nature of antigens with or without MHC products. If, however, common MHC determinants are conserved in different animal species (at least between mouse and man), it is also possible that mouse CTL recognizes melanoma-specific antigenic determinants in association with such conserved MHC determinants on human melanoma cells. We cannot yet determine whether one or more of these alternatives operate in tumour immunity, and experiments are under way to look into this question.

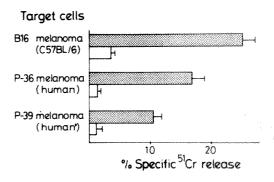

Fig. 2 Effect of the treatment with anti-Thy-1.2 on the cytotoxic activity of B16-induced syngeneic (C57BL/6) killer cells against mouse and human melanomas. The C57BL/6 CTL induced by syngeneic mouse melanoma cells (B16) as described in Fig. 1 was treated with a 1:1,000 dilution of monoclonal anti-Thy-1.2 (F7D5) for 30 min at 37 °C followed by incubation with well selected rabbit complement at 37 °C for 45 min. The activity of CTL treated was assayed by the same method as described in Fig. 1 legend. The bars indicate arithmetic means of the specific lysis of four cultures ±s.d. Solid and open bars indicate the activity of the CTL treated with complement alone or that treated with anti-Thy-1.2 and complement, respectively.

Table 1 Specific inhibitory effects of human melanoma cells on the cytotoxic activity of C57BL/6 killer T cells specific for B16 melanoma cells

		% Specific <sup>31</sup> Cr release			
Inhibitor cells	Labelled/unlabelled cell ratio	C57BL/6 anti-B16 on B16 melanoma	C57BL/6 anti-EL-4 on EL-4 lymphoma		
None	washin.	$23.9 \pm 1.2$	$34.3 \pm 2.2$		
B16 melanoma (C57BL/6)	1:9	$6.3 \pm 0.6$	$32.8 \pm 2.1$		
EL-4 lymphoma (C57BL/6)	1:9	$24.1 \pm 1.2$	$9.0 \pm 1.4$		
P-22 melanoma (human)	1:9	$3.2 \pm 1.2$	ND		
P-36 melanoma (human)	1:9	$5.0 \pm 1.4$	$26.6 \pm 2.1$		
P-39 melanoma (human)	1:9	$7.2 \pm 1.0$	$27.5 \pm 2.0$		
HMV-I melanoma (human)	1:9	$2.1 \pm 1.0$	ND		
OKU lymphoma (human)	1:9	$22.4 \pm 0.3$	ND		
HeLa-S3 carcinoma (human)	1:9	$20.4 \pm 0.9$	ND		

The activity of the C57BL/6 CTL-induced B16 melanoma or EL-4 lymphoma was assayed as described in Fig. 1 legend on 51Cr-labelled B16 or EL-4 tumour target cells (target/CTL ratio 1:40), respectively. Various unlabelled mouse and human tumour cell lines were added to the assay system as blockers with different cell numbers (labelled/unlabelled = 1:0, 1:1, 1:3, 1:9). The assay conditions and tumour cell lines were the same as described in Fig. 1 legend. The absolute number of the CTL and  $^{51}$ Cr-labelled B16 melanoma or EL-4 lymphoma cells as targets remained constant (target/CTL ratio of 1:40). Only blocker cell number was varied. Results are expressed as arithmetic means of the specific lysis of four cultures ±s.d.; ND, not determined.

We thank Drs S. Fujimoto, T. Kasuga, T. Kuwata, N. Kashiwagi and T. Takahashi for supplying mouse or human tumour cell lines and Dr P. Lake for mouse monoclonal anti-Thy-1.2. We also thank Dr N. Shinohara for his criticism and Miss Hisano Nakajima for secretarial assistance.

# **Antigen-driven helper** cell-independent cloned cytolytic T lymphocytes

Michael B. Widmer & Fritz H. Bach

Immunobiology Research Center, Box 724 Mayo Memorial Building, University of Minnesota, Minneapolis, Minnesota 55455, USA

Cellular interactions between alloreactive cytolytic T lymphocytes (CTLs) and helper T cells have been suggested by the results of experiments in which lymphocyte subpopulations were defined by antisera against cell-surface markers' or by differential response to antigenic stimulation<sup>2,3</sup>. The development of T-cell cloning technology has allowed the isolation of alloreactive cloned helper and cytolytic cells, and the demonstration of collaboration between them in the generation of cytotoxicity<sup>4,5</sup>. Whereas some types of alloantigen-specific cloned T cells, including helper cells, proliferate in tissue culture in response to antigenic stimulation<sup>4-8</sup>, CTLs isolated thus far do not and require for proliferation the addition of exogenous T-cell growth factors (TCGFs) or helper cells which produce TCGF in response to antigenic stimulation<sup>4,5,7-10</sup>. We demonstrate here, at the clonal level, the existence of another type of CTL which proliferates in response to allogeneic stimulating cells without the overt addition of TCGF; it produces helperlike factor and thus can be characterized as a helper cellindependent CTL.

T-cell clones were derived by limiting dilution from 5-day C57BL/6 (B6) anti-DBA/2 (DBA) bulk mixed lymphocyte culture (MLC) populations as previously described<sup>7</sup>. Limiting dilution microcultures for cloning were seeded on day 5 of MLC with  $0.25\,\mathrm{B}6$  anti-DBA cells per well,  $1\times10^6$  irradiated (2,000 rad) DBA spleen cells and 30% (v/v) secondary MLC supernatant (2° MLC SN)11 as a source of growth factors, including TCGF. After 7-8 days, growing clones were further expanded numerically in larger culture vessels in the presence of DBA spleen cells and 20% 2° MLC SN and maintained by subculturing at 5-7-day intervals. Such cloned populations were tested repeatedly for cytolytic activity against P815 (DBA origin) and EL4 (B6 origin) tumour target cells in both direct and lectin-dependent 51Cr release assays and for their ability to proliferate in response to allogeneic DBA stimulating cells.

Table 1 shows the proliferative responses of two cloned CTL populations and two cloned helper populations. Clones 17-11 and 17-4 are CTLs which cause 50% <sup>51</sup>Cr release from P815 target cells in a direct test at effector/target ratios of 1:1 to 3:1; no detectable lysis of EL4 cells is observed at ratios of up to 30:1. Clones 12-11 and 17-10 can be characterized as noncytolytic cells based on their inability to kill P815 or EL4, even in the presence of lectin, and as helper cells based on their ability to produce soluble factor(s) capable of stimulating proliferation in a TCGF assay using long-term (days 14-18), resting, primary MLC populations as indicator cells (unpublished observation).

All clones proliferated in culture when 2° MLC SN was present, regardless of whether splenic filler cells were also present (Table 1). However, in the absence of exogenous 2° MLC SN, only certain clones, such as helper cell clones 12-11 and 17-10, proliferated in response to specific allogeneic DBA stimulating cells. Cultures of CTL clone 17-11 and allogeneic DBA stimulating cells did not incorporate amounts of <sup>3</sup>Hthymidine (TdR, 3,066 c.p.m.) greater than those incorporated in control cultures using syngeneic B6 stimulators (1,048 c.p.m.) or stimulating cells alone (3,736 c.p.m.) (Table 1). This CTL clone thus exhibits the growth requirement for TCGF typical of CTL clones previously described<sup>4,5,7-10</sup>; in our experience, six B6 anti-DBA CTL clones behaved in the proliferative assay like CTL clone 17-11. In contrast, CTL clone 17-4 demonstrates the distinct ability to proliferate in response to allogeneic DBA stimulating cells, even in the absence of 2° MLC SN (23,792 c.p.m.).

None	. 4 Hawari — <mark>—</mark>	NT NT	$1,346 \pm 888$ $1,264 \pm 146$	$3,736 \pm 2,482$ $3,690 \pm 130$

Proliferative response of alloreactive clones in MLC. Clones were derived by limiting dilution from 5-day B6 anti-DBA bulk MLC populations. Cloned cells were expanded and maintained by subculturing  $1-5\times10^4$  cloned cells at 5-7-day intervals in 16-mm Costar wells containing 20% v/v 2% MLC SN and  $6\times10^6$  irradiated (2,000 rad) DBA spleen cells. The culture medium consisted of Dulbecco's modified Eagle's medium supplemented with 2% fetal bovine serum and additional amino acids. For the proliferative assay,  $1\times10^4$  cloned cells obtained 5-7 days after previous subculture were cultured (0.2 ml final volume) in flat-bottom microtitre plates either alone or with  $1\times10^6$  irradiated syngencic B6 or allogencic DBA spleen cells in the presence or absence of 25% 2° MLC SN. Cultures were pulsed on day 2 for 7 h with 2  $\mu$ Ci  $^3$ H-TdR. Cells were collected on to glass fibre filters and  $^3$ H-TdR incorporation was determined by liquid scintillation spectrometry. Results are given as mean c.p.m.  $^3$ H-TdR incorporated  $\pm$  s.d. of triplicate cultures. NT, not tested.

Because cells of putative clone 17-4 exhibited the lytic characteristics of CTLs and the proliferative characteristics of T-helper cells, we investigated whether both functions were in fact mediated by the progeny of a single cell, rather than two functionally distinct cells contained within the 17-4 population, by analysing subclones derived from 17-4 cells in both the cytolytic and proliferative assays. Subcloning was accomplished by plating 17-4 cells in limiting dilution microcultures at a concentration of 0.1 cells per well. Of 168 microcultures established, 20 were observed to contain growing cells when examined microscopically 7 days after culture initiation. Thus, cells from putative clone 17-4 had 100% plating efficiency (16 positive microcultures were expected based on the Poisson distribution). Cells from five positive subcloning cultures were picked, expanded numerically and tested for both cytolytic activity against P815 and proliferation in response to irradiated DBA spleen cells. Figure 1 demonstrates that cells of parent clone 17-4 and all five tested subclones were highly cytolytic towards P815 target cells, causing 50% <sup>51</sup>Cr release at effector/target ratios between 1.8:1 and 3:1. In addition, cells of all five 17-4 subclones were, like those of the 17-4 parent clone, able to proliferate in response to irradiated DBA spleen cells in the absence of overtly added 2° MLC SN (Table 2). The probability that any one of these subclones could have been derived by chance alone from more than one cell in the parental population of putative clone 17-4, given the 0.1 cell per well dilution used for subcloning, is  $5 \times 10^{-2}$ ; the probability for all five subclones is  $3 \times 10^{-7}$ . Thus, there can be no reasonable doubt that both cytolytic activity and proliferative response to allogeneic cells are in this case functions of the progeny of a single T cell. Karyotypic analysis of 17-4 cells has shown them to have the normal chromosome number of 2n = 40.

The proliferative response of cells of clone 17-4 in the presence of allogeneic stimulating cells could conceivably be induced by factors secreted by cells, presumably T cells, within the irradiated stimulating cell population, which recognize the cloned cells as foreign—that is, by 'back stimulation'. However, the data in Table 3 demonstrate that allogeneic cells depleted of T cells by pretreatment with anti-Thy-1.2 antibody and complement stimulate cells of subclone 17-4.24 to proliferate,

Proliferative response in MLC of CTL clone 17-4 and its subclones. Subclones were derived by plating 17-4 cells at a concentration of 0.1 cells per well in the presence of  $1 \times 10^6$  irradiated DBA spleen cells and 30% 2° MLC SN. Cloned cells were expanded, maintained and tested for proliferative responses in MLC as described in Table 1 legend.

Table 3 Proliferative response of cloned cells to T-cell-depleted stimulating cells

Proliferative response of subclone 17-4.24 to T cell-depleted stimulating cells. Cloned cells were tested for proliferation in response to allogeneic spieen cells in the absence of 2° MLC SN as indicated in Table 1. Syngeneic B6 or allogeneic DBA spleen cells were incubated at room temperature for 30 min with a 1:1,000 dilution of monoclonal anti-Thy-1.2 antibody (NEN), followed by incubation at 37 °C for 45 min with a 1:10 dilution of rabbit complement (C'). Control aliquots were incubated with complement alone. Antibody and control-treated cells were washed three times, irradiated (2,000 rad) and used as stimulating cells ( $1 \times 10^6$ cells per culture) in MLC with cloned responding cells.

thus eliminating back stimulation as the sole or primary explanation for the proliferative response. In addition, specificity analyses using congenic H-2 recombinant strains have shown specificity of clone 17-4 in both the proliferative and cytotoxic assays against D<sup>d</sup>-encoded antigens; no proliferative response (and thus no back stimulation that might be expected) is observed even when cells from strains bearing entirely different H-2 antigens (H-2<sup>s</sup> and H-2<sup>k</sup>) are used as potential stimulators of 17-4 cells.

We have shown here, on the clonal level, that alloreactive CTLs can be divided into at least two distinct categories based on their requirements for proliferation. The first is the 'conventional' CTL represented by our clone 17-11 and also isolated by others<sup>4,5,7-9</sup>. We present evidence here for the existence of a second type of CTL, exemplified by clone 17-4. In contrast to cells of the first category, this cell does not require independently derived sources of helper factor for proliferation, as shown by its ability to proliferate in response to stimulating cells bearing the sensitizing alloantigens. In this respect clone 17-4 is a helper cell-independent CTL clone, and represents, to our knowledge, the first proven clone with such characteristics to be reported.

We emphasize that clone 17-4 is the only CTL clone of the seven we have tested to date which exhibits responsiveness in MLC to allogeneic cells. Thus, the frequency of such cells in bulk MLC populations from which the clones are derived (or the frequency of detection) seems to be relatively low. However, the existence of this type of cell has recently been confirmed both independently (A. Glasebrook, personal communication) and in our own laboratory (D. Roopenian, unpublished observation).

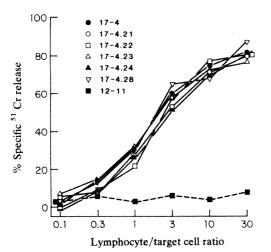

Fig. 1 Cytolytic activity of clone 17-4 and its subclones. Cells from clone 17-4 and five subclones (solid lines) and helper cell clone 12-11 (dashed line) were tested at the indicated effector cell/target cell ratios for cytolytic activity against  $2\times10^3$   $^{51}$ Cr-labelled P815 target cells in a 3.5-h assay<sup>14</sup>. Cells used for cytotoxicity testing were obtained 5 days after subculture.

Glasebrook and Fitch have reported that helper cell clones can utilize for proliferation growth factor(s) which they themselves produce12. Preliminary evidence suggests that cells of CTL clone 17-4, like cloned helper cells, secrete a soluble factor when stimulated with allogeneic cells which induces proliferation and cytolytic activity in resting, long-term (day 14) MLC populations. Whether the factor produced by clone 17-4 is the same as that (those) produced by the conventional type of non-cytolytic helper cell is not known, but such a factor could be involved with antigen in the induction of proliferation by the clone. We thus propose that clone 17-4 has both helper and CTL functions previously considered unique to different T-cell subsets. Such attributes would presumably constitute an effector T cell that depends only on antigen for expansion. Whether this type of cell represents a stage in the T-cell lineage before or after differentiation of cells exhibiting mutually exclusive functions remains unknown.

Present concepts of excitable membrane function are based primarily on knowledge of two classes of channels: those activated by neurotransmitters<sup>1</sup> and those activated by membrane potential2. Recent evidence suggests that these notions may have to be modified to include other channel types, such as special ion channels activated by membrane potential but regulated by ligands<sup>3-5</sup>. We report here studies on single channel currents recorded from heart muscle cells, in which we have found a channel, abundant in cardiac membrane, which does not seem to belong in any of the familiar categories. This channel shows little selectivity between cations, but excludes anions. It is activated by intracellular Ca ions but is not appreciably affected by membrane potential.

<sup>‡</sup> To whom correspondence should be addressed

Fig. 1 Recordings of single-ion currents at three channel from inside-out concentrations membrane patch of cultured (day 4) rat ventricular muscle cell at 26 °C. pipette (external side contained Na-saline membrane) with 6 µM Ca. The broken line above each trace marks zero current; inward current is shown as a downward deflection. The membrane patch was voltage-clamped to -70 mV, which is seen to require voltage-clamped to ~1.5 pA (patch resistance ~50  $G\Omega$ ) when all channels are closed. The unit current is ~2.7 pA (conductance 38 pS; in b and c two smaller inward current steps are clearly a, Bathing solution (cytoplasmic side of membrane) of Na-saline with 6 µM Ca (recording started soon after patch isolation). b, Bathing solution of K-saline with 1.5 µM Ca (flow started 11 s before

start of record). c, Bathing solution of 'Ca-free' saline + EGTA (10  $\mu$ M). Flow started a few seconds before start of record. After brief flickering, one channel remained open for 35 s before closing (the break in the record denotes a 22-s gap throughout which this channel alone remained open); then all channels remained closed while EGTA was still present in the solution. Re-addition of calcium (not shown) caused the channels to open again. Note the quiet baseline in a and b when all channels were closed and the increase in 'noise' when the channels were open.

In our experiments we used myocytes obtained from neonatal rat hearts and cultured by a method similar to that described elsewhere<sup>6</sup>. The cells were exposed to trypsin (0.025%) for 24 h before seeding on day 0 and used before day 7. We selected for our experiments single cells having spindle-like shapes and striations. Single-channel currents were recorded from isolated patches of membrane with either the cytoplasmic surface (inside-out patch) or the external surface (outside-out patch) facing the bathing solution<sup>7</sup>. The Na-saline solution contained (mM): NaCl, 137; KCl, 5.4; MgCl<sub>2</sub>, 1.05; HEPES buffer, 5.0; glucose, 10; pH 7.3. In the K-saline solution, NaCl was replaced by KCl. CaCl<sub>2</sub> was added, and the final Ca concentration determined by atomic absorption spectroscopy.

Channel currents of the type shown in Fig. 1 were seen in most isolated membrane patches. We have interpreted such records as arising from the superimposed currents of several independent channels that can only open and close, but we cannot exclude the possibility that individual channels have multiple equally spaced conductance levels. The rate of channel opening was clearly dependent on the Ca concentration on the cytoplasmic side of the membrane (see Fig. 1). Considerable channel activity was usually observed in the presence of 6 µM Ca (Fig. 1a). After reduction of the Ca concentration to 1 or 1.5 µM, the activity decreased (Fig. 1b) but was still substantial. In the presence of 'Ca-free' saline + EGTA (10 µM), all channels eventually closed (Fig. 1c). In several experiments it was possible to change from Ca-containing solution to EGTA-saline and back several times, and to observe repeatedly the disappearance and reappearance of the single-channel currents. The assessment of the Ca-concentration dependence of channel opening was complicated by the fact that even when the Ca concentration was kept constant, the channel opening rate was usually observed to decline over a period of several minutes. A subsequent increase in activity was often seen when the Ca concentration was raised (for example, to 20 or 50 µM). However, changes in Ca concentrations over a wide range did not affect single-channel conductance. In many experiments similar channel currents were observed when the patch clamp pipette was applied to the intact cell, without removal of the membrane patch; in these cases no obvious contracture of the cell was observed.

The opening and closing of the Ca-dependent channels did not show any strong dependence on membrane potential at a Ca concentration of  $20~\mu M$ . Single-channel currents occurred with

similar frequencies at membrane potentials from -140 mV to +70 mV. In other experiments, records were obtained while stepping the membrane potential either from -70 mV to +70 mV for 100 ms, or from -70 or -120 mV to -30 mV for 5 s. When a series of such records is averaged, if the number of open channels were voltage-dependent it would be expected that the mean current would show a relaxation towards a new equilibrium value following a step in membrane potential. Such relaxations were observed, but they were very small, indicating that the open-close equilibrium changes less than e-fold for 200 mV. We cannot exclude the possibility that stronger voltage dependence might be present in other conditions.

The opening and closing patterns of these channels are rather complex. In conditions of low activity when at most one channel

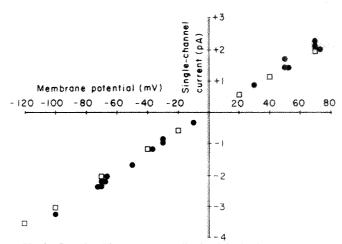

Fig. 2 Relationship between amplitude of single-channel current and membrane potential, with symmetrical and asymmetrical solutions at 25-26 °C. Values at positive potentials were obtained by short (100 or 200 ms) jumps from the holding potential (-70 mV) to a positive potential. All measurements were made at 10-mV intervals, but, when necessary for clarity, the symbols have been slightly offset horizontally. ♠, Na-saline with 20 μM Ca on both sides of the membrane; values from five different cells (insideout membrane patches) on day 6 of culture. □, K-saline with 1 μM Ca on cytoplasmic side of membrane, and Na-saline with 2 mM Ca on the external side of the membrane (outside-out membrane patch); cells were used on day 2 of culture.

was open, the mean open lifetime was about equal to its s.d. with values of ~100-300 ms. The shorter openings and poorly resolved spikes (see Fig. 1) represent channel lifetimes of this order. In most cases there were much longer channel openings of many seconds duration (Fig. 1). Often, for example, one channel appeared to be 'permanently' open and the resulting current formed a baseline on which the faster activity described above was superimposed. One channel seemed to remain open for ~35 s after addition of EGTA, before it eventually closed (see Fig. 1c). Even in patches where we had evidence for the presence of multiple channels, long periods occurred when one of the channels opened with a high probability and the other channels appeared not to function. This suggests that channels can also enter a long-lived closed state.

Conductance through the ion channel was approximately ohmic, as shown in Fig. 2 where the single-channel conductance was ~30 pS at 25 °C. Typically, single-channel conductances in over 50 patches ranged between 30 and 40 pS at 25-27 °C. Figure 2 shows that with identical saline on both sides of the membrane, the reversal potential for the channel current is close to the expected value of 0 mV. When all NaCl was replaced by KCl on the cytoplasmic surface (Fig. 2, □) the reversal potential was unchanged. Thus the ion channel must have similar permeabilities to Na and K ions. In another experiment we applied a salt gradient across the membrane by diluting the pipette saline to 1/5 with distilled water. Single-channel currents recorded in this condition reversed sign at -40 mV, as expected for cation selectivity. In addition, when chloride was replaced by the presumably less permanent anion, aspartate, the reversal potential did not change. These results indicate negligible anion permeability of the ion channels. The temperature dependence of the unit current (Fig. 3) has a  $Q_{10}$  of  $\sim 2.3$  (two experiments), which is unusually large; for example, a  $Q_{10}$  of 1.2-1.3 has been reported for ACh-activated channels<sup>8</sup>

In addition to the predominant channels described above, various other channel types were seen, including a number of small inward channel currents present at -70 mV (see Fig. 1b, c) and occasional Ca-dependent inward currents that were unusually large (50-60 pS). Voltage-dependent Na, Ca and K channels were also observed.

The ion channels described here resemble ACh-activated endplate channels in their conductance, and in their poor discrimination between Na and K ions, as well as in their low permeability to Cl ions<sup>10</sup> but their conductances are more temperature sensitive, have much longer open lifetimes, are less voltage dependent and are unaffected by carbachol. They resemble Ca-activated K channels 11,12 in that they are activated by Ca on the cytoplasmic side of the membrane, and in their

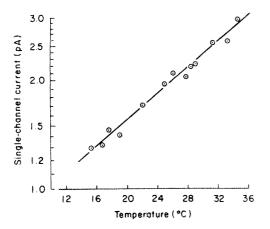

Fig. 3 Temperature dependence of the amplitude of the singlechannel current. The ordinate is a logarithmic scale. Cells were used on day 2. Inside-out membrane patch with K-saline + 20 µM Ca in the pipette and Na-saline + 20 µM Ca in the bathing solution; membrane potential -70 mV.

complex kinetics. However, they seem to require higher concentrations of Ca for activation, are not so voltage-dependent and lack the cation selectivity of Ca-activated K channels.

Several authors<sup>13-15</sup> have described oscillatory inward currents that occur in cardiac Purkinje fibres after depolarizing clamp steps during ouabain exposure or with high extracellular Ca concentration. This transient inward current has many features in common with the ion channels described here. It is activated by intracellular Ca ions and not by voltage directly and has a reversal potential around -5 mV indicating poor selectivity between Na and K ions<sup>14</sup>. Kass et al. <sup>14</sup> speculate that the underlying mechanism for the transient inward current could be non-selective 'leak' channels which, in normal conditions, would provide the background current required for pacemaking activity in cardiac cells. This hypothesis would be consistent with our results.

# Free Ca<sup>2+</sup> increases in exponential phases during mouse oocyte activation

K. S. Roy Cuthbertson\*, D. G. Whittingham\*‡ & Peter H. Cobbold†

MRC Mammalian Development Unit, University College London, Wolfson House, 4 Stephenson Way, London NW1 2HE, UK † Department of Zoology, The University of Liverpool, Brownlow Street, Liverpool L69 3BX, UK

A dramatic rise in cytoplasmic free Ca2+ concentration has been shown to occur during fertilization and artificial activation in the oocytes of both the medaka fish1 and sea urchin2. Indirect evidence has implicated Ca2+ in the parthenogenetic activation of mammalian oocytes. Mouse oocytes can be activated by the intracellular injection of Ca2+ but not Mg2+ (ref. 3), and hamster oocytes by exposure to the calcium ionophore, A23187 (ref. 4). We report here measurements of cytoplasmic free Ca2+ during the artificial activation and fertilization of single mouse oocytes injected with the Ca2+-sensitive photoprotein aequorin. Free Ca2+ rises exponentially from a resting level of below 0.1 μM to >5  $\mu M$  over a period of 10-30 min. A series of oscillatory Ca<sup>2+</sup> transients precedes this Ca<sup>2+</sup> rise during fertilization, but not during artificial activation.

The light from a single 'resting', unfertilized oocyte (70 µm diameter, 200 pl volume), injected with aequorin to  $\sim 5\%$  of its volume, ranged typically between 1 and 16 photoelectrons per s above a background of  $14 \, \text{s}^{-1}$  (Fig. 1A, B). The light signal was detected by holding the oocyte in a 75-µl-capacity reflecting cup positioned just below the photocathode of a low-noise photo-

<sup>‡</sup> Present address: MRC Laboratories, Carshalton, Surrey SM5 4EF, UK

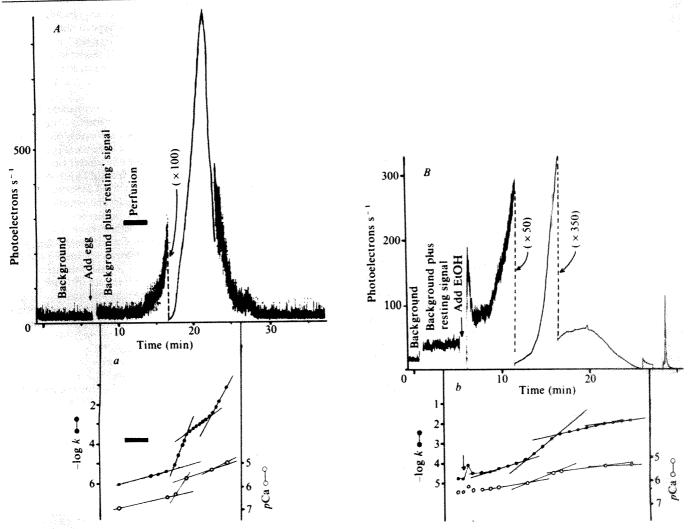

Fig. 1 A, a, Effect of an activating concentration of benzyl alcohol (0.5% v/v) on an aequorin-injected oocyte. A, Chart recording of the aequorin signal, expressed as photoelectrons s<sup>-1</sup> against time. The resting signal of 6 photoelectrons s<sup>-1</sup> remained constant until medium containing 0.5% benzyl alcohol was superfused (solid bar; the egg was exposed to benzyl alcohol up to the end of the experiment). Immediately the signal rose rapidly. The sensitivity of the recorder was reduced by a factor of 100 between 17 and 23 min. The signal returned to background level as the aequorin was consumed. In some experiments total consumption of aequorin was confirmed by adding SDS or distilled water to lyse the oocyte. a, The same data transformed to  $-\log k$  ( ) against time, where k is the fraction of acquorin consumed per s (that is, the ratio of the light signal in photoelectrons  $s^{-1}$  to the total number of photoelectrons yet to come from the active aequorin remaining in the oocyte). Note the piece-wise linearity of this plot, which implies that [Ca2+], increases in exponential phases. The plot is also shown in terms of pCa units (O). B, b, Effect of an activating concentration of ethanol (8.6% v/v) on an aequorin-injected oocyte. B, Chart recording of the aequorin signal in photoelectrons s<sup>-1</sup> against time. Recorder sensitivity was reduced 50-fold and 350-fold at 12 and 17 min. Ten microlitres of medium with the acquority signal in photoelectrons against time. Recorder sensitivity was reducted 50-load and 25-load at 25-load and 12-load and photoelectrons against time. Calibration measurements were made in vitro at 35 °C with EGTA Ca<sup>2+</sup> buffers containing (mM) KCl, 150; PIPES, 10; EGTA, 10; free Mg<sup>2+</sup>, 5 at pH 7.4. The stability constants of Ca–EGTA and Mg–EGTA, corrected for 37 °C and pH 7.4, were calculated at  $10^{7.44}$  and  $10^{2.46}$  M<sup>-1</sup> respectively 14. Our calibration curve of  $-\log k$  against pCa is linear (with slope 3.0) from  $-\log k = 5.5$  to 2.0. (Benzyl alcohol and ethanol have a direct effect on the emission of light by acquorin, as with other anaesthetics 15. Benzyl alcohol (0.5%) raised k by <0.1 log unit, but ethanol (8%) raised k by 0.8 log unit (P.H.C., unpublished results). This accounts for the initial jump in log k seen in the ethanol experiment (arrow). Quantum yield is not affected.) Occytes were collected from superovulated random-bred albino females (MF1; Olac, Bicester) and maintained at 37 °C in a Krebs-Ringer's bicarbonate-buffered medium (No. 16; ref. 16) gassed with 5% CO<sub>2</sub>, 95% air. Cumulus cells were removed with hyaluronidase in medium 16. Oocytes for the fertilization experiments were treated, after injection, with 0.03% α-chymotrypsin (type II; Sigma) to remove the zona pellucida. Oocytes were injected at room temperature in medium M2 (ref. 3), which is medium 16 modified by partly replacing the bicarbonate buffer with HEPES buffer. The aequorin was dialysed against an injection buffer containing 30, 80 or 150 mM KCl, 10 μM 3-(N-morpholino)propanesulphonic acid (MOPS) and 25 μM EDTA, pH 9.0. Micropipettes with a tip diameter of -2 m were pressure-filled (at 7 bar) through the tip5 with the acquorin solution, which was injected by pulses of gas pressure (up to 2 bar) into an oocyte held on a siliconized heat-polished pipette. The oocyte was contained in a minimal bubble of medium at the end of the holding pipette, surrounded by silicone oil (M100; Bayer, Leverkusen). The aequorin was thus protected from the Ca<sup>2+</sup> in the medium before penetration of the oocyte. All Ca<sup>2+</sup> measurements described were done in medium 16 at 35 °C, except for the two experiments shown here, in which medium M2 was used. Oocytes were between 15 and 22 h post-HCG (human chorionic gonadotropin) at the time of the experiments.

multiplier. Detection limits proved to be better than predicted. Assuming homogeneous Ca<sup>2+</sup> distribution, and assuming that the conditions in vivo can be sufficiently matched in vitro, the rate of aequorin consumption, k, can be calibrated<sup>6,7</sup> for a given  $Mg^{2+}$  concentration, to give the free intracellular  $Ca^{2+}$  concentration,  $[Ca^{2+}]_i$ . The mean value of k measured in 21 'resting' oocytes at 35 °C corresponds to values for  $[Ca^{2+}]_i$  of  $5\pm1\times10^{-8}$  M if  $[Mg^{2+}]_i$  is 5 mM, and  $1.3\pm0.1\times10^{-7}$  M if  $[Mg^{2+}]_i$  is 10 mM. For 10 of the oocytes,  $\log k$  was less than the value for  $Ca^{2+}$ -independent light emission with 5 mM  $Mg^{2+}$  ( $\log k = -6.25$ ), which suggests that, for these oocytes at least,  $[Mg^{2+}]_i$  was greater than 5 mM. If  $[Mg^{2+}]_i$  can vary significantly between

oocytes, then the resting  $[Ca^{2+}]_i$  could be substantially lower than  $1 \times 10^{-7}$  M.

Brief treatment (5–10 min) of mouse oocytes with benzyl alcohol (a local anaesthetic) or ethanol induces activation; that is, meiosis II proceeds and pronuclei form, and over 70% of the activated oocytes can develop into blastocysts when cultured for a further 4 days<sup>8</sup>. On exposure of aequorin-injected oocytes to medium containing an activating concentration of benzyl alcohol (0.3–0.5%) or ethanol (5.0–8.6%),  $[Ca^{2+}]_i$  rose to  $5 \times 10^{-6}$  M (Fig. 1). A slightly lower concentration of benzyl alcohol (0.2%) did not induce this dramatic change in  $[Ca^{2+}]_i$ , although a small increase in signal was sometimes detected. Similarly, large

increases in  $[Ca^{2+}]_i$  were seen, after delays of up to 1 h, in oocytes held in Ca-free medium (2/3 oocytes), Ca-free medium with 1 mM Sr<sup>2+</sup> added (2/3 oocytes, Fig. 3C) and normal Ca-containing medium without any experimental intervention (11/54 oocytes). The observation of the  $Ca^{2+}$  change in oocytes in Ca-free medium explains the apparent paradox that both the injection of  $Ca^{2+}$  (ref. 3) and exposure to Ca-free medium<sup>9,10</sup> activate oocytes.  $Ca^{2+}$  rose to  $5\times 10^{-6}$  M in oocytes in Ca-free medium with the same time course as spontaneously activating oocytes in medium containing 1.71 mM Ca, suggesting that the increase in  $[Ca^{2+}]_i$  is due to the release of  $Ca^{2+}$  from internal stores.  $Sr^{2+}$  enhances activation in Ca-free medium<sup>10</sup>, but does not alter the form of the  $Ca^{2+}$  release.

To compare the [Ca2+] responses during artificial activation with the response during fertilization, single zona-free oocytes containing aequorin were placed with sperm under the photomultiplier. In three oocytes, a series of 8 to 12 Ca2+ transients was observed after delays of between 5 and 90 min (Fig. 2). These transients occurred over a period of 45 min in two of the oocytes and 90 min in the third, and preceded a large [Ca<sup>2+</sup>], rise similar to that seen during artificial activation (Fig. 3A, B). The first two or three transients had 4-6 oscillations of large amplitude. The rapid rise and fall of the transients and the oscillations within each transient are in contrast to the slow rise during artificial activation, and the base level between transients starts to rise towards the end of the series in the first phase of the 'activating' rise in [Ca<sup>2+</sup>]<sub>i</sub> (data not shown). This suggests that the signal during the transients does not arise from the entire oocyte, but rather from a localized region, which may be at the site of sperm-egg fusion or near to the plasma membrane of the oocyte. In the medaka fish oocyte (diameter ~1 mm) the [Ca<sup>2+</sup>], increase starts at the site of sperm-egg fusion and then spreads around the cell1. Each series of transients forms a coherent pattern. Thus we believe that a single sperm can initiate a series of transients; these were never seen when oocytes were

activated in the absence of sperm (35 oocytes). In addition, a single fertilizing sperm induces recurring hyperpolarizations in hamster oocytes<sup>11</sup>, which could be caused by cyclic increases in  $[Ca^{2+}]_i$  corresponding to the  $Ca^{2+}$  transients reported here. It is therefore likely that the series of  $Ca^{2+}$  transients were induced by fertilizing sperm, although it was not possible to confirm that sperm had penetrated the oocytes.

The rise in [Ca<sup>2+</sup>], during activation is piece-wise exponential; that is,  $pCa \left(-\log \left[Ca^{2+}\right]_{i}\right)$  increases linearly with time within successive phases (Figs 1a, b, and 3). In some cases four phases were discernible, giving the appearance of a zigzag (Figs 1, 3C). In one case (see Fig. 3B) there was just one phase. Linearity is seen, to within observational accuracy, from pCa = 6.4 to 5.4, that is, during a 10-fold increase in  $[Ca^{2+}]_i$ . Linearity of  $\log k$ within phases was consistently observed. The simplest interpretation is that [Ca<sup>2+</sup>], rose uniformly throughout the whole cytoplasm, in which case the rise within each phase was exponential, and therefore the rate of Ca2+ increase was proportional to [Ca<sup>2+</sup>]<sub>i</sub>. If [Ca<sup>2+</sup>]<sub>i</sub> is not uniform, the interpretation of k becomes complex, particularly as k is a nonlinear function of  $[Ca^{2+}]$ , and a model to account for linearity in  $\log k$  would have to include the diffusion of aequorin as well as Ca2+. While the light signal reached a peak and then dropped rapidly  $\log k$ was often still rising linearly (for example, as in Fig. 1a). The fall in light signal was due to the consumption of aequorin. In this circumstance the dependence of the rate of Ca2+ increase on  $[Ca^{2+}]_i$  necessary to account for the linearity in  $\log k$  would become highly contrived if it were assumed that [Ca<sup>2+</sup>], was significantly non-uniform. Step changes in the slope of the graph of pCa could be generated by step changes in the Ca2+ release parameter (the ratio of the net rate of Ca2+ release to [Ca2+], denoted by  $R_{Ca}$ ). A biochemical system such as that proposed for biochemical oscillators<sup>12</sup> might determine the value of  $R_{Ca}$ . Alternation between stable states of this system might cause step changes in  $R_{Ca}$ . A step increase in  $R_{Ca}$  which raises the rate of

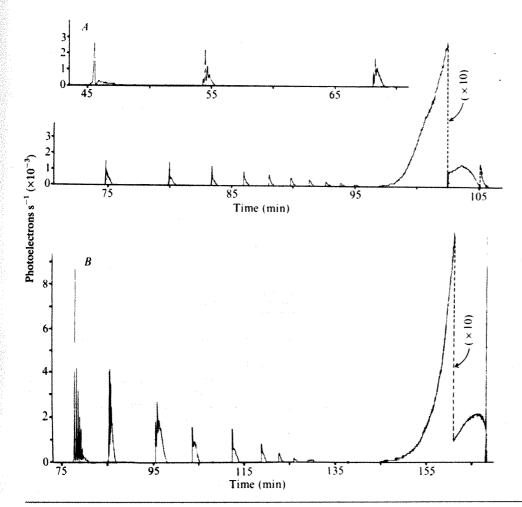

Fig. 2 Aequorin signals (photoelectrons s against time) from single zona-free oocytes in the presence of sperm (~10<sup>6</sup> per ml), recorded with digital photon-counting equipment. A, Sperm were added at 0 min. The first Ca<sup>2+</sup> transient is seen at 45 min, and a series of transients then follows before the dramatic Ca<sup>2+</sup> rise beginning at rise beginning at 97 min. Recorder sensitivity was reduced 10-fold at 102 min and returned to normal at 105 min. The trace ends at 106 min, the aequorin having been consumed completely. B, A similar experiment recorded at a slower chart speed. The trace has been re-drawn from 85 to 135 min to give a constant time scale. Note the oscillations in the first two transients. (The constant lower limit of the oscillations in the first transient is an artefact of the digital recording.) Throughout the series the transients decline in peak height and duration, and occur more frequently later in the series. The last few transients in each series are superimposed on a slow exponentially rising phase in the base level of [Ca<sup>2+</sup>]<sub>i</sub>, recorded at high gain from the analog output of the photon counter. This is not seen on the digital recording shown.

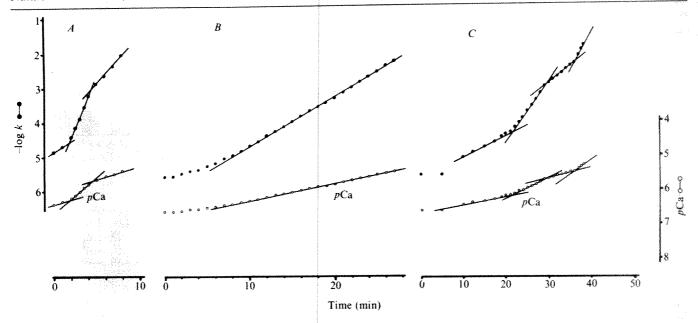

Fig. 3 A, B, fertilization data from Fig. 2 transformed into plots of −log k (●) and pCa (○) against time (see Fig. 1 legend for details), for the period of the large, 'activating' rise in [Ca<sup>2+</sup>]<sub>i</sub>. C, plots of -log k (•) and pCa (O) against time for the [Ca<sup>2+</sup>]<sub>i</sub>. l rise in an oocyte in Ca-free medium 16 containing 1 mM SrCl<sub>2</sub>. At the start of the plots shown, the oocyte had been in this medium for 45 min, with no change in the signal. Straight lines have been drawn through the points to show the piece-wise linearity of the plots.

Ca2+ release above that of Ca2+ sequestration would initiate an exponential rise in [Ca2+]i. This might be the first event in the process of activation, rather than a rise in [Ca<sup>2+</sup>], above a threshold. The probability of this event occurring may be increased by changes in [Ca<sup>2+</sup>], near the plasma membrane. This local Ca<sup>2+</sup> concentration may fall in Ca-free medium (because of reduced Ca<sup>2+</sup> influx) and rise with benzyl alcohol treatment and the Ca2+ transients seen in the fertilization experiments. Thus the initial effects of activating stimuli are various, but all serve to destabilize the system controlling  $R_{Ca}$ . Therefore the rises in [Ca<sup>2+</sup>], that result are similar.

Here we have given direct evidence that a large increase in [Ca<sup>2+</sup>] is an early event during activation of mouse oocytes. The time course of the [Ca<sup>2+</sup>], increase is an order of magnitude slower than the similar [Ca<sup>2+</sup>], increase seen in medaka<sup>1</sup> and sea urchin<sup>2</sup> oocytes. The data suggest that this [Ca<sup>2+</sup>], change depends on positive feedback which is itself controlled by an underlying system. An understanding of this system will be needed to explain fully the phenomenon of activation by various stimuli<sup>13</sup>. The technique used here to measure [Ca<sup>2+</sup>], in single mouse oocytes might provide a suitable model system for other cells where changes in [Ca2+], are important.

We thank Dr O. Shimomura for gifts of aequorin and Dr H. Block for advice on EGTA buffers. We acknowledge the support of a MRC studentship (to K.S.R.C.) and a SRC grant (to P.H.C.).

#### **B-Endorphin and dynorphin control** serum luteinizing hormone level in immature female rats

Rüdiger Schulz, Annemarie Wilhelm, Karl Martin Pirke\*, Christian Gramsch & Albert Herz

Department of Neuropharmacology, Max-Planck-Institut für Psychiatrie, Kraepelinstrasse 2, D-8000 München 40, FRG \* Department of Clinical Chemistry, Max-Planck-Institut für Psychiatrie, Kraepelinstrasse 10, D-8000 München 40, FRG

The suppressive effect of opioid administration on secretion of luteinizing hormone (LH) probably originates primarily in the hypothalamus<sup>1-5</sup>. Furthermore, the endogenous ligands of the opiate receptors (endorphins) seem to exert a tonic inhibition on the hypothalamic-pituitary-LH axis, as blockade of opiate receptors by the narcotic antagonist naloxone causes a pronounced increase in the release of LH3.4. However, it is unknown which of the particular endorphins present in the hypothalamus is responsible for this tonic inhibition. In addressing this issue we hypothesized that a similar effect to that obtained by blocking receptors with naloxone would be achieved by reducing the concentration of a specific endorphin at the receptors using antibodies against specific opioid peptides. We report here that both anti- $\beta$ -endorphin antibodies and anti-dynorphin<sub>1-13</sub> antibodies, when injected into the arcuate nucleus of the mediobasal hypothalamus (MBH) of immature female rats, caused an increase in serum LH. Anti-methionineenkephalin (Met-enkephalin) antibodies did not affect LH levels. We conclude that  $\beta$ -endorphin and dynorphin rather than Met-enkephalin have a role in regulation of LH secretion in immature female rats. These may represent the first data ascribing a specific physiological function to a particular endorphin.

Morphine, the enkephalins and  $\beta$ -endorphin exert their actions in the MBH by modulating the LH secreting activity of the pituitary<sup>3,5</sup>. The tonic inhibition effected by the endorphins

has been most convincingly documented in immature female rats: a dramatic (10-fold) increase in serum LH levels is seen within a few minutes of naloxone administration<sup>6,7</sup>. Assuming a competitive antagonism between naloxone and endorphins, the question remains as to which of the endogenous ligands of the opiate receptors actually controls the hypothalamus-pituitary-LH axis. This is of particular interest in view of the existence of a number of endorphins in the MBH<sup>8-11</sup>, which most probably correspond to multiple opiate receptors. In this respect, naloxone cannot provide more precise information as it acts almost equally well on each of the different opiate receptors. A promising system in which to investigate this issue seems, therefore, to be the extremely naloxone-sensitive hypothalamus-pituitary-LH axis of immature female rats. Microinjections into the MBH of specific anti-endorphin antibodies should neutralize the endorphins to give an elevation of serum LH, thus revealing the type of endorphin responsible for the tonic inhibition. This technique has been used successfully in the elucidation of different physiological mechanisms by administering antibodies either centrally 12-14 or peripherally 15

Anti-β-endorphin (titre 1:50,000; 50% binding of 15 fmol 125I tracer), anti-dynorphin<sub>1-13</sub> (1:20,000) and anti-Met-enkephalin (1:1,000) antisera were obtained and partially characterized as described elsewhere 10,19,20. As the titres of antidynorphin and anti-Met-enkephalin antisera were relatively low, we isolated the respective immunoglobulins by means of Protein A-Sepharose<sup>21</sup> and concentrated them to a final titre of 1:80,000. Anti- $\beta$ -endorphin antiserum (1:50,000) at a concentration of 1 μl was able to bind ~6 pmol <sup>125</sup>I-β-endorphin. The corresponding values were 8 pmol for the concentrated anti-dynorphin antibody (1:80,000) and 10 pmol for anti-Met-enkephalin antibody (1:80,000). The affinities of the antisera for their respective antigens were anti- $\beta$ -endorphin,  $7.0 \times 10^{11} \, \mathrm{l} \, \mathrm{mol}^{-1}$ ; anti-dynorphin  $1.1 \times 10^{10} \, \mathrm{l} \, \mathrm{mol}^{-1}$ ; and anti-Met-enkephalin,  $2.1 \times 10^{10} \, \mathrm{l} \, \mathrm{mol}^{-1}$ . CN-activated Sepharose 4B coupled to  $\beta$ -endorphin, dynorphin<sub>1-13</sub> and Met-enkephalin, respectively, was used to remove selectively the antibodies from the anti- $\beta$ -endorphin antiserum or the solutions containing the concentrated anti-dynorphin or anti-Met-enkephalin antibodies<sup>19</sup>. The remaining solutions completely lost their binding capacity and served as controls.

The powerful effect of naloxone (2.5 mg per kg s.c. (subcutaneous)) on serum LH levels in naive immature female rats<sup>6.7</sup> is confirmed here. LH levels increased to  $420\pm21$  ng ml<sup>-1</sup> (n=16) in 12-day rats (saline controls:  $43\pm19$ , n=24) 30 min after naloxone treatment and to  $381\pm16$  ng ml<sup>-1</sup> (n=11) in 14-day rats (controls:  $47\pm15$ , n=16). In 12-day female rats anaesthetized with hexobarbital (100 mg per kg s.c.) the antagonist increased the LH level to  $370\pm25$  ng ml<sup>-1</sup> (n=39) (saline controls:  $62\pm21$ , n=27).

In further experiments, unilateral microinjections (1 µl) of specific anti-endorphin antibodies were performed only on 12day female rats anaesthetized with hexobarbital (100 mg per kg s.c.). After 40 min the rats were decapitated, the blood collected and the brains removed. The serum LH concentrations determined were compared with the site of injection in the MBH, identified by histological examination. Figure 1 shows LH levels in rats after microinjection of different antibodies into distinct areas of the MBH. Figure 1a shows results for anti- $\beta$ -endorphin antiserum (titre 1:50,000); of nine areas injected, only injections into the arcuate nucleus were followed by an increase in LH (fourfold). A similar pattern was observed for antidynorphin<sub>1-13</sub> antibody (titre 1:80,000; Fig. 1b). Although the LH response after injection into the arcuate nucleus was less (twofold) than that observed with anti- $\beta$ -endorphin antiserum, the effect was highly significant (P < 0.01). Furthermore, LH levels doubled (P < 0.01) on injection of anti-dynorphin antibody into the nucleus dorsomedialis (pars ventralis); the control values for this area were the lowest of all obtained. Thus, although there was a statistically significant increase in LH in this case, the functional relevance of these data is questionable. In general, the control values were greater than those shown in

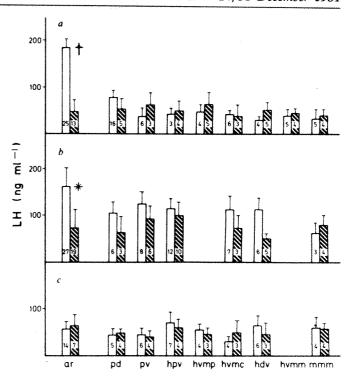

Fig. 1 Serum LH levels in 12-day-old female rats. The anaesthetized animals (hexobarbital, 100 mg per kg s.c.) were microinjected with: a, 1 µl anti- $\beta$ -endorphin antiserum (titre 1:50,000); b, anti-dynorphin<sub>1-13</sub> immunoglobulin-containing solution (1:80,000); or c, or anti-Met-enkephalin immunoglobulin-containing solution into different areas of the mediobasal hypothalamus (open columns). The hatched columns represent data from rats injected with 'carrier' solutions lacking the specific endorphin immunoglobulins. The animals were decapitated 40 min after the stereotaxically guided administration of the antibodies (5 µl Hamilton syringe, flat tip of the needle). Pilot studies on rats killed 20 min after antibody injection did not reveal changes in serum LH levels. The antibodies were injected within 3 min and the needle left in place for a further 3 min; experiments were done between 9.00 and 13.00 h. The trunk blood of the decapitated animals was collected, and the serum collected after 30 min at room temperature by centrifugation. The samples were stored at -20 °C and assayed in duplicate for LH as described in detail elsewhere26, using reagents provided by the Pituitary Agency of the National Institutes of Health. Variability within assays was 10% at an average level of 41 ng LHRP-1 (luteinizing hormone rat pituitary standard) per ml. The cannula position was verified by histological examination according to König and Klippel<sup>27</sup> Apparently, driving the needle through the median eminence caused extremely high serum LH levels (>800 ng ml<sup>-1</sup>). Anti-β-endorphin antibodies labelled with <sup>125</sup>I by the Chloramine-T method were used to study their diffusion within the hypothalamus. Punching the tissue around the site of injection revealed that the antibodies penetrated less than 1.8 mm from the site of injection within 40 min. The columns represent mean serum LH levels of different animals (number of animals shown within columns). Vertical bars indicate s.e. Significance of differences was calculated according to the two-tailed Student's t-test (\*P<0.01; †P<0.001). Data are given only for more than two injections into a certain area. The areas injected are indicated on the abscissa, abbreviated according to König and Klippel<sup>27</sup>: ar, nucleus arcuatus; pd, nucleus premamillaris dorsalis; pv, nucleus premamillaris ventralis; hpv, nucleus periventricularis (hypothalami); hvmp, nucleus ventromedialis (hypothalami), pars posterior; hvmc, nucleus ventromedialis (hypothalami), pars centralis; hdv, nucleus dorsomedialis (hypothalami), pars ventralis; hvmm, nucleus ventromedialis (hypothalami), pars medialis; mmm, nucleus mamillaris medialis, pars medialis.

Fig. 1a, c. We assume that this reflects the presence of impurities due to the processing of the anti-dynorphin antiserum. In contrast to the data obtained with anti- $\beta$ -endorphin and anti-dynorphin antisera, none of the areas injected with anti-Metenkephalin antibody (titre 1:80,000) responded with an increase in serum LH concentration (Fig. 1c). These results were obtained for high concentrations of antibodies (anti- $\beta$ -endorphin antiserum titre 1:50,000; anti-dynorphin<sub>1-13</sub> and anti-Met-enkephalin, each 1:80,000). Injections of  $1 \mu l$  anti- $\beta$ -endorphin antiserum diluted 10-fold (1:5,000) did not raise LH concentrations. Similarly, anti-dynorphin<sub>1-13</sub> antiserum (titre

1:20,000; not enriched) or anti-Met-enkephalin antiserum (1:1,000) failed to increase LH levels.

The observations reported here support the concept of a tonic inhibitory effect of endorphins on the hypothalamus-pituitary-LH axis. Two findings are of particular importance. First, LH levels are affected not only by anti- $\beta$ -endorphin antibodies but also, although to a lesser degree, by anti-dynorphin<sub>1-13</sub> antibodies. Second, the arcuate nucleus was the only sensitive region in a number of areas of the MBH tested. The fact that dopaminecontaining neurones and  $\beta$ -endorphin-containing neurones are closely associated in the arcuate nucleus<sup>22</sup>, together with our present findings, supports the notion of an interaction between endorphinergic and dopaminergic mechanisms in the modulation of the release of LH-releasing hormone from the median eminence<sup>1,2,5</sup>. The experiments implicating dynorphin in the control of serum LH via the arcuate nucleus are less compelling than the data suggesting a role for  $\beta$ -endorphin. However, in support of a regulatory role of dynorphin<sub>1-13</sub> are its high immunoreactive content in this area (1-5 pmol per mg protein)9-11 and its extremely high potency2

The finding that Met-enkephalin probably does not regulate serum LH in immature female rats is of interest in view of the conflicting data obtained from adult rats. Goldberg et al.2 reported that Met-enkephalin had no effect on serum LH concentrations, whereas others 1.2 have observed an inhibitory action of Met-enkephalin on the release of LH-releasing hormone in mediobasal hypothalamic slices. However, the Metenkephalin concentrations used in these studies were far greater than the K<sub>d</sub> value for Met-enkephalin (0.66 nM)<sup>25</sup>, therefore other receptors could also be activated by this opioid peptide. The general question remains whether mechanisms responsible for modulation of LH release in adult rats are similar or identical to those which operate in 12-day-old female

We thank Drs K. J. Chang, A. Goldstein and R. J. Miller for providing fractions of the antisera used; Dr S. Raiti for the LH-assay standard; Ms B. Kerker for technical assistance; and Dr M. J. Millan for revision of the text.

#### Effects of nifedipine on electrical and mechanical responses of rat and guinea pig vas deferens

A. G. H. Blakeley\*, D. A. Brown†, T. C. Cunnane\*, A. M. French‡, J. C. McGrath† & N. C. Scott‡

The mechanical response of the vas deferens to single pulses or short trains of stimuli can be resolved into two distinct phases, an initial twitch response (I) attributed to the release of an unknown transmitter and a slower better maintained secondary contraction (II)1,2, attributed to noradrenaline release. Recently, it has been shown that the calcium antagonist nifedipine3 eliminates the initial twitch response leaving the secondary component intact<sup>4,5</sup> and we have now examined the electrical responses underlying these mechanical events. We show here that nifedipine abolishes the smooth muscle action potential and the initial twitch response (I) without reducing the excitatory junction potential (e.j.p.), suggesting a fundamentally different basis of the two responses and illustrating the pharmacological value of nifedipine.

In rat and guinea pig, the contractile response of the vas deferens to a single field stimulus to the sympathetic innervation consisted of several components. In the rat this response could be separated into two components; a rapid, early (200-300 ms) response  $(I_s)$  and a slower (600-700 ms) response  $(II_s)$ . The  $\alpha_1$ -adrenoreceptor antagonists, prazosin  $(10^{-7} \,\mathrm{M})$  or corynanthine  $(3 \times 10^{-6} \text{ M})$ , blocked  $II_s$  but left  $I_s$  intact. In contrast, nifedipine  $(10^{-5} \text{ M})$  together with  $\alpha_1$ -adrenoreceptor antagonists virtually eliminated the whole response (Fig. 1).

In the guinea pig, where separation of the mechanical response to single stimuli by time course into two distinct components is less clear than in the rat2.6, corynanthine had little effect but nifedipine reduced the response by 40-70% and, by producing a relatively greater inhibition of the early part of the contraction, altered the time course. Thus, in each species the contractile response to a single stimulus contained a nifedipinesensitive but  $\alpha_1$ -antagonist-resistant component  $(I_s)$  and an  $\alpha$ -noradrenergic component  $(H_s)$ .

In each species, a train of 25 pulses at 6 Hz produced a biphasic concentration, a rapid, early (1-2s) component  $(I_t)$ followed by a second component  $(II_t)$ , which lasted until stimulation ceased, I, and II, being relatively dominant in the prostatic and epididymal portions, respectively<sup>6,7</sup>. In each species, corynanthine (3×10<sup>-6</sup> M) produced inhibition which was greater in II, but which, again, did not exceed 50%. In contrast, nifedipine, although reducing each component, produced a particularly marked reduction of up to 90% in  $I_{\rm b}$ . The effects of nifedipine and corynanthine were additive but did not result in complete abolition of the response. Thus, in each species, each phase of the response contained a nifedipine-sensitive component which was a dominant factor in  $I_t$ . In contrast the component attributed to  $\alpha$ -noradrenergic activation contributed mainly to  $H_t$ , particularly in the guinea pig where the noradrenergic component to single pulse is less obvious. The nifedipine-sensitive component corresponded in drug sensitivity, time course and species specificity to the nerve-induced 'non-noradrenergic' contraction 1,2,6,7

In separate experiments on the guinea pig vas deferens, e.j.ps and action potentials were recorded using intracellular microelectrodes (20-40 M $\Omega$  filled with 3M KCl) following pre- and

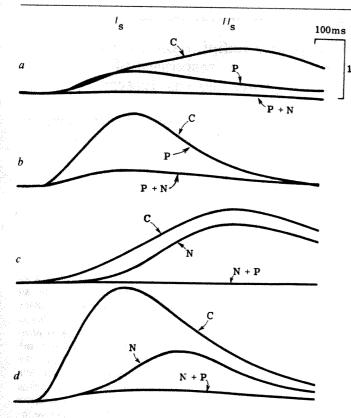

Fig. 1 Effects of drugs on the time courses of the isometric contractions of isolated portions of rat vas deferens to single supramaximal field stimuli (0.5 ms). The trace was triggered by the stimulus. a, The epididymal and b, the prostatic portions of a vas deferens. Control (C) was followed by responses in the presence of prazosin  $(10^{-7} \text{ M})$  (P) and then with the further addition of nifedipine  $(10^{-5} \text{ M})$  (P+N). In this particular experiment, prazosin had no effect at all in b so C and P coincide. c, d, The contralateral vas—as for a and b except that nifedipine (N) was administered first and was followed by the addition of prazosin (N+P).  $I_s$  and  $I_s$  indicate the times of the peaks of the two phases of contraction.

postganglionic hypogastric nerve stimulation with trains of stimuli at 5-10 Hz, pulse width 0.2 ms and supramaximal voltage<sup>8</sup>.

In all preparations, trains of stimuli at 5 Hz evoked e.j.ps which by facilitation and summation reached threshold for the initiation of a muscle action potential and the vas deferens contracted violently, normally dislodging the microelectrode. The muscle action potential had an overshoot of >15 mV in all control cells impaled. At 10-15 min after nifedipine (10<sup>-5</sup> M to  $3 \times 10^{-5}$  M), the e.j.p. was not reduced, and if anything was enhanced. Trains of stimuli now produced a depolarization which greatly exceeded the control threshold, but it was not possible to induce muscle action potentials (Fig. 2) even with trains of stimuli at 10 Hz. Nifedipine reduced the rate of rise and fall of the spike before complete block occurred (Fig. 3). During long trains of stimuli at 5 and 10 Hz, the microelectrode was dislodged from the cell presumably due to contraction of the vas deferens, even though no action potentials were recorded. After wash-out (15 min) the muscle action potential began to return (Fig. 2) although the rate of rise was still greatly reduced compared with the control.

The  $\alpha$ -adrenoreceptor antagonist prazosin ( $10^{-6}$  M) did not reduce the muscle action potential but increased e.j.p. amplitude. Prazosin did not prevent the effects of nifedipine ( $3 \times 10^{-5}$  M), suggesting that nifedipine is not acting via an  $\alpha$ -adrenoreceptor.

Previously, it has not been possible to block selectively the initial twitch and leave the secondary response (II) intact. We have now shown that nifedipine blocks the initial twitch (I) and prevents the initiation of the smooth muscle action potential.

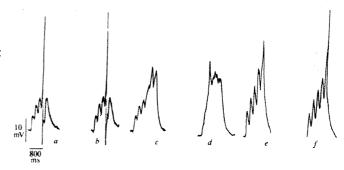

Fig. 2 Effects of nifedipine  $(10^{-5} \text{ M})$  on excitatory junction potentials and action potentials evoked in the guinea pig vas deferens by hypogastric nerve stimulation (pulse width 0.2 ms, supramaximal voltage). Stimulus artefacts have been removed from the trace. a, b, Controls, resting membrane potential (RP) – 57 mV and –56 mV respectively. Response evoked by trains of five pulses at 5 Hz. c, 15 min after nifedipine; RP = -62 mV, six pulses at 5 Hz. d, Same cell as d, 10 pulses at 10 Hz. d, Wash 10 min; RP = -63 mV, five pulses at 5 Hz. d, Same cell as d, 15 min wash; five pulses at 5 Hz. Records d/d, d/d and d/d are taken from three neighbouring cells in the same preparation.

Nifedipine is known to be a calcium antagonist without local anaesthetic activity and it is also known that calcium is the ion carrying most of the inward current during the rising phase of the action potential  $^{10-12}$ . The initial twitch response (I) therefore corresponds to the contraction associated with the smooth muscle action potential. Since the e.j.p. initiates the smooth muscle action potential and associated contraction, and is resistant to concentrations of  $\alpha$ -adrenoreceptor antagonists which block the noradrenergic contraction, it is probable that the  $\alpha$ -adrenoreceptor mediated contractile response of the vas deferens does not require an action potential.

These results show there to be a fundamental difference between the two types of response to nerve stimulation in the vas deferens. If noradrenaline is the sole transmitter then it

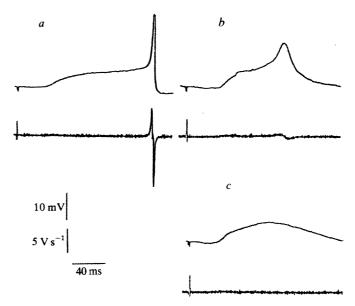

Fig. 3 The effects of nifedipine  $(10^{-5} \text{ M})$  on action potentials in the guinea pig vas deferens. Action potentials were evoked by stimulation of the hypogastric nerve with trains of five stimuli at 5 Hz. The records show the membrane response initiated by the fourth stimulus in a train. The upper record is the d.c. response calibration bar 10 mV; lower record, the differential of the d.c. signal, calibration bar  $5 \text{ Vs}^{-1}$ . a, Control, resting membrane potential (RP) -62 mV; b, 10 min after nifedipine, RP = -64 mV. Records a, b and c are taken from three neighbouring cells in the same preparation.

produces its contractile effects through two processes; the first involves e.j.ps which summate to initiate propagated action potentials and does not involve  $\alpha$ -adrenoreceptors; the second does not involve e.j.ps or propagated action potentials but is mediated by  $\alpha_1$ -adrenoreceptors. The only experimental obstacle which remains to acceptance of noradrenaline as sole transmitter is the survival of the first process after reserpine or chemical sympathectomy<sup>13</sup>. The results provide further proof that the different types of response in the two ends of the vas result from differences in the dominant transmission process.

These results in vas deferens show some similarities with recent data derived from arteriolar smooth muscle 14,15. First, in

each case the e.j.p. was found to be resistant to  $\alpha_1$ -adrenoreceptor antagonists. Second, in the responses which are mediated by  $\alpha_1$ -adrenoreceptors in these tissues, there is a similarity between the contractile response of the arterioles to iontophoretically applied noradrenaline, which occurred without any detectable change in membrane potential, and the 'adrenergic' response to nerve stimulation in the vas, which occurred independently of the action potential. This suggests that in smooth muscle there is a type of  $\alpha_1$ -adrenoreceptor which may directly activate the contractile process without utilising the nifedipine-sensitive influx of calcium associated with the rising phase of the action potential.

Electrophysiological and pharmacological studies 1-6 indicate that the specific responses of most visual cortical neurones depend on intracortical y-aminobutyric acid (GABA)-mediated inhibitory processes. GABAergic interneurones have been visualized in all layers of the mammalian cerebral cortex by immunocytochemical methods 7.8 and by high-affinity uptake of exogenous 3H-GABA9-11. It is recognized that GABA is synthesized and specifically accumulated by aspinous and sparsely spinous stellate cells, but there is no evidence available to indicate whether the laminar distribution of these cells and their axonal projections are related to the known role of GABAergic inhibitory processes in the generation of responses in visual cortical cells. It would therefore be of value to delineate the intracortical projection of the axons of different types of GABA-releasing neurones in regions of cortex where the receptive field properties of the neurones, and their modification by GABA antagonists, are well known. The selective highaffinity uptake of labelled GABA has been useful in delineating GABAergic systems12: recently, it has been shown that exogenous 3H-GABA is specifically taken up and transported retrogradely by axons of neurones thought to be GABAergic 13,14. Using microinjections of 3H-GABA into different layers of the monkey visual cortex, we have examined the pattern of labelled neurones. We report here a bimodal distribution of GABA-accumulating neurones after injection into layers V and VI, with one group of neurones around the injection site and the other directly above, in layers II and III. We provide evidence that the latter neurones are non-pyramidal cells, probably labelled by retrograde axonal transport from the deep lavers.

Two adolescent male macaque monkeys were used. One had taken part in behavioural tests of memory and had received surgical section of the fornix 6 months before the present study. The other had a high antibody titre to Herpes simiae and could therefore not be used in long-term experiments. There was no reason to suppose that the visual cortex of either monkey was abnormal. The animal was sedated with an intramuscular injection of ketamine hydrochloride (10 mg per kg; Ketalar, Parke-Davis) and then deeply anaesthetized with an intravenous injection of sodium pentobarbitone (Sagatal, May and Baker). After exposing the lateral surface of one occipital lobe, the cortex was injected with <sup>3</sup>H-GABA (0.33 mM, 60 Ci mmol<sup>-1</sup>; Radiochemical Centre) dissolved in Krebs bicarbonate<sup>15</sup>. All the injections were delivered using glass micropipettes (30-50 µm tip diameter) penetrating at a very oblique angle to the surface of the cortex. The pipette was advanced 7-9 mm from the pia and 0.1 µl (2 µCi) 3H-GABA injected by pressure16 at each of four to six sites at 1-2 mm intervals along the injection track as the capillary was gradually withdrawn. In the first monkey the GABA injection track (no. 1) in area 17 passed obliquely through layers V and VI and ended in the white matter. In the other monkey one injection track (no. 2) in area 17 advanced obliquely from layer I to layer IVA, and another injection track (no. 3) in area 18 (posterior lip of the lunate sulcus) included all layers and the white matter as the capillary proceeded gradually deeper. After a post-injection survival time (no. 1, 40 min; no. 2, 55 min; no. 3, 35 min) the animals were perfused with fixative and slices of the injected cortex processed for Golgi staining and gold toning, as described previously16. Semi-thin (1 µm) sections perpendicular to the injection track were cut from the Golgi sections and processed for autoradiography<sup>11</sup>. Golgi staining was used to reveal the processes of some of the GABA-accumulating cells, but because of the unreliability of the staining, no unequivocal identification of the cell type of neurones labelled in the upper layers has yet been obtained.

Neurones in each of layers I-VI in both areas 17 and 18 became labelled when the layer was injected with <sup>3</sup>H-GABA. The number of labelled cells gradually decreased in all directions from the injection track, but labelled cells could always be found above the capillary track up to and including layer II. A distinct, bimodal pattern of labelled neurones and fibres was observed when the injection track passed through lower layer V, layer VI and the superficial white matter (injections 1 and 3; Fig. 1a). Large labelled neurones were seen around the injection site with scattered neurones as far as 1-1.5 mm from the injection site in layers V and VI. Occasionally, labelled neurones were found in layer IV and lower layer III, always above the injection track. In addition, another group of strongly labelled small, mainly fusiform cells was observed in layers II and upper III (Fig. 2a, b). The quantitative distribution of the neurones labelled by one oblique penetration in area 17 is shown in Fig. 1b.

It is unlikely that the neurones in the upper group were labelled by GABA taken up from the extracellular space in the upper layers, because there were very few labelled neurones in lower layer III and layer IV, although these layers contain a

large number of GABA-accumulating neurones when injected directly. A more likely explanation is that the neurones in layers II and upper III were labelled by retrograde axonal transport of <sup>3</sup>H-GABA from the injection site in the deep layers. This is supported by the observation that strongly labelled fibre bundles pass through layers IV and lower III (Fig. 2c).

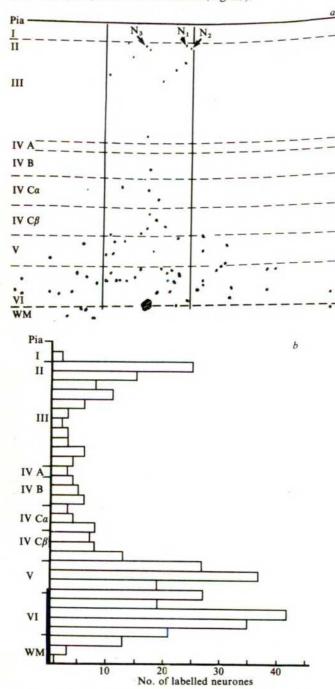

Fig. 1 a, Location of labelled neuronal perikarya (dots) in a single section of monkey striate cortex after 3H-GABA injection at the border of layer VI and the white matter. The drawing is of a section perpendicular to the pial surface; the injection was made obliquely at an angle of almost 90° to the plane of the section. Besides the large labelled neurones around the injection track (shaded area) and a few neurones in layer IV, there is a group of small labelled neurones in layer II and upper layer III. N1-N3 are shown on light micrographs in Fig. 2. Note the vertical alignment or labelled neurones above the injection track. The vertical lines enclose a 500 µm column in which cells were counted for b. b. Distribution of 393 3H-GABA-labelled cells in all layers (I-VI) of the striate cortex, counted in 13 semi-thin sections cut perpendicular to the injection track at different levels of injection no. 1, Thick vertical line represents the levels where 3H-GABA was injected. WM, white matter.

What type of neurones in the upper layers accumulate GABA from the deeper layers? There is a very strong projection from layer II to layer V in area 17 of the monkey, mediated by small pyramidal cells<sup>17</sup>. Thus the terminals of these neurones could take up the injected GABA. As pyramidal and stellate neurones can be differentiated on the basis of fine structural criteria, we studied the characteristics of six labelled neurones from the upper layers. After localizing the labelled neurones in semi-thin sections, a series of 84 and 132 ultrathin sections, respectively, were cut from two blocks containing the remainder of the perikarya of the labelled neurones. Using electron microscopy we found that labelled neurones had an indented eccentric nucleus with dense clumps of chromatin. There were many free polyribosomes in the cytoplasm, making the cell conspicuously electrodense. The thin dendrites emerging from the perikarya contained densely packed microtubules (Fig. 2d) and some of the dendrites were beaded, receiving predominantly asymmetric

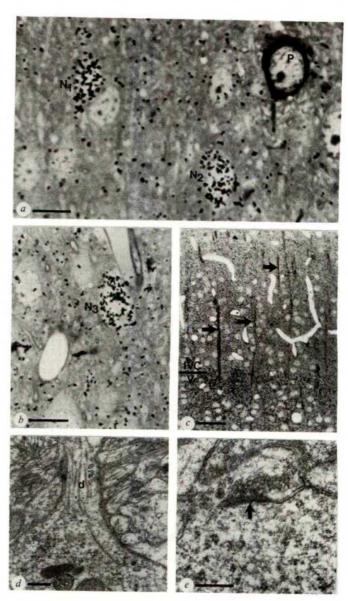

Fig. 2 Light (a-c) and electron microscopic (d,e) details from the area shown in Fig. 1a. a, b, Semi-thin sections of  ${}^{3}\text{H-GABA-labelled}$  neurones  $(N_{1}-N_{3})$  in layer II, which were also serially sectioned for electron microscopy. One Golgi-stained pyramidal cell (P) is also present. c, Vertical labelled fibre bundles (arrows) passing through layer IVC. d, Origin of a small dendrite (d) from the neurone  $N_{3}$  directed towards the pia. e, Asymmetric synapse on the perikaryon of the labelled neurone  $N_{2}$ . a-c, Ilford K5 emulsion; 30 days exposure. Scale bars: a, b,  $10~\mu\text{m}$ ; c,  $50~\mu\text{m}$ ; d, e,  $0.2~\mu\text{m}$ .

synapses. The perikarya received few, mainly symmetrical synapses from boutons containing pleomorphic vesicles, but occasional asymmetric synapses established by boutons containing round synaptic vesicles were also observed (Fig. 2e). All these features are characteristic of small stellate cells in the monkey primary sensory cortex<sup>18,19</sup>. For comparison we also studied two Golgi-stained, gold-toned small pyramidal cells in layer II. These neurones differed from labelled cells in that the nucleus was large, round and relatively transparent and there were few free ribosomes. Thick dendrites tapered gradually from the perikaryon and an apical dendrite was observed. The perikarya and proximal dendrites received only symmetrical synapses, confirming previous findings<sup>20,21</sup>

These data taken together provide evidence for a GABAaccumulating stellate neurone system with perikarya situated in layer II and upper layer III, and with axons descending vertically in bundles into layer V. One stellate neurone, the doublebouquet cell with tight vertical axon bundles described in previous studies<sup>22-25</sup>, corresponds very well to the above characteristics but more detailed information is required before we can conclude definitely that GABA-accumulating neurones of the upper layers are, or include, double-bouquet cells. It was shown recently25 that this neurone makes symmetrical synaptic contacts, similar to those which contain glutamic acid decarboxylase (GAD) in the monkey<sup>26</sup>, with dendritic shafts and spines. Although the axons of double-bouquet cells do not enter layer VI the fact that an injection here produces labelled neurones in layers II and III is easily explained by diffusion of the GABA across the V-VI boundary.

The presence of a GABAergic vertical neurone system passing throughout layers II to V of the visual cortex and capable of influencing neurones in layer VI with dendrites in layer V is significant in view of the functional, columnar organization of cortical neurones<sup>27</sup>. The distribution of GAD immunoreactivity in the plane of the cortical surface was recently shown to follow a pattern resembling ocular dominance columns7. On the other hand, it has been shown in area 17 that cortical neurones in a radial column are maximally excited by a bar of light or grating of a particular orientation, and that this orientation specificity is temporarily abolished by the GABA antagonist bicuculline<sup>2</sup> The columnar system of GABA-accumulating axons described here may have an important role in this specificity, as the axon bundles are highly restricted in lateral extent (20-50 µm in diameter) and could have a powerful effect locally.

We thank Miss K. Szigeti and Z. F. Kisvárday for their assistance and the MRC for its support. P.S. was supported by the Wellcome Trust.

### Agonist and antagonist benzodiazepine receptor interaction in vitro

H. Möhler & J. G. Richards

Pharmaceutical Research Department, F. Hoffmann-La Roche & Co. Ltd, CH-4002 Basle, Switzerland

A representative of a novel series of imidazodiazepines, Ro 15-1788, selectively antagonizes all major central actions of benzodiazepines by competitive, high-affinity interactions with benzodiazepine receptors (BR) in the central nervous system (CNS)1-3. Doses of Ro 15-1788 sufficient to antagonize benzodiazepine actions have been shown per se to lack pharmacological action in animals and man1-4. Thus Ro 15-1788 provides a highly selective tool for experimental investigations of BR-mediated events and is of therapeutic value in all cases where a rapid termination of benzodiazepine actions is indicated. Using <sup>3</sup>H-labelled Ro 15-1788 as radioligand in equilibrium binding studies in vitro, we show here that 3H-Ro 15-1788 interacts with the same number of BR sites as the agonist 3H-clonazepam in various brain regions. However, their mode of receptor interaction is different. In conditions which alter receptor affinity for 3H-clonazepam binding, such as addition of  $\gamma$ -aminobutyric acid (GABA) or certain ions, no change is seen in 3H-Ro 15-1788 binding. This effect can be used to distinguish between benzodiazepine receptor agonists and antagonists in vitro. Furthermore, the thermodynamics of agonist and antagonist receptor interaction are different, but only at temperatures above 21 °C.

Several lines of evidence indicate that <sup>3</sup>H-Ro 15-1788 interacts with the same central type of BR sites as benzodiazepine

(1) <sup>3</sup>H-Ro 15-1788 was bound to the same maximal number of specific binding sites  $(B_{\text{max}})$  as  $^{3}\text{H-clonazepam}$  in frozen and extensively washed synaptic membrane fractions<sup>5</sup> prepared from various brain regions. 3H-clonazepam was used as agonist because, in contrast to 3H-flunitrazepam (3H-FNZP) and 3Hdiazepam, it binds selectively to the central type of BR without interacting with the peripheral type of benzodiazepine binding sites present in brain tissue<sup>6</sup>. Scatchard analysis of <sup>3</sup>H-Ro 15-1788 and <sup>3</sup>H-clonazepam specific binding revealed only one population of binding sites in each brain area tested, with no major regional difference in the apparent affinity constant  $(K_D)$ for either radioligand (cerebral cortex: 3H-Ro 15-1788 (3Hclonazepam) specific binding,  $B_{\text{max}} = 1.7(1.6)$  pmol per mg protein,  $K_D = 0.9(0.9)$  nmol 1<sup>-1</sup>; cerebellum:  $B_{\text{max}} 0.7(0.7)$ ,  $K_D =$ 0.8(0.7); hippocampus: 1.7(1.6), 0.9(0.8); hypothalamus: 1.2(1.2), 0.9(1.0); striatum: 0.9(0.8), 1.1(1.0); midbrain: 0.9(0.7), 1.1(0.9); medulla pons: 0.6(0.5), 0.8(0.8). Values of s.e.m. from at least three determinations of  $K_D$  or  $B_{max}$  were in the range  $\pm 0.08$ –0.1. In  $^3$ H-Ro 15-1788 binding the antagonist Ro 14-7437 (1μmol I<sup>-1</sup>), which is the desfluoro analogue of Ro 15-1788, was used as displacer<sup>2</sup>. <sup>3</sup>H-clonazepam was displaced by 10 μmol l<sup>-1</sup> diazepam).

(2) Autoradiographically, the density and distribution of <sup>3</sup>H-Ro 15-1788 binding sites in sections of various CNS regions were very similar to those seen with <sup>3</sup>H-clonazepam.

(3) A variety of receptor agonists and antagonists showed very similar potency in inhibiting either 3H-clonazepam or 3H-Ro 15-1788 binding (Table 1).

(4) The inhibition of <sup>3</sup>H-Ro 15-1788 binding by diazepam or flunitrazepam was competitive1.

(5) In heat inactivation experiments, the amount of specifically bound <sup>3</sup>H-Ro 15-1788 was reduced at the same rate and to the same extent as that of 3H-clonazepam (60 °C, 5-60 min). In the presence of 10  $\mu$ mol l<sup>-1</sup> of GABA, diazepam or

Inhibition of  $^3$ H-clonazepam binding (specific activity 16.1 Ci mmol $^{-1}$ , 0.5 nmol  $l^{-1}$ ; assay: H.M., in preparation) and of  $^3$ H-Ro 15-1788 binding (specific activity 26.8 Ci mmol $^{-1}$ , 0.5 nmol  $l^{-1}$ ; ref. 2) by various BR ligands at 0 °C using freeze-thawed and extensively washed synaptic membranes $^5$  of rat cerebral cortex. The concentrations giving half-maximal inhibition (IC<sub>50</sub>) are mean values of three determinations with s.e.m. values between  $\pm 5$  and 20%. (For the structure of enantiomers Ro 11-6896 and Ro 11-6893, of CGS 8216, CL 218 872 and zopiclone, see refs 27, 22, 16 and 15, respectively.)  $\beta$ -CC,  $\beta$ -carboline-3-carboxylate.

Ro 15-1788, the binding sites for the two radioligands were similarly protected from heat inactivation (60 °C, 30 min).

(6) Ro 15-1788 did not interact with the peripheral type of benzodiazepine binding site in the brain as it was unable to displace  ${}^{3}\text{H-Ro}$  5-4864 when tested in cerebral cortex (IC<sub>50</sub> > 10  $\mu$ mol l<sup>-1</sup>)<sup>1</sup>.

Thus, Ro 15-1788 seems to interact with the same number of sites of the central BR type as benzodiazepine agonists. The mode of interaction of Ro 15-1788 with BR is, however, different from that of receptor agonists. BR affinity for <sup>3</sup>H-diazepam or <sup>3</sup>H-FNZP binding is increased in the presence of various chemicals, including  $100 \,\mu\text{mol}\,l^{-1}$  GABA<sup>8.9,28-30</sup>,  $500 \,\mu\text{mol}\,l^{-1}$  pentobarbitone <sup>10,11</sup>,  $10 \,\mu\text{mol}\,l^{-1}$  SQ 20 009 (ref. 12),  $2 \,\text{mmol}\,l^{-1}\,\text{NiCl}_2$  (ref. 13),  $20 \,\text{mmol}\,l^{-1}\,\text{NH}_4\text{I}$ ,  $200 \,\text{mmol}\,l^{-1}\,\text{NH}_4\text{Cl}$  or  $100 \,\text{mmol}\,l^{-1}\,\text{NH}_4\text{Br}$  (ref. 14), while the BR affinity is decreased in the presence of 50 mmol  $l^{-1}\,$  (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> or  $200 \,\text{mmol}\,l^{-1}\,$  ammonium acetate <sup>14</sup>. However, in parallel assays, neither the  $K_D$  nor the  $B_{\text{max}}$  value for <sup>3</sup>H-Ro 15-1788 binding was affected by these agents. This lack of susceptibility of <sup>3</sup>H-Ro 15-1788 binding to conformational changes of BR may reflect the inability of Ro 15-1788 to induce a conformational change of the receptor and, thereby, to trigger a biological response

of the receptor and, thereby, to trigger a biological response. The different responses of <sup>3</sup>H-agonist and <sup>3</sup>H-Ro 15-1788 binding to alterations in BR affinity can be used to distinguish in vitro between agonists and antagonists; the inhibitory potency of a ligand is determined in <sup>3</sup>H-Ro 15-1788 binding in the presence and absence of a compound such as GABA which is known to alter the affinity for agonists. At 35 °C the addition of 100 μM GABA increased two- to threefold the inhibitory potency (IC<sub>50</sub>) of various BR agonists such as flunitrazepam, diazepam, oxazepam, zopiclone <sup>15</sup> and Cl 218 872 (ref. 16) in <sup>3</sup>H-Ro 15-1788 binding, while the inhibitory potency of various antagonists remained unaltered, as shown for the selective antagonists Ro 15-1788 and Ro 14-7437 (Fig. 1) and for CGS 8216 and ethyl-β-carboline-3-carboxylate, which block non-selectively at least some benzodiazepine actions <sup>17-22</sup>. The inhibitory potency of methyl-β-carboline-3-carboxylate, an

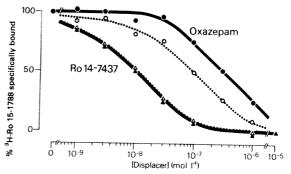

Fig. 1 Inhibition of <sup>3</sup>H-Ro 15-1788 binding in the presence (open symbols) and absence (solid symbols) of 100 µmol 1 GABA, by the agonist oxazepam (circles) and the antagonist Ro 14-7437 (triangles) at 35 °C using freeze-thawed and extensively washed synaptic membranes of rat cerebral cortex. IC<sub>50</sub> values ± s.e.m. of at least three determinations in the absence (presence) of GABA were: flunitrazepam 27.6±6 (8.2±0.3 P<0.02); diazepam 94± 11 (32.5 ± 5.0; P < 0.01); zopiclone  $160 \pm 10(97 \pm 10; P < 0.02)$ ; oxazepam  $315 \pm 10$  ( $116 \pm 14$ ; P < 0.01); CL 218  $872:560 \pm 30$  $(350\pm20; P<0.01)$ . Ro 15-1788:  $7.4\pm0.8$   $(6.9\pm0.5)$ ; Ro 14-7437:  $13.2 \pm 1.9$  (14.6  $\pm 0.3$ ); CGS 8216:  $0.44 \pm 0.1$  (0.61  $\pm 0.1$ ); propyl- $\beta$ -CC: 11.9  $\pm$  0.3 (11.6  $\pm$  0.4); ethyl- $\beta$ -CC 5.5  $\pm$  0.8 (7.9  $\pm$ 0.6), all with no significant difference by Student's t-test. Methyl- $\beta$ -CC,  $8.8 \pm 0.8$  (14.8  $\pm$  1.0; P < 0.02). Similar results were obtained at 0 °C, except that the IC50 values of zopiclone and methyl-β-CC remained unchanged in the presence of GABA.  $\beta$ -CC,  $\beta$ -carboline-3-carboxylate.

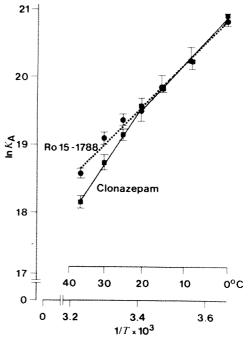

Fig. 2 Van't Hoff plot of the dependence of  $K_{\rm A}$  of  $^3{\rm H-Ro}$  15-1788 and  $^3{\rm H-clonazepam}$  binding on temperature (T), using frozen and extensively washed synaptic membranes of rat cerebral cortex. Each point represents the mean  $(\pm\,{\rm s.e.m.})$  of three determinations. The apparent dissociation constant  $K_{\rm D}$   $(1/K_{\rm A})$  for  $^3{\rm H-clonazepam}$   $(^3{\rm H-Ro}$  15-1788) at 0 °C were:  $0.86\pm0.03$   $(0.87\pm0.07)$  nmol  $1^{-1}$ ; at 7.5 °C:  $1.68\pm0.2$   $(1.72\pm0.33)$ ; 15 °C:  $2.46\pm0.12$   $(2.48\pm0.41)$ ; 20 °C:  $3.25\pm0.38$   $(3.55\pm0.46)$ ; 25 °C:  $4.92\pm0.39$   $(3.98\pm0.35)$ ; 30 °C:  $7.46\pm0.78$   $(5.16\pm0.42)$ ; 37 °C:  $13.2\pm1.3$   $(8.64\pm0.57)$ . The  $B_{\rm max}$  values did not change with temperature. The thermodynamic parameters for  $^3{\rm H-clonazepam}$   $(^3{\rm H-Ro}$  15-1788) binding at 37 °C were:  $\triangle G^0 = -11.20$  (-11.46) kcal mol $^{-1}$ ;  $\triangle H^0 = -14.98$  (-9.87) kcal mol $^{-1}$ ;  $\triangle S^0 = -12.20$  (-5.12) EU. The parameters at 0 °C were:  $\triangle G^0 = -11.34$  (-11.34) kcal mol $^{-1}$ ;  $\triangle H^0 = -10.34$  (-9.87) kcal mol $^{-1}$ ;  $\triangle S^0 = +3.65$  (+5.3) EU (entropy units).

antagonist having convulsant activity23, was even decreased in the presence of GABA (see Fig. 1 legend). This test may be relevant not only for differentiating agonists from antagonists, but also for evaluating mixed agonist-antagonists.

The thermodynamics of the receptor binding reaction for Ro 15-1788 differ from those of clonazepam as shown by the change in standard Gibbs free energy ( $\Delta G^{\circ}$ ), in entropy ( $\Delta S^{\circ}$ ) and enthalpy  $(\Delta H^{\circ})$  determined as described elsewhere<sup>2</sup> van't Hoff plot, from which  $\Delta H^{\circ}$  is calculated, showed an inclination point at 21 °C for 3H-clonazepam binding (as for other agonists<sup>25,26</sup>) but was linear for <sup>3</sup>H-Ro 15-1788 (Fig. 2). Above 21 °C, <sup>3</sup>H-clonazepam binding was associated with a large decrease in enthalpy which compensated for an unfavourable decrease in entropy. 3H-Ro 15-1788 binding, however, was enthalpy- as well as entropy-driven (see Fig. 2 legend). These

findings agree with a two-step model of receptor binding, as proposed for other receptors<sup>24</sup>:  $L+R \stackrel{(1)}{\longrightarrow} LR \stackrel{(2)}{\longrightarrow} LR'$  where L is the ligand and R the receptor. Agomsts and antagonists may bind in reaction (1) with similar thermodynamic components. Due to their structural properties, agonists, but not antagonists, can participate in reaction (2) by inducing a conformational change of the receptor to R'. This conversion is thought to be associated with negative enthalpy and entropy components. Below the temperature of 21 °C, at which phase transitions of membrane lipids are known to occur, the thermodynamic parameters of <sup>3</sup>H-clonazepam binding were almost identical to those of <sup>3</sup>H-Ro 15-1788 binding (see Fig. 2 legend). Possibly the agonist-dependent change in BR conformation cannot be induced at temperatures <21 °C.

We thank Dr W. Haefely for critical reading of the manuscript.

#### Immunohistochemical mapping of vitamin D-dependent calcium-binding protein in brain

Sohan S. Jande & L. Maler

Department of Anatomy, University of Ottawa, Ottawa, Ontario, Canada K1N 9A9

#### D. Eric M. Lawson

Dunn Nutritional Laboratory, University of Cambridge and Medical Research Council, Milton Road, Cambridge CB4 1XJ, UK

The steroid hormone, 1, 25-dihydroxycholecalciferol (1, 25-(OH)2D3) causes the de novo synthesis of a calcium-binding protein (D-CaBP)1,2. This protein is present in highest concentrations in intestine, kidney and shell gland, across which calcium is transported in relatively large amounts, but it is also found in smaller amounts in several other tissues, including brain<sup>3-7</sup>. The area of brain with the highest D-CaBP concentration is the cerebellum, where the protein is found only in the Purkinje cells<sup>7,8</sup>. We have now mapped D-CaBP immunohistochemically throughout the brain of chicks and rats and present here a list of all positive nuclei. Because certain of these neurones also contain 1, 25-(OH)<sub>2</sub>D<sub>3</sub> (ref. 9), we suggest that they are target cells for this hormone, thus broadening the functional significance of vitamin D to include the brain and implicating vitamin D in a more widespread action than simply a role in the calcium translocation mechanism of epithelial cells.

Intestinal D-CaBP from both birds and animals has been well characterized with respect to its molecular weight, calciumbinding constants and electrophoretic mobility 1,10,11. D-CaBP from chick brain resembles that of chick intestine immunologically, in molecular weight and in electrophoretic mobility and is "indeed the same protein" 12. The antisera against chick intestinal D-CaBP give precipitin lines with rat and bovine brain D-CaBP<sup>13</sup> and consequently rat brain can also be stained for this protein. We have taken sections from every area of rat and chick brains and assessed them for D-CaBP-positive nuclei by an immunoperoxidase technique8. The protein was found in various cells throughout the brain of these two species but only in neuronal elements and never in glial, endothelial or ependymal cells. Within any brain region it was always localized in certain specific neuronal types (Table 1 and Fig. 1a-c)

There seems to be no common factor between the D-CaBPpositive neurones listed in Table 1 that could suggest a function for this protein. However, in three locations, on the basis of electrophysiological data available, there seems to be a special need for calcium regulation. The Purkinje cells of the cerebellum<sup>14,15</sup>, the neurones of the inferior olive<sup>16</sup> and CA1 pyramidal cells of the guinea pig hippocampus<sup>17</sup> produce voltage-dependent calcium spikes within their dendritic trees. These then induce the usual sodium-dependent action potentials from the soma-initial segment of each of these neurones. All the neurones contain D-CaBP, both in their soma and dendrites (Fig. 1a-c). The pyramidal neurones of CA3 also produce voltage-dependent calcium currents<sup>17</sup> in their dendrites but do not contain D-CaBP. However, an important electrophysiological difference between CA1 and CA3 neurones is that although calcium currents induce bursts of spikes in both CA1 and CA3 pyramidal dendrites, in CA3 pyramids these bursts propagate to the soma, whereas in CA1 a dendritic burst produces only a single somatic spike. Perhaps D-CaBP, by regulating intracellular calcium levels, is limiting the temporal and spatial spread of calcium currents, thereby preventing or modifying bursting activity. It is thus possible that the presence of D-CaBP in a neurone is indicative of voltagedependent calcium currents in that cell; however, this idea must be tested by intracellular recording from at least some of the cell types listed in Table 1. The pyramids of CA3, however, make it clear that calcium spikes need not imply the presence of D-CaBP. This situation may be quite common because D-CaBP was not found in dorsal root ganglia, although some ganglion cells can produce calcium spikes18

If cells containing CaBP are to be regarded as target cells for 1,25-(OH)<sub>2</sub>D<sub>3</sub>, they should also contain this hormone in addition to one of the products of its action. Combining the results of this study with those 9,19 on the autoradiographic localization of 1,25-(OH)<sub>2</sub>D<sub>3</sub>, which used the atlas of Konig and Klippel<sup>26</sup> following sites in brain contain both the hormone and D-CaBP: amygdala, nucleus pariventricularis, nucleus parataenialis in the thalamus and some neurones in the nucleus spinalis caudalis of the nervous trigeminus. Although low uptake of labelled

Monospecific antiserum was raised against chick duodenal D-CaBP purified to electrophoretic homogeneity by the original method of D-CaBP isolation<sup>24</sup>. Brain sections (7 µm) were prepared from paraffin-embedded material after fixation with Carnoy (for rationale of fixation and further details of the technique, see ref. 8). Antiserum was used at 1:10 dilution, while goat anti-rabbit y-globulin conjugated with peroxidase (Miles) was diluted as 1:50. Treatment with 3,3'-diaminobenzidine was for 15 min. Control sections were stained with normal rabbit serum and with supernatant from antigen and antiserum mixed in proportions of equivalence point. Other sections were stained with cresyl violet. The concentration of D-CaBP was ascertained only visually and is expressed as +++, ++ and +. +++ Implies a dense reaction in the somata which was also easily visible in the dendrites, axons and their terminals<sup>8</sup>, while + indicates a lesser reaction in the perikaryon which may extend into the processes but was not easily detectable there. ++ Implies an intermediate situation where the reaction product was quite dark in the somata and was easily detectable in the processes but only in their proximal parts. Unless otherwise mentioned (for example, scattered cells), all neurones in each nucleus stained for D-CaBP. Those regions for which there is good comparative anatomical evidence for homology are marked = whereas regions which are not known to be homologous are listed separately. Nomenclature for the brains is drawn primarily from the atlases of Karten and Hodos<sup>25</sup>, and Pellegrino et al.<sup>26</sup>.

hormone has been demonstrated in the spinal cord, no D-CaBP was detected.

There is therefore an encouraging correlation of identity of the target cells by the two techniques, for it must be remembered that all D-CaBP-containing cells, because of the dependency of this protein on vitamin D in the intestine, must be target cells, whereas all target cells need not be positive for D-CaBP, as the synthesis of this protein may not be the response of such cells to vitamin D stimulation. However, D-CaBP is present in many

other organs<sup>5,6</sup> and in some cases the cell types have been identified<sup>8,21</sup>. Evidence for the view that a wide range of tissues have target cells for 1,25-(OH)<sub>2</sub>D<sub>3</sub> is provided by the autoradiographic localization of the hormone in cells which also contain D-CaBP<sup>9,19,22</sup>, only a few of which occur in the central nervous system. Initial studies with epithelial tissues such as the intestine and shell gland have connected the function of D-CaBP with transcellular calcium transport, as seen in calcium absorption or egg shell formation<sup>23</sup>. This view is clearly not

Fig. 1 a-c, Transverse sections of rat hippocampus, stained with antiserum. In power view (a) the dark reaction product indicating the presence of D-CaBP is seen in discrete sites. The blank areas serve as internal controls. For orientation, D and V denote dorsal and ventral sides of the brain. The D-CaBP is seen in the granule cells of the dentate gyrus (DG) and their mossy fibre efferents (mf). Pyramidal cells (small arrows) within CA1 are also positive. b Shows a higher magnification of the area about the large arrow in a, illustrating the abrupt transition between CA1 and CA2. Note that whereas pyramidal cells of CA1 (small arrows) are positive, pyramidal cells of CA2 as well as CA3 (P in a) and their Schaeffer collaterals within CA1 are devoid of D-CaBP. c, A further higher magnification view of CA1 shows the reaction product in both apical and basilar dendrites (arrow heads) of CA1 pyramidal cells. Note that some neurones do not show any reaction product (asterisk). It is not known whether these are pyramidal cells or another type of cell (for example, basket cells). Scale bars in a, b and c represent 300, 100 and 40 µm respectively. d, Control, similar to a but from section stained with normal rabbit serum.

supported by the presence of D-CaBP in so many cell types uninvolved in such processes. It may be that D-CaBP is involved in more than one physiological function, in which case it might have a single molecular action which has been incorporated into

# Evidence that types I and II interferons have different receptors

#### Andrew A. Branca & Corrado Baglioni

Department of Biological Sciences, State University of New York at Albany, Albany, New York 12222, USA

Interferons (IFNs) are a class of proteins, secreted by animal cells in response to various inducers1, which confer resistance to viral infections and are designated according to their cellular origin or to the inducing agent. Viruses induce type I interferon, subdivided into  $\alpha$ -interferon, produced by leukocytes (Le) or lymphoblastoid (Ly) cells, and  $\beta$ -interferon, produced by fibroblasts1. Mitogens and antigenic stimuli induce in lymphocytes type II immune IFN-y. Interferons seem to bind to specific receptors<sup>2</sup> to elicit a variety of cellular responses<sup>3</sup>; several early studies provided indirect evidence for such binding4-6. Direct evidence for specific interferon receptors was presented by Aguet<sup>7</sup>, who showed that biologically active <sup>125</sup>I-labelled mouse (Mu)IFN binds to sensitive L1210-S cells, but not to interferonresistant L1210-R cells8. The main obstacle in carrying out such studies is the availability of pure interferon. Recently, Maeda et constructed plasmids containing human interferon sequences. The plasmid p104 was used as a probe to isolate the coding region of a human interferon (IFLrA), which was expressed in Escherichia coli<sup>16</sup> and purified with monoclonal antibodies<sup>11</sup>. This interferon, designated HuIFN- $\alpha$ A, was labelled with 125 I for binding assays on human cells. We have determined the specificity of different HulFNs for the cellular sites which bind HuIFN-αA and show here that HuIFN-γ does not compete for binding, whereas all type I HuIFNs do.

The HuIFN- $\alpha$ A was iodinated in conditions designed to minimize the concentration of  $H_2O_2$  in the reaction (Fig. 1). The high stability of the interferon allowed prolonged incubation and resulted in retention of biological activity. The <sup>125</sup>I-labelled HuIFN- $\alpha$ A had a specific activity of ~50 mCi per mg and an antiviral titre in different experiments of 50-75% of the unreacted interferon, when assayed within a week after iodination. The HuIFN- $\alpha$ A was iodinated in ~15% of the tyrosine residues, as determined from the specific activity of <sup>125</sup>I and the recovery of labelled protein. As there are four tyrosines per HuIFN- $\alpha$ A molecule<sup>12</sup>, at most 60% of the molecules were mono-iodinated. We have as yet no information on the proportion of molecules having different degrees of iodination.

The product of these iodination reactions showed a major molecular weight  $(M_{\rm r})$  component of  $\sim 20,000$  (as calculated from the DNA sequence  $^{12}$ , HuIFN- $\alpha$ A has a  $M_{\rm r}$  of 19,390) and traces of other components, when analysed by gel electrophoresis (Fig. 1). This preparation was further fractionated by chromatography on Sephadex G-75 and the fractions analysed by gel electrophoresis and for antiviral activity (Fig. 1). A single peak of antiviral activity was eluted, corresponding to the major peak of radioactive protein. This peak was well separated from iodinated bovine serum albumin (BSA), which represented the major protein contaminant. Some carrier BSA was presumably iodinated when added after inhibiting the reaction with NaN<sub>3</sub> (see Fig. 1 legend). The fractions containing  $^{125}$ I-HuIFN- $\alpha$ A were combined and used in subsequent experiments.

We investigated the interaction of  $^{125}\text{I-HuIFN-}\alpha\text{A}$  with cellular binding sites by incubating it with suspensions of human cells in tissue culture. At the end of the incubation, the cells were centrifuged through two sucrose layers. and the radioactivity sedimenting with the cell pellet was measured (Table 1). Greater binding was obtained with Daudi cells than with the other lymphoblastoid cells tested or with HeLa cells. Therefore, we used Daudi cells in all further experiments. Even with these cells, relatively small amounts of  $^{125}\text{I-HuIFN-}\alpha\text{A}$  were bound and the assays were carried out with 4–10 ml of cell suspension.

Binding was extremely reproducible: each preparation of labelled interferon gave essentially identical results when tested in standard conditions for several weeks, despite some decline in antiviral activity.

The time course of binding at 0 °C and 37 °C is shown in Fig. 2a. There was very little binding at 0°C, whereas at 37°C substantial binding occurred which reached a plateau after ~1 h. All subsequent experiments were carried out at 37 °C, the temperature of the cell cultures. 125I-HuIFN-αA binding approached saturation when increasing concentrations were incubated with a standard cell aliquot; a Scatchard analysis of these data gave an apparent single affinity constant of  $7 \times$ 10° M<sup>-1</sup> (Fig. 2b). This binding was abolished when large amounts of HuIFN- $\alpha$ (Le) were included in the incubations (Fig. 2b). These results indicate that the binding involves specific cellular sites. The number of binding sites per cell, calculated from the intercept with the abscissa in the Scatchard plot14, is -5,000. These observations are consistent with the binding of <sup>125</sup>I-HuIFN- $\alpha$ A to cellular receptors, although the identification of a specific receptor would require its characterization as a macromolecular complex with interferon or its purification. For

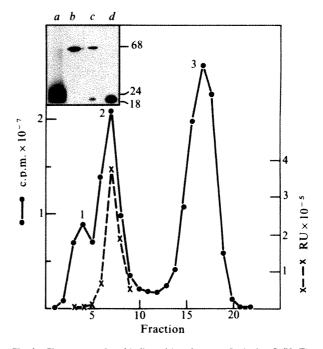

Fig. 1 Chromatography of iodinated interferon on Sephadex G-75. The HuIFN-αA was purified by Dr Sidney Pestka (Roche Institute of Molecular Biology) on an affinity column of monoclonal antibodies to a specific activity of  $2\times10^8$  U per mg. It was iodinated in a reaction containing in 0.1 ml: 2.2  $\mu$ g HuIFN- $\alpha$ A, 12.5  $\mu$ M Na<sup>125</sup>I (2.5 mCi,  $\sim$ 2,000 Ci mmol<sup>-1</sup>), 10  $\mu$ l of hydrated Enzymobead iodination reagent (Bio-Rad) containing immobilized glucose oxidase and lactoperoxidase, 0.3%  $\beta$ -D-glucose and phosphate-buffered saline (PBS) pH 7.0. The reaction was stopped after 24 h by the addition of 0.2 M NaN3. After 15 min, 0.2 mg of BSA in 0.1 ml PBS was added and the sample applied to a  $2.5\times0.7\,\mathrm{cm}$  column of Sephadex G-10 equilibrated with PBS containing 1 mg ml $^{-1}$  BSA (buffer A). This column was washed with 1 ml of buffer A and the cluate applied to a  $25\times0.7\,\mathrm{cm}$ column of Sephadex G-75 equilibrated with buffer A. The column was eluted at a flow rate of 6 ml h<sup>-1</sup> and 0.44-ml fractions were collected. All these operations were carried out at room temperature. The column fractions were stored at 4 °C and analysed for radioactivity ( ) and antiviral activity (×). The latter was measured by the protection of monolayers of the human lung carcinoma cell line A549 from infection with encephalomy-ocarditis virus. Monolayers in multi-well plates were infected with  $4\times10^5$ plaque-forming units of virus and the cytopathic effect quantitated by a viral dye uptake method<sup>22</sup>. The HuIFN- $\beta$  standard (G-023-902-527, obtained from NIH) was used as a reference and the antiviral titre is expressed in NIH room NH) was used as a reference and the ainth at other is expressed in NH? reference units (RU). Column fractions were also analysed by electrophoresis on 15% polyacrylamide slab gels<sup>23</sup>. The autoradiographs are shown in the top left corner: a, unfractionated <sup>125</sup>I-HuIFN- $\alpha$ A; b, peak 1; c, fraction 5; d, peak 2. About 10,000 c.p.m. of each fraction and 100,000 c.p.m. of unfractionated interferon were analysed. The molecular probability in the exercise of protein standards run in applied is indicated at the weight (in thousands) of protein standards run in parallel is indicated at the right-hand side: 68, BSA; 24, trypsinogen; and 18,  $\beta$ -lactoglobulin. Peak 3 is free  $^{125}I^-$ .

Table 1 Binding of <sup>125</sup>I-labelled interferon to human cells

Cell line	125I-HuIFN-αA bound (c.p.m.)
Daudi	880
Raji	270
Molt-4	260
HeLa	310

The lymphoblastoid cells were grown in stationary cultures or in roller bottles in Dulbecco's medium with 10% horse serum; HeLa cells were grown in spinner cultures in Eagle's medium supplemented with 7.5% calf serum. Each assay contained in 5 ml of culture medium:  $2.5 \times 10^6$  cells and 2 ng of <sup>125</sup>I-HuIFN- $\alpha$ A ( $\sim$ 60,000 c.p.m.). After 1 h at 37 °C the samples were applied over two 4-ml layers of ice-cold 5 and 10% sucrose in buffer A and centrifuged at 20,000g for 2 min<sup>13</sup>. The pellet obtained was counted in a  $\gamma$ -counter.

convenience, the cellular binding sites for HuIFN- $\alpha A$  are referred to as receptors.

The observation that unlabelled interferon abolished the binding of <sup>125</sup>I-HuIFN-αA led us to assay different interferons in competition experiments (Fig. 3). The HulFNs used differed widely in purity, and antiviral activities had been measured in different laboratories. We determined the antiviral titre using the standard assay described in Fig. 1 legend. The competition with unlabelled HuIFN-αA could be superimposed on that obtained with HuIFN- $\alpha(Lv)$ , whereas HuIFN- $\alpha(Le)$  competed slightly less effectively (Fig. 3a). HuIFN- $\beta$  preparations of quite different purity gave superimposable competition curves, indicating that other proteins present in the preparations do not interfere in this assay (Fig. 3b). Finally, HuIFN- $\gamma$  and MuIFNβ, which is inactive on human cells 15, competed only poorly, if at all (Fig. 3b). The competition with different HuIFN- $\beta$  samples could not be explained by the presence of contaminating HuIFN- $\alpha$  in the preparations. This was established by preincubating HuIFN- $\beta$  and HuIFN- $\alpha$ (Le) with an appropriate amount of anti-HulFN- $\alpha$ (Le) antiserum, which does not significantly cross-react with  $HuIFN-\beta$ , as previously described<sup>16</sup>. This resulted in decreased competition of the HuIFN- $\alpha$ (Le), but had no effect on HuIFN- $\beta$  competition (see Fig. 3 legend). It seems, therefore, that all type I HuIFNs compete with <sup>125</sup>I-HuIFN-aA for binding to the same receptors.

These results show that HuIFN- $\gamma$  does not bind with high affinity to HuIFN- $\alpha$ A receptors and indicate that type II interferon may interact with different receptors. Ankel *et al.*<sup>17</sup> proposed that there are two distinct classes of interferon-binding

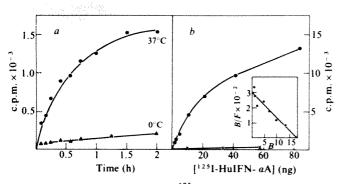

Fig. 2 Time course of binding of  $^{125}$ I-labelled interferon (a) and saturation of binding sites (b). For each time point in a,  $8\times10^6$  Daudi cells were incubated in 4 ml at the indicated temperature with 1 ng  $^{125}$ I-HuIFN- $\alpha$ A, as described in Table 1. In b,  $5\times10^6$  Daudi cells in 10 ml were incubated at 37 °C for 90 min with the indicated amount of  $^{125}$ I-HuIFN- $\alpha$ A; the c.p.m. bound per assay are indicated ( $\blacksquare$ ). Binding in the presence of  $4\times10^3$  units of HuIFN- $\alpha$ (Le) per ng HuIFN- $\alpha$ A was also determined (×). Inset shows a Scatchard plot of the data in b; B and F are concentrations of bound and free  $^{125}$ I-HuIFN- $\alpha$ A (c.p.m.× $10^{-3}$ ). The samples were centrifuged through two sucrose layers of 9 ml each, as described in Table 1 legend.

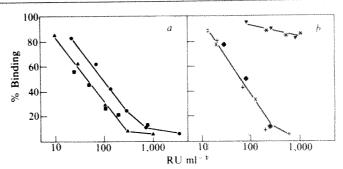

Fig. 3 Competition of different interferons with <sup>125</sup>I-HuIFN-αA for binding to Daudi cells. Incubations were as described in Fig. 2a, with the addition of the indicated concentrations of the following interferons: HuIFN-α(Le) (•; from Dr K. Cantell), HuIFN-α(Ly) (A; from Dr C. B. Anfinsen), unlabelled HuIFN-αA (■), highly purified (>10<sup>8</sup> RU per mg) HuIFN-β (\*); from Dr E. Knight Jr), two less purified samples of HuIFN- $\beta$  (×; from Dr J. Horoscewicz, 106 RU per mg; and +; from the Interferon Working Group of the NCI, 3×10<sup>5</sup> RU per mg). HuIFN-y (♥), purified as described elsewhere<sup>24</sup>, was given by Dr J. Vilček and Dr Y. K. Yip, and MuIFN-β (\*) was a gift from Dr Peter Lengyel (this preparation was purified to  $> 10^8$  RU per mg (ref. 15) and was neutralized using anti-MuIFN- $\beta$  antiserum<sup>25</sup> in Dr Lengyel's laboratory). The results are plotted as % binding relative to an assay with no added competitor. As a control for the specificity of the competition, 2,000 RU of HuIFN-α(Le) or HuIFN-β in 0.1 ml were incubated with 20 µl anti-HuIFN- $\alpha$ (Le) antiserum at 37 °C for 30 min and then overnight at 0 °C, as described elsewhere <sup>16</sup>. These samples were tested in competition assays. The binding with HulFN- $\beta$  was 11%, unchanged relative to a sample not treated with antiserum, whereas that with HuIFN- $\alpha$ (Le) increased from 10 to 34%.

sites in mouse cells, each specific for one interferon type, on the basis of experiments with L1210-R cells selected for resistance to Type I MuIFN<sup>8</sup>; these cells responded to the antiviral and anti-growth activities of type II interferon 17. Moreover, gangliosides, which may be part of type I interferon receptors 5, inhibit the activity of type I but not that of type II interferon 17. Distinct receptors for the two interferons may account for the different pathways of induction of the 2'5'-oligo(A) polymerase elsewhere reported 18 and possibly for the potentiation of activity of one interferon type by simultaneous treatment with the other 19. Interferons of the same type, however, do not potentiate each other but show additive effects 16, as expected if they interact with the same receptor.

In these studies we measured interferon binding at 37 °C. At this temperature interferon may interact with cellular receptors in a complex way, possibly as a result of a series of metabolic events. This was suggested by the observations of Friedman<sup>4</sup>, who treated chick fibroblasts with interferon at 4 °C. Digestion with trypsin at this temperature inhibited the development of the antiviral state when the cells were shifted to 37 °C. A short incubation at 37 °C, however, apparently rendered the interferon trypsin resistant. This led Friedman<sup>4</sup> to postulate that interferon binding at 4 °C involves cell-surface sites accessible to trypsin. Aguet<sup>7</sup> previously reported that binding of <sup>125</sup>I-labelled MuIFN to L1210-S cells is markedly higher at 37 °C than at 4 °C; in this study an apparent dissociation constant  $(K_d)$  of  $1-2\times10^{-11}$  M was estimated from the interferon concentration required to reach half-saturation of binding sites. From our data we calculate a  $K_d$  of  $\sim 1.5 \times 10^{-10}$  M. These  $K_d$  values may reflect the different specific activities of the interferons:  $1 \times 10^9$  U per mg protein estimated by Aguet<sup>7</sup> for the MuIFN and  $2 \times 10^8$  U per mg for the HuIFN- $\alpha$ A. The biological significance of these differences in specific activity remains to be established.

Recent advances, in the study of many polypeptide hormones have provided guidelines for investigating their interaction with cellular receptors<sup>20,21</sup>. Interferons may be regarded as polypeptide hormones because of their role in communicating from cell to cell a specific set of instructions, which leads to a wide variety of effects<sup>3</sup>. These studies provide an initial characterization of a HuIFN-receptor interaction, and are potentially

useful in studying the role of interferons as regulators of cellular

We thank Dr Sidney Pestka for the gift of purified interferon produced in E. coli, the colleagues who have donated samples of various interferons, Susan B. D'Alessandro for help in some experiments and Dr Timothy W. Nilsen for discussions and criticism of this manuscript. This work was supported by American Cancer Society grant CD-103, and NIH grants CA29895 and AI16076.

#### Type C virus particles in a cord T-cell line derived by co-cultivating normal human cord leukocytes and human leukaemic T cells

Isao Miyoshi\*, Ichiro Kubonishi\*, Shizuo Yoshimoto\*, Tadaatsu Akagi†, Yuji Ohtsuki†, Yukimasa Shiraishi‡, Kinya Nagata§ & Yorio Hinuma§

Departments of \*Medicine, †Pathology and ‡Anatomy, Kochi Medical School, Kochi 781-51, Japan §Institute for Virus Research, Kyoto University, Kyoto 606, Japan

A recent nationwide survey of the lymphocyte subpopulations of leukaemia and lymphoma in Japan has disclosed a high incidence of adult T-cell leukaemia (ATL)1. One of the striking features of this disease is the clustering of patients in the southwestern part of Japan 1,2. We have established a continuous culture line of leukaemic T cells from a patient with ATL 3.4. This cell line, MT-1, was found to carry type C virus particles and ATL-associated antigens (ATLA) which specifically reacted with sera from all ATL patients and about 25% of healthy adults in the endemic area5. We report here that by co-culture of ATL cells from a female patient and normal human cord leukocytes from a male infant, a T-cell line of cord leukocyte origin was established. Numerous type C virus particles as well as ATLA were detected in this cell line.

A 45-yr-old woman was admitted to the hospital with generalized lymphadenopathy and hepatosplenomegaly. Her blood leukocyte count was 207,300 per mm3, with 93% abnormal lymphoid cells having indented or lobulated nuclei. Most of these cells formed spontaneous sheep erythrocyte rosettes. Peripheral leukocytes separated by Ficoll-Conray gradient centrifugation were cultured in 35-mm Petri dishes (3 ml per dish) with RPMI 1640 medium supplemented with 10% human cord serum, 10% fetal calf serum and antibiotics. The initial cell density was adjusted to 5×106 per ml. The cultures were incubated at 37 °C in a humidified 7.5% CO2 atmosphere and fed twice a week. After 2 months of culture, the number of cells decreased considerably and the cells were co-cultured with umbilical cord leukocytes ( $1 \times 10^6$  per ml) from a male infant, with the hope of stimulating the growth of ATL cells. After 2 months of co-culture, a lymphoid cell line was established that was transferable every 3-5 days. This cell line, MT-2, grew in suspension forming clumps of cells and has been maintained in continuous culture for 1.5 yr. No T-cell growth factor was used. Unexpectedly, cytogenetic studies on MT-2 showed a normal male karyotype and its cord leukocyte origin was determined. MT-2 cells expressed complement receptors and Ia antigens in addition to having sheep erythrocyte receptors and T-cell membrane antigens. The cultured cells were negative for Epstein-Barr virus nuclear antigen. The establishment and characteristics of this cell line have been briefly reported elsewhere6

The acetone-fixed cells were examined for ATLA by indirect immunofluorescence using ATL patients' sera and fluorescein isothiocyanate (FITC)-conjugated goat anti-human IgG as previously described<sup>5</sup>. The MT-2 line gave a positive reaction with three reference sera from ATL patients but not with three negative control sera. Almost 100% of cells showed brilliant staining in the periphery of the cytoplasm at a serum dilution of 1:10 (Fig. 1). Unfixed MT-2 cells were similarly stained by the indirect immunofluorescence method and almost all the cells exhibited surface membrane fluorescence with the positive reference sera. These reference sera, however, did not react with various human haematopoietic cell lines, including six T-cell lines (HPB-ALT, HPB-ALL, TALL-1, RPMI 8402, Molt-4 and CCRF-CEM), four B-cell lines (Raji, Wil-2, TL-1 and BALL-1) and four non-T non-B cell lines (HL-60, NALL-1, HPB-NULL and K-562). Of these, TALL-1, BALL-1 and NALL-1 are acute lymphoblastic leukaemia cell lines established by us and maintained in our laboratory in the same conditions as used for MT-2. This would exclude the possibility that some serum component(s) or other exogenous products in the culture medium elicited the immunofluorescent reaction. Thin-section electron microscopy of MT-2 cells revealed numerous type C virus particles in the extracellular spaces (Fig. 2). The virus particles which were predominantly mature were between 85 and 145 nm in diameter. The mature virus particles consisted of an electron-dense nucleoid and an outer membrane. The immature virus particles were doughnutshaped with an electron-luscent centre. Virus particles budding from the cell membrane were rarely observed.

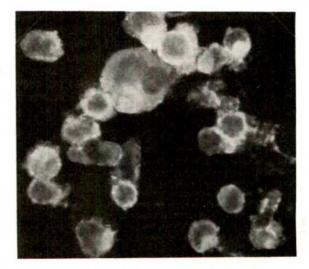

Fig. 1 Immunofluorescence micrograph of acetone-fixed MT-2 cells showing ATLA in the cytoplasm with brighter fluorescence in the periphery. All the cells, including giant cells, are fluorescent. The cells were first reacted with serum from an ATL patient and then incubated with FITC-conjugated goat anti-human IgG. ×750.

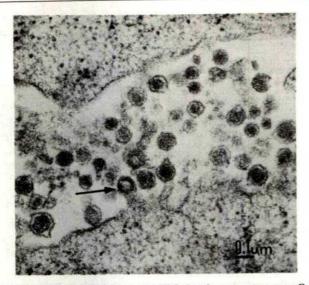

Fig. 2 Electron micrograph of MT-2 showing numerous type C virus particles in the extracellular space. One particle is budding from the cell membrane (arrow). The cells were fixed in 3% glutaraldehyde and 1% osmium tetroxide and embedded in epoxy resin. Thin sections were stained with uranyl acetate and lead citrate. ×59,000.

Fresh ATL cells from the patients do not express ATLA; this antigen expression and type C virus production occur spontaneously after several days of in vitro culture (Y.H., unpublished observation). This is consistent with persistent association of ATLA and type C virus particles in a cultured ATL cell line MT-1 (ref. 5). It is postulated, therefore, that during co-culture of ATL cells and normal human cord leukocytes, a type C virus or its genome was transmitted from ATL cells to cord T cells by extracellular or cell-to-eell infection and that the infected T cells were transformed into the virus-producer cell line MT-2. The presence of exclusively ATLA-positive cells and numerous virus particles in MT-2 is indeed significant because MT-1 contained only a few per cent of ATLA-positive cells and rare virus particles5. Consistent with the present report, we have recently characterized another T-cell line derived from cord blood lymphocytes by co-cultivation with ATL cells from a different patient. This cell line also harbours abundant type C virus particles and ATLA (manuscript in preparation). Contamination of our cells by animal oncoviruses is unlikely, as neither these viruses nor murine cells have been handled in our laboratory for several years. According to Barbacid et al.7, human sera recognized glycoproteins of animal oncoviruses grown in rodent or carnivore cells but not those of the same viruses grown in

The present results strongly suggest that the type C virus we have detected in our cell lines is aetiologically related to ATL. Recently, Poiesz et al.8 also isolated a type C retrovirus in a T-cell line derived from a patient with cutaneous T-cell lymphoma (mycosis fungoides). Thus, these independent observations in the United States and Japan lead us to think that at least certain T-cell malignancies may be caused by a closely related, if not identical, viral agent.

This work was supported by grants-in-aid from the Ministry of Education, Science and Culture, and from the Ministry of Health and Welfare of Japan.

The product of the Rous sarcoma virus (RSV) transforming gene, src, is a phosphoprotein of molecular weight  $(M_r)$  60,000 (pp60src)1-3 that is responsible for cell transformation as well as fibrosarcoma formation in a variety of animals<sup>4,5</sup>. Several experiments suggest that pp60<sup>arc</sup> is a protein kinase<sup>6-10</sup> with the unusual capacity of phosphorylating tyrosine residues 11,12, but additional evidence would be of value. Earlier studies had suggested that bacteria were unable to carry out protein phosphorylation13, although more recent findings indicate that distinct protein kinases and phosphatases are present in Salmonella typhimurium14. Despite this observation, because of the evolutionary distance, the enzymatic activities observed in bacteria are likely to be carried out by proteins unrelated to those expressed in eukaryotic cells. Thus, to study the RSV transforming protein synthesized in the absence of the variety of protein kinases expressed in normal host cells (for reviews see refs 15, 16), we have now constructed plasmids that express p60src in Escherichia coli. Analysis of p60src produced in E. coli and selected by immunoaffinity chromatography, shows that it has the capacity to phosphorylate proteins at tyrosine residues; this activity is specifically inhibited by anti-p60src IgG. Extracts from E. coli carrying identical plasmids but lacking the src gene yield no detectable enzyme activity. These data, taken with those previously published 9,10,17, lead to the conclusion that the RSV src gene encodes a protein kinase.

Bacteria carrying recombinant molecular clones were radiolabelled in culture with 35SO4- and the cellular extracts subjected to immunoaffinity column chromatography as described in Fig. 1 legend. The presence of p60 among the proteins eluted from the columns was confirmed by phosphorylation of the preparations in vitro with the catalytic subunit of the cyclic AMP-dependent protein kinase (CAT), a previously characterized post-translational modification of pp60src (ref. 18). As shown in Fig. 1, lysates prepared from bacteria carrying a *lac-src* fusion gene in pBR325 yielded both a  $^{35}$ S-labelled protein of  $M_r$  60,000 and a protein of the same molecular weight that could be phosphorylated by CAT, whereas lysates prepared in exactly the same way from cells carrying only lac UV5 DNA in pBR325 yielded no detectable protein of a similar nature.

To determine whether p60src prepared from bacteria as described above functioned in a manner similar to pp60src prepared from eukaryotic cells, protein kinase reactions were carried out and the results are presented in Fig. 2. To reduce the possibility that any activity detected originated in the protein substrates or the IgG, these were incubated at 60 °C for 5 min before use. The results show that the extract prepared from the lac UV5-pBR325 bacteria yielded no detectable phosphotransferase activity when assayed alone or with  $\alpha$  and  $\beta$ tubulin or casein as potential substrates (Fig. 2, tracks 1, 2, 3 [lac]). In contrast, an equal quantity of extract prepared from the lac-src bacteria yielded readily demonstrable phosphorylation of  $\alpha$  and  $\beta$  tubulin and case in (Fig. 2, tracks 1, 2, 3 [lac-src]). These proteins have been shown to be efficiently phosphorylated by pp60<sup>src</sup> prepared from eukaryotic cells <sup>10,12,17</sup>. Moreover, the phosphorylation of casein was inhibited by the prior addition of anti-p60src IgG but not IgG from a non-immune rabbit (tracks 4, 5). Note that anti-p60src

Fig. 1 Polyacrylamide gel electrophoretic analysis of bacterial extracts after immunoaffinity chromatography. The lac UV5 promoter-operator 203-base pair (bp) fragment was constructed by F. Fuller and its use as a 'portable promoter' was described previously21. The DNA fragment (obtained from David L. Hare and John R. Sadler of this institution) contains an EcoRI site 65 bp from the start point of transcription and encodes nine amino acids of the *lacZ* gene. By the use of *EcoRI* linkers this promoter was fused to the 5' end of the *src* gene previously cloned from RSV-infected cells<sup>22</sup>. *E. coli* expressing p60 was detected by immunoprecipitation of <sup>35</sup>S-labelled extracts from cells containing the *lac* UV5 promoter-operator as described previously<sup>20</sup>, and one of these clones was used for the studies described here. E. coli carrying the lac UV5 promoter in pBR325 in the same orientation as in the src-containing clone served as a control for the expression of p60. DNA sequence analysis and restriction nuclease mapping of the cloned DNA indicated that the primary translation product under control of the lac promoter should contain the entire src gene product plus 11 additional amino acids at the NH2 terminus encoded by the lacZ gene and the linkers used to construct the plasmid. Peptide mapping of the p60 produced in E. coli supported this interpretation. Bacteria were grown in M9 minimal medium (6 g Na<sub>2</sub>HPO<sub>4</sub>, 3 g KH<sub>2</sub>PO<sub>4</sub>, 0.5 g NaCl, 1 g NH<sub>4</sub>Cl per 1) containing 0.8% glucose, 0.4% casamino acids, 2 μg ml<sup>-1</sup> thiamine, 40 μM MgSO<sub>4</sub>, 0.1 mM CaCl<sub>2</sub>, 1 mM isopropyl-β-D-thiogalactopyranoside and 2.5 μCi ml<sup>-1</sup> H<sub>2</sub><sup>35</sup>SO<sub>4</sub> (NEN) to an A<sub>550</sub> of 1.5, collected by centrifugation, washed once in phosphate-buffered saline and frozen quickly in liquid nitrogen. Frozen pellets corresponding to about 11 of cells were prepared for immunoaffinity chromatography by suspension in 14 ml of 10 mM Tris, 20% sucrose and 1.5 mg ml<sup>-1</sup> lysozyme. After 5 min at 4 °C DNase was added to a final concentration of  $60 \mu g ml^{-1}$  and incubation continued at 4 °C for another 5 min. The lysate was brought to a final volume of 20 ml with detergent-containing buffer at a final concentration of 1% NP40, 0.5% sodium deoxycholate, 150 mM NaCl, 5 mM dithiothreitol, 10 mM Tris pH 7.2. Lysates were clarified at 10,000g for 30 min; the protein concentration at this point was about 10 mg ml<sup>-1</sup>. The 10,000g supernatant was subjected to immunoaffinity chromatography as described previously<sup>9</sup>. Briefly, serum from a tumour-bearing rabbit selected to immunoprecipitate p60s<sup>rc</sup> encoded by the Prague A strain of RSV (the strain of the original source of the DNA) was used to prepare IgG and, subsequently, an immunoaffinity matrix at a concentration of 7 mg IgG per ml of gel. About 140 mg of protein was applied to a 6-ml column and washed as described previously except that the RIPA wash was omitted and the protein adsorbed to the column was eluted with 0.75 M KSCN. The elution of protein was monitored by liquid scintillation spectrometry of a sample of each fraction and the peak fractions were immediately dialysed against 50% glycerol containing 1 mM EDTA, 20 mM phosphate pH 7.2 and 5 mM

dithiothreitol followed by dialysis against 10% glycerol and again 50% glycerol in the same buffer to achieve about a 10-fold concentration of protein. Quantitation of the protein yield is not significant because the immunoaffinity columns are overloaded in the conditions used here. Polyacrylamide gel electrophoresis was carried out as described previously.  $^{35}$ S-labelled proteins were visualized by fluorography $^{23}$  and  $^{32}$ P-labelled proteins by autoradiography with the aid of Dupont Lightning Plus intensifying screens. Left panel: Proteins purified by immunoaffinity chromatography of lysates prepared from bacteria labelled in culture with  $^{35}$ SO $_{4}^{2}$ . Track 1, lac pBR325; 2, lac-src pBR325. Right panel: The preparations depicted in the left panel were incubated with CAT in the presence of 5 mM MgCl<sub>2</sub> and 1  $\mu$ M [ $\gamma$ - $^{32}$ P]ATP before analysis. Track 1, lac pBR325; 2, lac-src pBR325. The catalytic subunit of cyclic AMP-dependent protein kinase (CAT) was purified as described  $^{24}$  and was a gift of James L. Maller.

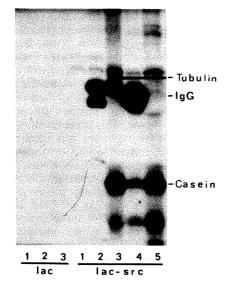

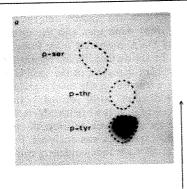

Fig. 2 Phosphorylation of various proteins by p60<sup>src</sup> partially purified from  $E.\ coli.\ 10\ \mu I\ (10\ ng)$  of the preparations described in Fig. 1 were incubated at room temperature for 10 min with the indicated additions in a total volume of 25 μl. MgCl<sub>2</sub> and  $[\gamma^{-32}P]$ ATP  $(1,000-6,000\ Ci\ mmol^{-1})$  were added to a final concentration of 5 mM and 1 μM, respectively, and incubation was continued for 30 min at room temperature. Proteins were then resolved by polyacrylamide gel electrophoresis and autoradiography. Left side (lac): Track 1, lac pBR325 alone; 2, plus  $\alpha$  and  $\beta$  tubulin; 3, plus casein. Right side (lac-src): Track 1, lac-src pBR325 alone; 2, plus  $\alpha$  and  $\beta$  tubulin; 3 plus casein; 4, plus casein and anti-p60s<sup>src</sup> IgG; 5, plus casein and non-immune IgG. Casein was present at 1 mg ml<sup>-1</sup>, the IgGs at 350 μg ml<sup>-1</sup> and tubulin at  $100\ \mu$ g ml<sup>-1</sup>. Tubulin .was prepared from rabbit brain as described previously<sup>25</sup> and was heated at 80 °C for 5 min before use.

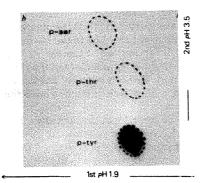

IgG is phosphorylated in the reaction, as is the case when pp60<sup>src</sup> from eukaryotic cells is similarly analysed<sup>9,10</sup>.

The protein kinase activity associated with pp60<sup>src</sup> purified from eukaryotic cells is specific for tyrosine residues in IgG<sup>11</sup> and several other protein substrates <sup>12,17</sup>. To establish further the relationship between the activity described above and that previously characterized, phosphoamino acid analysis was carried out on the products shown in Fig. 2. As seen in Fig. 3, the major amino acid phosphorylated in  $\alpha$  and  $\beta$  tubulin and in casein was tyrosine.

We describe here our preliminary characterization of the functional activity of the RSV src gene product expressed in E. coli and show that it has the capacity to phosphorylate tyrosine residues in protein substrates. Moreover, the phosphotransferase activity is inhibited by anti-p60src IgG but not non-immune IgG and results in the phosphorylation of antip60<sup>src</sup> IgG. These three characteristics, (1) immune IgG phosphorylation, (2) tyrosine specificity and (3) specific inhibition of the phosphorylation of exogenous substrates, all demonstrate the src-gene-specific nature of the enzymatic activity observed. No protein kinase activity is detectable in immunoaffinity purified preparations from identical amounts of bacteria that lack the src gene. Although the fusion protein studied here contains 11 additional amino acids (see Fig. 1 legend), we had anticipated that small changes at the amino terminus of p60src would not seriously interfere with its function because p60src shows a remarkable plasticity at the NH<sub>2</sub> terminus while still functioning to transform cells. This is most dramatically shown in studies of RSV recovered after passage of virus with partial src gene deletions through chickens, which show that the recovered viruses encode src gene products that may be 2-3,000 daltons longer or shorter at their NH2 termini but that still result in cell transformation and tumour formation19

The expression of the  $p60^{src}$ -specific protein kinase activity in  $E.\ coli$  strongly supports the previous conclusion that the enzymatic activity observed in preparations from eukaryotic cells is actually encoded in the src gene and is not the result of the co-purification of one of the many cell-encoded protein kinases expressed in RSV-infected cells. Although we estimate that the  $p60^{src}$  from  $E.\ coli$  is about 10% as active as a similar preparation from eukaryotic cells, the results described here should be regarded as qualitative because we anticipate that modification by phosphorylation with, for example, purified

**Fig. 3** Phosphoamino acid analysis of  $\alpha$  and  $\beta$  tubulin and casein phosphorylated by p60<sup>src</sup>. Phosphorylated  $\alpha$  and  $\beta$  tubulin and casein, as shown in Fig. 2, right, tracks 2 and 3, were eluted from a preparative gel, precipitated and hydrolysed in 6 M HCl at 100 °C for 3 h. The phosphoamino acids were resolved by two-dimensional electrophoresis at pH 1.9 and 3.5 and visualized by autoradiography as described previously12 Authentic phosphoamino acids were included in the sample and were visualized by ninhydrin staining. a,  $\alpha$  and  $\beta$  tubulin; b, casein.

CAT may affect the activity. The evolutionary distance of E. coli from the normal RSV hosts makes it unlikely that they would harbour protein kinases such as the cyclic AMP-dependent protein kinase known to modify p $60^{\text{src}}$  (ref. 18). We have not detected phosphorylation of p $60^{\text{src}}$  in *E. coli*<sup>20</sup> and, if additional experiments confirm that the protein is unphosphorylated in E. coli, p60src prepared in this manner should prove useful for the study of the effect of phosphorylation on its function. Similarly, analysis of the src gene product produced in E. coli should be useful for the resolution of the issue of whether pp60src has the capacity to phosphorylate itself during in vitro phosphotransferase reactions, an activity previously demonstrated in this laboratory<sup>10</sup> but not observed by others<sup>17</sup>. Additional studies will permit quantitative comparisons of the enzymatic activity of p60src of prokaryotic and eukaryotic origin.

We thank J. Gordon Foulkes for helpful discussions, J. B. Varner and E. Erikson for advice and help with these experiments, and John R. Sadler and David L. Hare for their advice on molecular cloning. This research was supported by NIH grant CA-21117, an award from the ABC Research Foundation and, in part, by NIH grant CA-15823 and by a gift from the R.J. Reynolds Industries, Inc. to the Department of Pathology. T.M.G. was supported by NIH PHS grant 5T32-AI 07209.

#### Propagation of foreign DNA in plants using cauliflower mosaic virus as vector

Bruno Gronenborn, Richard C. Gardner\*, Sabine Schaefer & Robert J. Shepherd\*

Institut für Genetik der Universität zu Köln, Weyertal 121, 5000 Köln 41, FRG

\* Department of Plant Pathology, University of California, Davis, California 95616, USA

Cauliflower mosaic virus (CaMV) is the best analysed member of the caulimoviruses, a group of small isometric plant viruses that contain a circular double-stranded genome (for review see ref. 1). As most plant viruses have an RNA rather than a DNA genome, caulimoviruses have attracted considerable interest due to their potential use as genetic vectors for plants. DNA purified from CaMV particles can infect plants and cause virus production when rubbed over the surface of susceptible leaves2. Moreover, the entire chromosome of several CaMV strains can be propagated through bacterial hosts by plasmid and phage  $\lambda$ vectors and has been used successfully to infect plants' Recently, Howell et al.5 reported the insertion of an 8-base pair (bp) EcoRI linker molecule into the large 'intergenic' region of cloned CaMV strain CM 4-184 DNA without impairment of infectivity. Here we report the successful propagation of foreign DNA in plants using cauliflower mosaic virus as vector. We find that the size of foreign DNA that can be successfully propagated

through virus particles has an upper limit of  $\sim 250$  base pairs. The nucleotide sequence of CaMV<sup>6.7</sup> suggests that there are extensive regions of the genome which encode protein. To insert new DNA, however, it is necessary to identify non-coding or dispensable regions where insertions will not interfere with essential functions. To identify such regions, we selected a segment of DNA which specifies a phenotype in Escherichia coli that is easily detected and selected, and which is sufficiently small so as not to exceed a possible limitation on packaging capacity of the virion. This marker DNA was then inserted into the CaMV genome cloned in an E. coli plasmid vector.

The E. coli marker chosen for these trial insertions was a 65-bp fragment derived from the lac promoter-operator region<sup>8</sup>. In a multicopy plasmid, this *lac* operator fragment leads to a lac constitutive phenotype in a suitable host due to titration of lac repressor9. We provided the fragment with an asymmetrically positioned EcoRI restriction site and added synthetic XhoI linker molecules to its ends<sup>10</sup>. XhoI linkers were chosen because the position of a naturally occurring XhoI site on the chromosome of CaMV strain 1841 is covered by a deletion in the variant strain CM 4-184 (refs 11, 12), indicating a nonessential region of the genome. The lac operator with XhoI ends could be inserted easily to test this hypothesis. As an acceptor molecule we used DNA of plasmid pCaMV10, a derivative of pBR322 carrying the complete genome of CaMV strain 1841 (refs 4, 12). The structure and orientation of two different *lac* operator inserts are given in Fig. 1.

To test whether a CaMV genome containing such inserts is infectious, the viral DNA was released from the plasmid vector by cleavage with SalI restriction endonuclease and used to infect leaves of 'Just Right' turnip plants (Brassica campestris L.). About 200 ng of DNA per leaf were sufficient to cause 2-30 local lesions on mechanically inoculated leaves and led in all cases to symptoms typical of systemic infection<sup>13</sup>. The

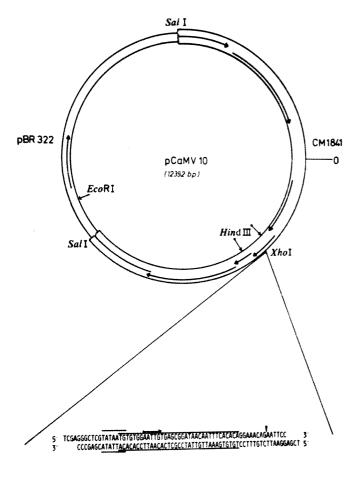

Fig. 1 Structure and orientation of the 1841-EOP2 lac operator insert at the unique XhoI site of the CaMV 1841 hybrid plasmid pCaMV10. A 55-bp HpaII-EcoRI restriction fragment from the lac UV5 promoter-operator region of E. coli in plasmid pUR108-1 (ref. 8 and U. Rüther, unpublished results) was given flush ends by incubation with E. coli Pol I Klenow fragment (Boehringer) in the presence of dATP and dTTP<sup>17</sup>. After purification by electrophoresis through an 8% polyacrylamide gel, 1 pmol of fragment was ligated to 50 pmol of Xhol linker molecules (Collaborative Research)<sup>10</sup>. This step restores the EcoRI restriction site at the promoter distal end of the fragment. Xhol restriction endonuclease digestion (restriction enzymes from New England Biolabs, Boehringer or BRL) was used to cleave off superfluous linkers and a second 8% polyacrylamide gel was used to prepare the now Xhol-ended fragment. The purified fragment was ligated to pCaMV10 DNA linearized by XhoI. Hybrid molecules were identified after transformation of E. coli CSH 51 (ref. 18) and selection of ampicillin esistant bacteria on plates containing ampicillin (50 µg ml<sup>-1</sup>) and 5-bromo-4-chloro-indolyl-B-D-galactoside (40 µg ml<sup>-1</sup>). lac constitutive bacteria produce blue colonies in these conditions<sup>18</sup>. Two different isolates were analysed further; these carry the *lac* operator in both orientations in the CaMV genome. In addition, pCaMV10-EOP1 has lost one terminal nucleotide pair at the HpaII end of the lac operator. The six open reading frames of CaMV are indicated by arrows, starting in a clockwise direction from the zero point of the map. The orientation of pBR322 relative to CaMV DNA is indicated by its unique EcoRI site and the reading frame of the B-lactamase gene. The lac operator insert of pCaMV10-EOP2 is enlarged at the bottom. The Pribnow box homology and the operator sequence are underlined. The arrow pointing to the right indicates the transcription start point in  $E.\ coli$ . The additional EcoRI site is indicated by  $\nabla$ . pCaMV10-EOP1 carries the lac operator in the opposite orientation and lacks one GC pair at the former HpaII end of the fragment.

appearance of symptoms was slightly delayed compared with infection by the parent molecules and the disease symptoms were milder. Viral DNA prepared from infected plants was analysed <sup>14</sup>. Figure 2a shows that the lac operator fragment can be recovered after XhoI digestion of the viral DNA. To determine whether only a fraction of the viral population contained the insert, four individual local lesions induced by DNA containing both types of inserts were transferred to several new plants. After systemic symptoms developed, viral DNA from each of the individual transfers was analysed. Figure 2b shows that the offspring of all eight independently transferred lesions carried the lac operator insert.

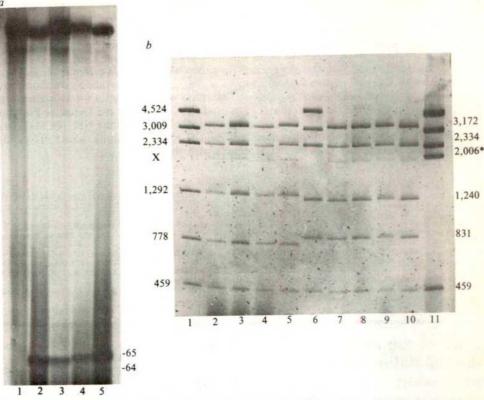

To determine whether the inserts were copied correctly during viral DNA replication we subcloned in plasmid pBR322 a HindIII restriction fragment containing the lac operator inserts at the XhoI site (Fig. 1) from either passaged CaMV DNA or from the parent plasmid used to infect the plants. DNA of these subclones was sequenced according to the Maxam-Gilbert procedure<sup>15</sup>. Figure 3 shows an example of the sequence comparison. No changes in the sequence of the two lac operator regions were detected. Regions adjacent to the site of insertion showed no sequence alteration compared with the pCaMV10 parent DNA sequence.

The stability of the inserts was checked after three successive transfers of virus derived from systemically infected tissue. All eight independent insert lines still contained the *lac* operator fragment. Some revertants occurred in the CaMV-EOP1 progeny, as indicated by the appearance of additional minor bands in the *EcoRI* restriction pattern. With CaMV-EOP2 (opposite orientation) no minor bands due to revertants could be detected. However, after five successive transfers and extended growth of the plants (2 months) the *lac* insert in both orientations was lost. In these conditions rare revertants seem to have a selective advantage over the insertion mutants which have slightly delayed growth.

To determine the maximum insertion capacity at the Xhol site, we inserted fragments of 256, 531 and 1,200 bp, respectively. The 256- and 531-bp fragments were derived from phage A DNA cleaved with SalI and XhoI (sites 44, 45 and 46 of a 1981 \( \lambda \) map update, F. R. Blattner et al., personal communication). The 1,200-bp fragment, a SalI segment of pUC5 containing the kanamycin resistance gene of Tn903 (Vieria and J. Messing, unpublished results), carries PstI sites adjacent to its SalI ends, with the kanamycin resistance gene inserted between the PstI sites by G·C homopolymer tails. Infectivity assays using CaMV DNA containing these inserts were performed as described above. After development of systemic symptoms, viral DNA was prepared from infected leaves and analysed. Figure 4 shows the EcoRI digestion pattern of CaMV DNA derived from the 256- and 531-bp insertions; only the former was propagated stably. Insertion of 531 bp gave rise to three different deletion mutants in the region of insertion. These infections were apparent in plants only after a prolonged period: 5-6 weeks after inoculation as opposed to 2 weeks normally required for systemic development. In addition, attempts to recover infectious CaMV DNA molecules containing the 1,200bp fragment were unsuccessful. Analysis of the viral DNA from plants that developed symptoms showed that the inserted fragment was lost, perhaps by recombination in the homopolymer tails as most of the isolates gained at least one additional PstI site at the insertion point.

Thus, we have provided evidence for a non-essential region in the CaMV genome. Insertion of foreign DNA from two different sources into an XhoI restriction site whithin this region does not interfere with the infectivity of the viral DNA nor with virus production. However, the stability of the 256-bp  $\lambda$  DNA insert in a systematic survey has not been compared with that of the lac EOP inserts. The instability of the 64/65-bp lac promoter-operator inserts could be due to some peculiarity of the DNA sequence itself. Note for example the similarity of the lac UV5 Pribnow box to the 'TATAA' initiation signal sequence for RNA polymerase II in eukaryotes<sup>16</sup>. Whether the

Fig. 2 a, Viral DNA was prepared from plants that had been infected with SalIcut DNA of pCaMV10 (lane 1), pCaMV10-EOP1 (lane 3) and pCaMV10-EOP2 (lane 4). After cleavage by XhoI restriction endonuclease and labelling with  $[\alpha^{-3^2}P]dATP$  by polymerase I (Boehringer), the DNA was electrophoresed on a 10% polyacrylamide gel. Plasmid DNA pCaMV10-EOP1 (lane pCaMV10-EOP2 (lane 5) was treated in the same way. The 64-bp operator frag-ment of -EOP1 can be distinguished from 65-bp fragment of -EOP2, as indicated at the right-hand side. b, EcoRI restriction pattern of viral DNA derived from eight independent local lesion isolates of CaMV-1841-EOP1 and EOP2 that had been transferred to a set of new plants. Lanes 1, 6 and 11 contain plasmid from pCaMV10-EOP1, pCaMV10-EOP2 pCaMV10. and respectively. Lanes 2-5 contain DNA from four different isolates of CaMV1841-EOP1; lanes 7-10, DNA of four independent isolates of CaMV1841-EOP2. The EcoRI fragment that has been modified by the insertions is indicated by \*. The size of the fragments is given in base pairs. The introduction of the lac operator insert into the 2,006-bp EcoRI fragment also introduces an additional EcoRI restriction site and gives rise to two new fragments, the sizes of which (1,292 and 778 bp as opposed to 1,240 and 831 bp)

vary depending on the orientation of the insert. X indicates a submolar fragment present in all *EcoRI* digests of CaMV DNA<sup>7</sup>. The 4,524- and 3,009-bp fragments are 'hybrid' fragments containing CaMV and pBR322 DNA, their CaMV moiety is part of the 3,172- and 2,334-bp fragments of the viral DNA.

transcription patterns of CaMV 1841-EOP1 or 1841-EOP2 differ from that of CaMV 1841 has not been determined.

A packaging limitation of CaMV particles for additional DNA seems to restrict larger inserts—an additional 531 bp could not be successfully propagated in similar experiments. Thus there seems to be an upper limit for additional DNA of 256–531 bp. Recombinant molecules having large insertions in the CaMV genome may replicate, as a whole, only in those cells which become initially infected after inoculation. Perhaps encapsidation occurs only after sufficiently small deletions have arisen and may be a prerequisite for cell-to-cell movement and

COTAG COTAG

Fig. 3 Sequence comparison of the lac operator insert before and after passage through the plants. The respective HindIII restriction fragments (see Fig. 1) were subcloned in pBR322 (ref. 19). DNA of the hybrid plasmids was cleaved by EcoRI, labelled either with  $[\gamma^{-32}P]ATP$  (Amersham) and T4 polynucleotide kinase (Boehringer) or by Pol I Klenow fragment plus [α-32P]dATP to label the opposite strand. After cleavage with HindIII and preparation of the fragments on 6% polyacrylamide gels, the DNA sequence of the inserts was determined as described elsewhere 15. The figure shows an 8% sequencing gel of CaMV-EOP1 DNA (after passage) labelled with  $[\alpha^{-32}P]$ dATP (a)and pCaMV10-EOP1 DNA before passage through the plants (b). The readable sequence starts with 3' AACAAT 5' in the middle of the lac operator (see Fig. 1, upper strand).

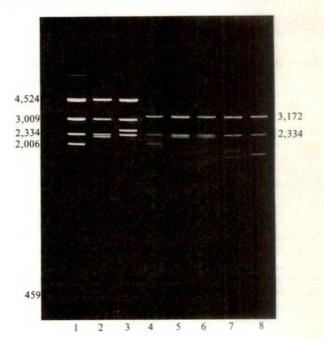

Fig. 4 EcoRI restriction pattern of Λ DNA insertions in CaMV1841. Lane 1, EcoRI-cleaved plasmid DNA of pCaMV10; lanes 2 and 3, pCaMV10 containing a 256-and a 531-bp insert of Λ DNA, respectively. The insertions at the XhoI site cause differences in mobility of the former 2,006-bp fragment. Lanes 4-8 contain viral DNA isolated from individual plants that showed symptoms after inoculation with the three plasmid DNAs cut by SalI. Lane 4 shows the wild-type CaMV1841 EcoRI restriction pattern. The mobility of the EcoRI fragment that contains the 256-bp insert seems identical to that of the parent plasmid (lanes 5 and 6). In contrast, the 531-bp insert produced three different deletions, each of which rendered the fragment carrying the insert smaller than the wild-type 2,006-bp fragment (lanes 7 and 8). Only the largest of these new fragments (lane 7) still contains sequences that hybridize to λ DNA (data not shown).

systemic development in the plant. Further experiments with a 363-bp insertion at the XhoI site of pCaMV10 support this assumption as there is an 'eclipse period' of >2 months before the plants start to develop symptoms of virus infection. Analysis of the viral DNA reveals that deletions occur which include part of the DNA inserted and part of reading frame II on the CaMV chromosome (B.G. et al., in preparation).

As insertion of foreign DNA in the XhoI site interferes with expression of the assumed reading frame II<sup>3,4</sup>, its product might be non-essential. Alternatively, this region may not code for any protein at all. The finding that the deletion in CM4-184 eliminates almost the entire coding region II agrees with these results12.

Insertion of bacterial DNA has been useful in probing the genome of CaMV. We are now investigating whether there are other regions suitable for insertions and whether inserts of different kinds can be used to express new proteins in plants using CaMV as vector.

#### Role of the *nifA* gene product in the regulation of nif expression in Klebsiella pneumoniae

V. Buchanan-Wollaston, M. C. Cannon, J. L. Beynon & F. C. Cannon

ARC Unit of Nitrogen Fixation, University of Sussex, Brighton BN1 9RQ, UK

The nitrogen fixation (nif) gene cluster of Klebsiella pneumoniae is linked to his, consists of at least 17 genes arranged in seven or eight operons1-4 (Fig. 1), and its expression is inhibited by oxygen (O2) and fixed nitrogen (N) including ammonia, nitrate and amino acids (see ref. 5 for review). Previous studies have suggested that the nifA and nifL gene products respectively activate 6-8 and repress 9,10 nif expression. There has also been evidence, from mutants that express nif constitutively in the presence of fixed N, that regulation by fixed N involves the gln (glutamine synthetase) genes<sup>11,12</sup>, and that their products act at the promoter of the nifLA operon<sup>13,14</sup>. We have recently shown by direct measurement of transcription in vivo that the nifA and nifL gene products are, respectively, an activator and repressor of nif transcription initiation from all nif promoters except that of the nifLA operon15. We now report experiments aimed at clarifying the role of the nifA product and the interaction of the nifLA operon and gln genes in controlling nif expression. Having constructed plasmids that constitutively express the nifA gene and investigated nif expression in a variety of K. pneumoniae strains transformed by such plasmids, we show that, in the absence of nifL protein, nifA expression is sufficient to activate nif expression, even in the presence of fixed N and O2. gln-mediated regulation of nif by fixed N exerts its effect by controlling nifLA expression. We have also confirmed that the nifA protein is temperature sensitive, thus explaining the absence of nif expression at 37 ° C. Our results provide a strategy by which the constitutive expression of nif in the presence of fixed N and O2 is stabilized and suggest a model for nif transcriptional regulation.

To investigate the regulation of nif expression by fixed N and O<sub>2</sub> and to clarify the role of the nifA product, we have used a variety of K. pneumoniae strains transformed with plasmids permitting constitutive expression of the nifA gene. The gene was cloned as a SalI fragment (which also contained part of the 3' end of the nifL gene) in the multicopy vectors pACYC184 and pACYC177 (ref. 16). The fragment was inserted into the SalI

site of pACYC184 in both orientations, giving pMC71A and pMC71B; in pMC71A nifA was expressed from the promoter of the tetracycline resistance gene (Tc<sup>r</sup>). Insertion into the XhoI site of pACYC177 in both orientations gave pMC73A and pMC73B; expression of nifA in pMC73A was from the promoter of the kanamycin resistance gene (Km<sup>r</sup>).

Table 1 Nitrogenase activities of K. pneumoniae strains with and without nifA plasmids

Strain	Nitrogenase activity as % of that in derepressed UNF928 -NH <sup>+</sup> +NH <sup>+</sup>		
UNF928 (nif wild-type strain)	100	0.005	
UNF714 (nifA)	0	0	
714 (pMC71A)	97	15	
714 (pMC71B)	7	0.1	
714 (pMC73A)	230	27	
714 (pMC73B)	0.1	0.1	
UNF1780 (gln A100 → Nif <sup>-</sup> )	0.05	0.075	
1780 (pMC71A)	328	88	
1780 (pMC71B)	257	1	
1780 (pMC73A)	174	80	
1780 (pMC73B)	0.005	0.005	
UNF1827 $(gln A201 \rightarrow Nif^-)$	6	0.005	
1827 (pMC71A)	276	86	
1827 (pMC71B)	122	0.07	
1827 (pMC73A)	279	70	
1827 (pMC73B)	0.2	0	
UNF1829 $(glnG36 \rightarrow Nif^-)$	0.1	0	
1829 (pMC71A)	284	22	
1829 (pMC71B)	226	0.03	
1829 (pMC73A)	125	22	
1829 (pMC73B)	0.06	0.07	

Overnight cultures (4 ml) were grown anaerobically in bijoux bottles in NFDM<sup>22</sup> containing 25 μg ml<sup>-1</sup> histidine and 100 μg ml<sup>-1</sup> serine (UNF928, UNF714 strains) or 100 μg ml<sup>-1</sup> glutamine (UNF1780, UNF1827, UNF1829 strains) (-NH<sub>4</sub><sup>+</sup>). Serine was omitted in NH<sub>4</sub><sup>+</sup>grown cultures (+NH<sub>4</sub>) which contained 10 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>. Strains carrying pMC71A and B and pMC73A and B were selected with 25 µg ml<sup>-1</sup> chloramphenicol and 200 µg ml<sup>-1</sup> carbenicillin, respectively. Nitrogenase activity was measured by acetylene reduction as described in ref. 22. Relevant genotypes are: K. pneumoniae strains, UNF928 (hisD hsdR recA), UNF714 (hisD nifA hsdR recA), UNF1780 (hisD glnA100 hsdR recA), UNF1827 (glnA201hsdRrecA) and UNF1829 (glnG36hisD,hsdRrecA). UNF1780, UNF1827 UNF1829 do not express nifA or nifL, even in the absence of NH<sub>4</sub>, because they lack the necessary gln-mediated positive control.

**Table 2**  $\beta$ -galactosidase expression from the *nifH* promoter in strains with and without *nifA* plasmids

S	train	β- -N	galactos H <sup>+</sup>	idase uni +N	
1. UNF921			3		3

	(pMC71B)	7	16	1	25
4. UNF931	(pJB31)	2,2	200		2
5. MC1061	(pJB31)		3		2
6. MC1061	(pJB31) (pMC71A)	6,0	)27	4,2	46
		-N	$H_4^+$	+N	$H_4^+$
		+O <sub>2</sub>	$\overline{-O_2}$	+O <sub>2</sub>	$-O_2$
7. UNF921		3	6	2	3
8. UNF921	(pMC71A)	2,250	2,160	1,570	3,000
9. UNF921	(pRD1)	22	2,200	. 8	6

Overnight cultures (4 ml) of strains 1-6 were grown anaerobically in bijoux bottles in NFDM<sup>22</sup> containing 25  $\mu$ g ml<sup>-1</sup> histidine except for UNF921 (pRD1), 100  $\mu$ g ml<sup>-1</sup> serine (-NH<sub>4</sub>) or 10 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> instead of serine (+NH<sub>4</sub>). Overnight cultures (10 ml) of strains 7-9 were grown in the same two media under a constant stream of air (+O<sub>2</sub>) or N<sub>2</sub>(-O<sub>2</sub>) in 100-ml conical flasks which were vigorously shaken. All cultures were grown at 28 °C.  $\beta$ -galactosidase activities were measured as described in ref. 8. Relevant genotypes are: *K. pneumoniae* strains, UNF921 ( $lazZ:nifH \nabla (his-nifH)recA hsdR$ ), UNF931 (hisD lac recA hsdR) and *E. coli*, MC1061 ( $hsdR \triangle (lacIPOZY)X74$ ). Plasmid pMC71A and B carry Cm<sup>7</sup> and nifA genes, pJB31 carries Ap<sup>7</sup> and lacZ:nifH genes and pRD1 is a conjugative plasmid carrying Ap<sup>7</sup> Tc<sup>7</sup> Km<sup>7</sup> his and nif genes. Details of pJB31 construction will be published elsewhere.

Expression of *nifA* from these plasmids was checked in a NifA<sup>-</sup> strain UNF714. The results in Table 1 show that pMC71A and pMC73A both complemented the *nifA* mutation in UNF714. The low level of activity obtained with pMC71B was probably due to expression of *nifA* from an unidentified promoter on pACYC184, because a significant level was not obtained with pMC73B, indicating that no transcription initiation occurs between *nifL* and *nifA*.

Table 1 lists the nitrogenase activities of several different K. pneumoniae strains with and without the nifA plasmids and in the presence and absence of NH<sub>4</sub>. Nitrogenase activity in the nif wild-type strain UNF928 is repressed in the presence of 10 mM NH<sub>4</sub>. However, strain UNF714, when restored to Nif<sup>+</sup> by pMC71A or pMC73A, shows 15-30% constitutive nitrogenase activity (activity in the presence of NH<sub>4</sub> as a percentage of that in the absence of NH<sub>4</sub>). Constitutive nif expression in the presence of NH<sub>4</sub> was also examined by measuring β-galactosidase activity in a strain (UNF921) with a nifH::lacZ fusion (Table 2). In this strain the *lacZ* gene is fused to the *nifH* promoter and *his-nifH* is deleted (M. Merrick, unpublished). Strain UNF921 carrying pMC71A shows 100% constitutive  $\beta$ -galactosidase expression from the *nifH* promoter. The difference in degree of constitutive expression at the transcriptional ( $\beta$ -galactosidase activity) and nitrogenase activity levels may be due to a physiological effect on nitrogenase activity in an NH<sub>4</sub><sup>+</sup>-grown culture. The effect of O<sub>2</sub> on nif expression could be examined in UNF921 (pMC71A); nitrogenase activity could not be used because the enzyme is inactivated by  $O_2$ . The results (Table 2) show that  $\beta$ -galactosidase expression was 70-100% constitutive in UNF921 (pMC71A) grown in the presence of O<sub>2</sub> with and without NH<sub>4</sub>.

Fig. 1 Map of K. pneumoniae nif genes<sup>1-4</sup>. The arrows indicate nif operons and their directions of transcription. The SalI restriction fragment used in the construction of nifA clones is denoted by S-S. Kb, kilobases.

Thus these results show that nifA protein is active in the presence of fixed N and  $O_2$ , and that in the absence of nifL protein only the nifLA operon is regulated by fixed N or  $O_2$ .

To examine the possibility that the nifA protein is the only nif gene product required for transcriptional activation of the nifH promoter, we constructed a small, multicopy plasmid, pJB31, carrying a translational nifH::lacZ fusion. nifH and lacZ were fused by Bal31 digestion from codons 147 and 8 of the respective genes followed by blunt-end ligation and selection of clones which had  $\beta$ -galactosidase activity. The results in Table 2 show that lac was not expressed from pJB31 in an Escherichia coli strain, MC1061, while in the Nif+ strain UNF931 lac expression from pJB31 was under normal nif regulation. When pMC71A was also present in MC1061, lac was expressed at a high level from pJB31 even in the presence of NH4. Thus, the only nif gene product required for activation of the nifH promoter is that of nifA. SDS-polyacrylamide gel electrophoresis of pulselabelled extracts from UNF921 (in which his-nifH is deleted) and UNF921 (pMC71A) also indicated that the nifA protein was the only nif gene product required for expression from the nifJ promoter.

The constitutive expression of nif in UNF714 carrying pMC71A or pMC73A suggested that gln-mediated regulation of nif expression acted only at the promoter of the nifLA operon. To test this hypothesis we investigated the effect of the nifA plasmids on nif expression in three gln mutants, which normally do not express nif, presumably because a gln protein regulates transcription of the nifLA operon. The results (Table 1) show that the expression of nif was independent of gln when plasmids that constitutively expressed nifA were present in these mutants, indicating that only the nifLA promoter was directly regulated by the gln system.

The plasmid pMC71B restored higher nitrogenase activity to the Gln strains than to UNF714 (Table 1), perhaps due to the absence of nifL expression in the gln mutants. We have found that the nifL protein repressed nif transcription<sup>15</sup> and it is possible that in its absence less nifA protein is required to give a high level of nif expression. A result consistent with this observation is that a nifL mutant derepressed at a faster rate and gave

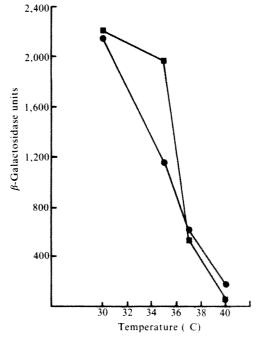

Fig. 2 Effect of temperature on *nif* expression in UNF921 (pMC71A) ( $\blacksquare$ ) and UNF921 (pRD1) ( $\blacksquare$ ). Cultures (10 ml) in 25-ml conical flasks were grown anaerobically in NFDM containing serine (100  $\mu$ g ml<sup>-1</sup>)<sup>22</sup>. UNF921 (pMC71A) cultures also contained histidine (25  $\mu$ g ml<sup>-1</sup>) and chloramphenicol (25  $\mu$ g ml<sup>-1</sup>). After overnight growth at four different temperatures  $\beta$ -galactosidase activities were measured as previously described<sup>8</sup>.

a higher level of nitrogenase activity than the wild-type (ref. 17 and M.C.C., S. Hill, E. Kavanagh and F.C.C., in preparation). The repression of nif by NH<sub>4</sub> in the gln mutants carrying pMC71B is probably due to a blocking of nifA expression by vigorous transcription from the Tcr promoter in the opposite direction. We have found that transcription from the Tc promoter blocked transcription from the opposite direction in a similar promoter arrangement<sup>15</sup>.

Nitrogenase from K. pneumoniae is active at 37 °C but nif is not expressed at this temperature 18. There is evidence that this temperature sensitivity is mediated by the nifL and/or A gene products<sup>17,19</sup>. We therefore examined the effect of temperature on the activity of nifA protein by comparing  $\beta$ -galactosidase expression in the nifH::lacZ fusion strains UNF921 (pMC71A) and UNF921 (pRD1) at different temperatures. Strains carrying pACYC184 grow in the presence of Tc at the temperatures used and this shows that transcription initiation from the Tc promoter on pMC71A is not temperature sensitive. Figure 2 shows that sβ-galactosidase activity decreased in both strains with an increase in temperature. As nifA protein is constitutively synthesized from the Tcr promoter in UNF921 (pMC71A) and no nifL protein is present, this result shows that the nifA protein is temperature sensitive. A similar result was obtained with a plasmid on which nifA alone was expressed from the nifLA promoter, which is known not to be temperature sensitive  $^{17,19}$ . The *nifA* protein has some activity at 37 °C and the observation that nifL mutants express nif at 37°C17 is probably due to a lower requirement for nifA protein in the absence of a functional *nifL* protein (see above).

Our results show that *nif* expression can be switched on

constitutively by inactivating nifL and fusing nifA to a constitutive promoter. These and other recent results provide strong evidence for the following model of nif transcriptional regulation. In nif derepressing conditions a gln protein activates transcription of the nifLA operon. The nifA protein then activates transcription of the other nif operons while the nifL protein is maintained in an inactive form by interaction with a regulatory metabolite. A probable candidate for this role is the purine nucleotide ppGpp which has an important regulatory role in conditions of N starvation<sup>20,21</sup>. When fixed N or O<sub>2</sub> is added to a derepressed culture the level of the regulatory metabolite is decreased and the nifL protein becomes a repressor of transcription at the promoters of all the nif operons except that of nifLA. A rapid decrease in the level of ppGpp in these conditions would lead to the transition of RNA polymerase to a different structural form<sup>21</sup> which would probably be less efficient at initiating transcription from *nif* promoters. Therefore, the repressor activity of nifL protein and the altered RNA polymerase would both contribute to a rapid nif switch-off on addition of fixed N or O<sub>2</sub>. In the presence of fixed N a gln protein represses transcription from the nifLA promoter, thus concomitantly removing the nif repressor and activator. Repression of nif in cultures grown in N-rich media would therefore be maintained solely by the absence of the nifA protein.

We thank R. Dixon, G. Espin, A. Alvarez-Morales and M. Merrick for strains, S. Jenkins for assistance, S. Hill for useful discussions and the National Research Development Corporation for support.

#### cDNA sequences of human glucose 6-phosphate dehydrogenase cloned in pBR322

M. G. Persico, D. Toniolo, C. Nobile, M. D'Urso & L. Luzzatto\*

International Institute of Genetics and Biophysics, CNR, Napoli, Italy

Glucose 6-phosphate dehydrogenase (G6PD) catalyses the first reaction of the so-called oxidative pathway of glucose metabolism1. In many cells, in addition to providing pentose sugars required for nucleic acid synthesis, G6PD has a major role in providing an adequate supply of reducing power in the form of NADPH (ref. 2). The enzyme has been purified and characterized from many sources'. G6PD from mammalian cells consists of a homodimer or a homotetramer, with a subunit molecular weight of ~58,000 (ref. 4), and its structural gene is located on the X chromosome<sup>5</sup>. Genetic variation of G6PD is extensive in humans. Many variants associated with relative deficiency of enzyme activity ('G6PD(-)') are polymorphic in various populations and have probably been selected for by Plasmodium falciparum malaria<sup>6</sup>. A number of G6PD(-) variants can cause either acute or chronic haemolytic anaemia and therefore have considerable clinical importance<sup>7</sup>. We considered that a knowledge of the G6PD gene would be of interest because it may be representative of a large number of genes and could help to elucidate in detail the basis for various forms of G6PD deficiency. Here we report how G6PD cDNA sequences have been cloned starting from human mRNA in which G6PD mRNA is present at an abundance of less than  $10^{-4}$ 

Human diploid fibroblasts were grown from a primary skin explant by standard techniques<sup>8</sup>. Approximately 10<sup>9</sup> cells were used to prepare total RNA by the guanidine HCl method9. Enrichment for G6PD-specific mRNA was obtained by successive steps, consisting of oligo(dT)-cellulose chromatography and two successive sucrose gradient centrifugation runs, as will be described in detail elsewhere (D.T., M.G.P., G. Battistuzzi and L.L., in preparation). The purification was followed by a specific assay based on cell-free translation (see Fig. 1). From the enriched mRNA (Fig. 1, tracks 4, 7), cDNA was prepared using oligo(dT)-primed reverse transcriptase according to Sobel et al.  $^{10}$ , except that the concentration of oligo(dT) was 5 µg ml $^{-1}$ and that of each deoxynucleoside triphosphate was 1 mM. From this cDNA, double-stranded DNA was obtained using Escherichia coli DNA polymerase<sup>11</sup>, and after C-tailing<sup>12</sup> it was annealed to G-tailed plasmid pBR322 (ref. 13) and used to transform E. coli HB101 (ref. 14). After plating on tetracyclineagar plates, 4,750 colonies were observed, of which 3,470 were found to be ampicillin sensitive, indicating that they contained a plasmid with a double-stranded DNA insert. From an estimate of the abundance of G6PD mRNA in the reverse-transcribed preparation, we expected that 5-10 should contain G6PD sequences

The 3,470 colonies were screened by two approaches. First, RNA from cultured HeLa cells was purified as outlined in Fig. 1

# Darwin through a purple haze

A.J. Cain

THERE are already far too many books about Darwin, and most of them tell us more about their authors than their subject-matter. It would be an injustice to leave Mr Brent's book in that category without considerable qualification. It will certainly be widely read, and for many people it may be their first introduction to Charles Darwin's mental, moral and hormonal development. Mr Brent is a wellpractised writer — he has already produced three novels and, according to the dust jacket, "ten pseudonymous thrillers, a study of Hindu gurus, two narrative histories, and several biographies". When he gets down to straightforward narrative and to psychological surmise, he is in his element; and he has certainly worked over a great deal of unpublished material relating to Charles's relations with his father, his sisters and other relatives, his early flames, his wife and his numerous friends. He has also profited, as he makes clear, from a number of other studies of Darwin and Darwinism: to that extent, the book is one of the best and most up-to-date accounts of Charles Darwin as a man that one can find.

Unfortunately, it is far from satisfactory in a most predictable way; the science in it is so light-weight that yet again we have Hamlet without the Prince, a sort of Himmelfarb rediviva. When will people of only literary training (and I include philosophers and some historians) realize that to write the history of a scientist they must intuit not only into his complexes and sex life but into his science as well?

The book is obviously aimed at the general market to be created by the centenary of Charles Darwin's death, already partly excited by the anti-Darwinian rubbish recently appearing in the popular press and on television and radio. To ensure a wide acceptance, the author has decorated it freely with purple passages which do not accord well with the generally excellent style in the narrative parts. Indeed, the first page after the Introduction, beginning "The boy is sturdy, high-complexioned, with fine, chestnut-coloured hair now in some disarray" and containing the remarkable sentence "Briefly, in delighted alarm, pigeons flick to and fro against the bulbous clouds" may even put off some who would find better things later.

Much of this could be disregarded, were not the same inflation constantly used on Charles Darwin himself. His attitude towards marriage was somewhat "monstrous" (p.249), his approach to his main task was "almost inhumanly thorough" (p.281), he was capable of "an

Charles Darwin: A Man of Enlarged Curiosity. By Peter Brent. Pp.536. ISBN UK 0-434-08595-2; ISBN US 0-16-014880-2. (Heinemann, London/Harper & Row, New York: 1981.) £12.50, \$20.75.

almost frightening objectivity" (p.320); many such expressions combine to build a picture of almost a maniac. They are reinforced by numerous suggestions of duplicity (p.187), hypocrisy (p.475), eagerness to duck criticism (p.229) and so on, which make the book a God-sent mine of reference for any fundamentalist wanting to denigrate Darwin. It is true that Mr Brent, having made these remarks often qualifies them; but as Paul Hazard reminds us, so-called refutations of Spinoza served to spread his ideas, and many of Mr Brent's self-rejected suggestions have now got into print. In much of what he judges so harshly, I see little more than very human vacillations, and not infrequently early Victorian modes of expression which he has taken rather too

Mr Brent has done his best with Darwin's sex-life, in spite of a plentiful lack of material; indeed, at one point he speaks of the prurience of a biographer. His suggestions about Charles's relations with his sisters, and their over-mothering him are excellent, as is his perceptive account of his relations with his father. But when (p.263) he sees Emma as offering Charles another aspect of the same archetype, Lady of the Manor and Peasant" he himself comments that "perhaps it gives it [this strand in their relationship] a false importance even to select it for comment" and goes on immediately to emphasize it. And he just cannot resist a remark of one of Charles's female friends (p.61) regretting she was not there to meet him and "to make a beast of myself in the strawberry beds". Mr Brent gets quite excited about those strawberry beds, and his comment "One sees them [Fanny and Charles] at their languid orgy, half children, half adults" etc. etc. is worthy of Cold Comfort Farm; the beds recur again on p.140 ("the sprawling hours among the strawberry beds") and even again on p.501 ("the young Charles delirious with summer among the strawberry beds" etc.).

A great deal of what Mr Brent writes is well-written, sensitive, perceptive; it is a pity he should spoil the book, both in this way, and by setting up straw men to demolish, and by suggesting mysteries where they hardly exist in order to overemphasize Charles's achievements. To

refer to Charles as "the hearty outdoor dullard of legend" makes one curious as to what reputable biographer ever suggested he was a dullard. To refer to Cuvier as enigmatic, or Lamarck as brilliant but enigmatic hardly does justice to their biographers, let alone the men themselves.

Equally, in the opposite direction, Charles Darwin did so much so well that he does not need to have ascribed to him ideas which he took from others. His vision of the Unity of Nature (p.289) was a commonplace to his grandfather, as were the ideas of trees as compound animals (p.317), sensitive plants as furthering the analogy between animals and plants (p.308) and the female bosom as an object of special interest (p.319), even, to Erasmus Darwin and others, the origin of the curve of beauty.

Except in dealing with the Galapagos Islands and Darwin's finches, which have been too well written-up to allow serious mistakes, Mr Brent hardly touches without error the actual science which Darwin so avidly investigated and extended. Amphioxus is tropical only if Plymouth is too. Megatherium appears on p.156 as "an enormous forerunner of the giant sloth" and on p.198 as "the prehistoric armadillo" - in fact it was one of the giant sloths and not a precursor of anything. The "genus Brachipoda" (p.403) is a hopeless misnomer, as is the "species Canidae" (p.472), and the cirripedes had not been molluscs since Lamarck (1818). Mr Brent has no patience with the mere details of natural history, like other authors I have reviewed recently, yet to Darwin they were the absolute basis of his science. It is not surprising that Mr Brent cannot really understand why Darwin laboured so long at his barnacles, and has to put it down to Darwin's character in the end.

It is clear from Mr Brent's references to sexual selection (p.480) that he has no more understood the present standing of that topic than Gertrude Himmelfarb understood the present standing of natural selection. To comment on sexual selection that the exercise of volition by a female

... muddled the simplicity of the original vision. It was an element which conflicted with the impersonal logic of a selection process that derived only from the interaction of organism and environment....

is to show that what fascinates Mr Brent is ideas only (not their relevance to the actual world which is what fascinates a scientist). For him, natural selection "has become a staple of the everyday rhetoric through which we now define ourselves" (p.509) and it is his lack of knowledge of actual

work on natural selection that enables him to repeat the old cliché. What he calls the underlying logic of evolutionary theory "seems to say no more than that survivors survive". This hoary fallacy has been refuted many times, but he does not say so.

Mr Brent must surely have a considerable readership; his abilities in his own line are outstanding. The present book should be asked for as "the latest Peter Brent", rather than as a successful study of Darwin. No scientist need bother with it.

#### Rare air of motion

R. Hide

Dynamics of the Upper Atmosphere. By Susumo Kato. Pp.233. ISBN 90-277-1132-1. (Reidel: 1980.) Dfl. 57, \$29.95.

TECHNIQUES for investigating high-level atmospheric motions have advanced considerably over the past 20 years, with the introduction of rockets, satellites and high-powered radar on the observational side, and the advent of computers for the analysis of data and their theoretical interpretation in terms of basic physical processes.

Professor Sato's monograph — the first in a series, Developments in Earth and Planetary Sciences, stressing Japanese work but written in English - is a mathematically orientated introduction to the study of these motions and it reflects not only the author's main research interests but also (I imagine) his activities as a teacher of applied mathematics. The book deals in a straightforward and fairly standard way with the basic equations of dynamics, thermodynamics and electrodynamics applied to the atmosphere. These equations are used to describe the main properties of acoustic gravity waves and atmospheric tides and their manifestation in observations of the ionosphere. The presentation is strongly slanted towards those who are primarily interested in mathematical aspects of atmospheric wave propagation but many observational data are given in this profusely illustrated book, with its 106 diagrams and many tables.

Most atmospheric physicists would find something useful in the book, but it is possibly too narrow and, in parts, too detailed to be useful as an introductory text. The standard of English leaves much to be desired in places but this can hardly be blamed on the author, who should have been better served by his publisher.

## News from the petroleum geologists

J.R.V. Brooks

Petroleum Geology of the Continental Shelf of North-West Europe, 1981. Edited by L.V. Illing and G.D. Hobson. Pp.521. ISBN 0-85501-656-6. (Heyden & Son: 1981.) £47, \$113.

It is now some 16 years since the first discovery of offshore gas in UK waters, and 13 years since the first commercial discovery of oil. In the period from 1964 to the present nearly 1,800 wells have been drilled.

To those involved in exploration and in the production of oil and gas these have been, and still are, exciting times filled with geological surprises. But to many geologists — nearly a generation of them the scientific results of drilling have not been easily available, and it is increasingly apparent that universities schools - do not have the finances to purchase the data that now exist. Study of the geology of the UK and continental landmass of Western Europe gives only a partial picture of the total geology and geological history of the area. But when this is linked to what is now known about the North Sea Basins and other offshore areas, a more complete and meaningful picture emerges. From a teaching point of view, and to large numbers of geologists in non-oil areas, it is important that this new information becomes incorporated into the present state of knowledge.

Up-to-date data are hard to come by, but from time to time the industry holds a conference during which current views are aired and papers on exploration and proven fields published. The first conference on the petroleum geology of the continental shelf of North-West Europe was held in 1974, and the second in 1980 in London; it is the proceedings of the 1980 meeting which form the contents of the volume reviewed here.

The number (46) and range of papers presented is great; they are grouped into four main categories covering regional aspects of geology, technological developments, stratigraphy, and selected oil and gas fields. In some cases the opportunity has been taken to update material presented at the 1974 conference, but the majority of papers record more recent and current work, and present previously unpublished data.

Certain contributions were specially commissioned by the conference committee, notably those on temperature and thermal gradients in the North Sea, the regional seismic maps of the North Sea, and the subcrop map of the mid Mesozoic unconformity, the latter providing a particularly useful overview.

Clearly one cannot mention every single contribution and all of them are worthy of study, but there are a number of more significant papers that represent milestones

in exploration activity. Of these, the Brae field is as near as we have come to finding a stratigraphic accumulation of oil and its discovery has led to a search for further accumulations of this type. The discovery of the Frigg field is perhaps a unique example of a sedimentary unit which can be readily identified on a seismic section and might be described as a seismic/structural accumulation. In fact it is described as a preserved deep sea fan.

The largest discovery of oil onshore, made in 1973 at Wytch Farm, set off renewed interest in landward hydrocarbon exploration, which is currently being sustained. The results of this discovery have had considerable geological implications for exploration elsewhere in the UK, and the paper on Wytch Farm sets out the results and regional setting of the discovery.

Each of the papers in the volume represents recent results of exploration activity and might be considered as highlights of the book, published as they are for the first time. But the regional and field evaluations also serve to give the technical reader a wide overview of current hydrocarbon activity.

Such is the vast range and wealth of geology presented in this volume that no geologist, particularly those whose task it is to teach the subject, should be without a copy. Sadly, however, its cost may preclude the sort of distribution its contents deserve.

J.R.V. Brooks is Head of the Geology and Geophysics Branch of the Petroleum Engineering Division, Department of Energy, London.

# Greater clarity in lens biology

Christine Slingsby

Molecular and Cellular Biology of the Eye Lens. Edited by Hans Bloemendal. Pp.469. ISBN 0-471-05171-3. (Wiley: 1981.) £50.65, \$91.15.

PROGRESS in eye lens research, whilst resulting in a greater understanding of the organelle itself and its diseases, may also lead to discoveries in areas of more general interest. In his selection of ten contributions for this book, Professor Bloemendal has placed emphasis on the growing interest in cytoskeletal structures, as the role they play in controlling and maintaining cell shapes can be well observed in lens cells. To this end, the chapter by Lucio Benedetti et al. is

R. Hide is at the Geophysical Fluid Dynamics Laboratory of the Meteorological Office, Bracknell, Berkshire.

outstanding as a comprehensive yet coherent review of the biochemical, structural and physiological aspects of lens membranes in association with cytoskeletal filaments. By treating this aspect of lens cellular biology in the context of what is known from other organelles, the authors make obvious the advantages of this system and indicate promising areas for further research. The way forward is further underlined by Ramaekers and Bloemendal when they argue the case of the influence of the cytoskeleton on lens cell differentiation, bringing to call many exquisite illustrations.

The book makes clear the many advantages in studying this simple one-type cellular organ and it is not surprising that many people have spent time in characterizing crystallins, the lens structural proteins. These turn out to be not at all simple, but thankfully one book can only produce one classification system; a consistent usage here has led to a reasonable degree of coherence among the different authors. This classification of crystallins, complex though it must be, is where much of lens molecular biology begins and ends. It is thus a pity that where further explorations of molecular structures have been attempted, such as those resulting in a proposed model for the quaternary structure of a-crystallin, they are barely mentioned. However, there is an excellent chapter by Wilfried de Jong in which genetic relationships among crystallins are inferred from recently obtained amino acid sequences. By surveying the variability of lens crystallins throughout the animal kingdom and unearthing some obscure information relating to the functions of these diverse lenses, de Jong has produced a valuable essay on lens evolution.

In many of the chapters considerable space is given to experimental procedures and in parts this becomes an intrusion, especially when only the contributors' data are covered. In other areas the findings of all investigators and all points of view are discussed but with no synthesis; hence large tracts are unreadable. Not so, however, is the chapter by John Harding on the question of cataract research, in which he challenges most of the conventional cataract hypotheses by discussing the assumptions and contradicting the experimental data on which they are based. As a consequence, he strikes out a large body of lens research, thus rendering the book considerably shorter than it otherwise could have been.

The heroine of this book is the lens itself: the molecular story of its refractile transparency is still untold. But by presenting the background to important questions, the book can be recommended to anyone who wishes to look for the answers.

Christine Slingsby is at Birkbeck College, University of London.

# Australia's biogeographical development

Peter D. Moore

Ecological Biogeography of Australia. Edited by Allen Keast. Three volume set, pp. 2,182. ISBN 90-6193-092-8. (Dr W. Junk: 1981.) Dfl. 950, \$495.

THIS is an impressive work by any standards, even those of the publishing house of Dr W. Junk, which is renowned for its quality of production of specialized texts. Now, three volumes replace the previous book in the series dealing with Australian biogeography, published in 1959. It says much for the development of detailed knowledge of the Australian biota, and for the conceptual advances within biogeography as a science, that it has been necessary to rewrite and expand the original text within this time span.

The first volume deals with the evolution of the physical environment and its biota, and with the plant life of Australia; the second is largely concerned with invertebrates, fresh water biology and poikilothermic vertebrates; and the third covers homeothermic vertebrates, including man.

The development of the Australian environment is one area where great advances in both theory and the accumulation of raw data have taken place in the past two decades. Much attention is therefore given in the early part of the first volume to the break-up of eastern Gondwanaland and also to climatic changes during the Tertiary. Another important advance in the past ten years has been the analysis of Quaternary deposits using pollen analysis, and an integration of these data is briefly presented by Kershaw.

An interesting chapter on fire is rather uncomfortably inserted at this point, presumably because of its relationship to floral and faunal evolution, but it would have been better placed after the vegetation descriptions which follow.

The phytosociological account of Australian vegetation by Specht has more of a taxonomic than an ecological ring to it, but has some very valuable and novel components, such as the representation of C3 plant species in the vegetation formations. Some distribution patterns of selected taxa are also discussed. Specht follows this chapter with an account of the ecophysiological aspects of the vegetation. Plant-climate interactions, particularly in relation to drought and temperature, dominate this chapter, but some attention is also given to soil nutrients and the role of fire.

There follows an unconformity in that the historical approach is reinstated for the detailed consideration of Australia's fossil flora and the development of phytogeographical regions. Again, one wonders whether a more natural sequence of topics could have been arranged. For example, Hélène Martin's detailed account of the Tertiary flora would have been better

placed adjacent to the Tertiary climate section and before that dealing with the Quaternary flora. The first volume is completed by a series of papers each dealing with a separate taxonomic group of plants, such as *Eucalyptus*, the grasses, the lichens and so on, or with particular environments, such as the high mountains or the deserts. These varied approaches provide a wealth of information on the Australian flora.

The arrangement of the second and third volumes is almost entirely taxonomic, though the emphasis is generally on the evolutionary development of the group being discussed. These specific accounts of groups are interspersed with more general overviews and reviews of such subjects as the biogeography of terrestrial invertebrates or of aquatic insects. The second volume concludes with fishes, amphibians and reptiles. The arrangement of material here, by taxonomy, leads to a certain amount of repetition between chapters, particularly those relating to habitat distribution and the history of land masses.

The final volume, concerning homeothermic vertebrates, naturally spends much time on the evolutionary development of Australia's mammals, with particular emphasis upon the relationship of marsupials to arid climates and upon the late arrival in Australia (5-4x 10° years ago) of rodents. Birds also occupy a position of prominence, and a paper by Kikkawa et al. on the biological history of the Cape York peninsula, where plant and animal interchange with New Guinea has been concentrated, is worthy of especial mention.

It is refreshing to see a work of this kind in which man can be treated not simply as an additional factor of the environment, but as an organism with a biogeographical story of his own. The prehistory, physiology and anthropology of Australia's aboriginal population gives ample opportunity for this kind of treatment. The relative importance of man's arrival, about 60,000 years ago, and climatic changes since that time upon Australia's fauna is difficult to unravel, but Norman Tindale presents a graphic summary of the evidence.

This superbly produced set of books can be criticized only in that it has attempted to cover so vast a mass of information that arrangement and editing has evidently been a problem. Systematic and subject indexes are included, the former comprehensive, but the latter rather sketchy. These volumes establish a data base and reference source upon which biogeographical research in Australia will be built for many decades to come.

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, University of London.

## Anamorph anthology

C.T. Ingold

Biology of Conidial Fungi, Vols 1 and 2. Edited by Garry T. Cole and Bryce Kendrick. Vol.1, pp.486, ISBN 0-12-179501-2; Vol.2, pp.660, ISBN 0-12-179502-0. (Academic: 1981.) Vol.1 \$49, £32.40; Vol.2 \$68.50, £45.40.

An alternative title for this work might have been All About Anamorphs, yet ten years ago this would have meant nothing to a mycologist. Now we accept a whole terminology of "morphs", much to the fore in Biology of Conidial Fungi. "Morph" is sometimes used in all its nakedness, but more usually as a termination: the teleomorph is associated with sex and meiosis; the anamorph with the asexual, conidial stage; and the holomorph is the whole fungus. The holomorph ideally is a teleomorph together with its anamorph, but it may consist of a teleomorph only, or even solely of an anamorph.

The present work deals with conidial fungi which are anamorphs of Ascomycetes or Basidiomycetes, together with forms in which the "perfect" stage is not yet known or has, perhaps, been lost in the course of evolution. The conidial types in the "lower" fungi, notably Mucorales, are not considered.

During the past decade or so Bryce Kendrick has devoted much of his abundant energy to promoting the study of conidial fungi, especially by his organization of the original Kananaskis workshop summarized in Taxonomy of Fungi Imperfecti (University of Toronto Press, 1971), and of the second in the same place devoted to the linkage of conidial anamorphs with their teleomorphs. This gave birth to the two volumes of The Whole Fungus (National Museums of Canada, 1979). Now, together with Garry Cole, a distinguished student of the fine structure of fungi, he has persuaded 35 authors from all over the world to cooperate in writing 31 articles on various aspects of conidial

The articles are grouped in seven sections: history; systematics; distribution and ecology; conidial fungi and man; ultrastructure, development, physiology and biochemistry; genetics; and techniques for investigation.

• The first section has but one article, written by Bryce Kendrick, who also provides the initial chapter of the section on

Macmillan Reference Books, London (in North America, Facts on File) have recently published *The R.A.E. Table of Earth Satellites, 1957 -1980,* compiled by D.G. King-Hele *et al.* at the Royal Aircraft Establishment. The *Table* contains a chronological list of 2,145 launches and mention of some 12,000 satellites and associated fragments, details being given as appropriate. Price is £30.

systematics. One might, perhaps, expect these contributions to be a trifle dull; but not so. All that he writes throbs with enthusiasm and makes them a joy to read. The systematics section is one of the longest (260 pages), involving discussion of Coelomycetes, conidial yeasts, dimorphism, pleomorphism, conidial fungi growing on other fungi and lichens, and relations between conidial anamorphs and their teleomorphs. Nag Raj, writing about Coelomycetes, hands down ten exacting commandments for those rash enough to tackle these difficult organisms. Hawksworth contributes over 60 pages on fungicolous fungi. Although this is somewhat of an inflated list, it directs attention to these organisms which are much in need of detailed study.

In the ecological section, the chapters by Webster and Descals on fungi from freshwater habitats, and by Lacey on aerobiology, are particularly noteworthy and call for special commendation.

There is wide coverage of the economic importance of conidial fungi in connection with parasitism of crop plants, dermatophytes attacking man, mycotoxins, food spoilage and food technology, and the possibility of using certain species in the biological control of various parasites and pests. Although the fungi that prey on nematodes may not have much potential in such control, Barron's chapter on this subject is delightful.

Ultrastructure has a good innings with an illuminating chapter by Garry Cole. Nuclear behaviour is treated by Robinow in his usual masterly way. There is an interesting article by Lemke on fungal viruses and a splendid contribution by Aronson on hyphal walls.

The only chapter in the genetics section is by Hastie. This is outstanding, a real gift to mycologists at all levels.

The whole work is a major contribution to mycology and, although inevitably lacking some coherence, should find a place in all institutions where fungi are studied.

C.T. Ingold is an Emeritus Professor in the University of London, and a former President of the British Mycological Society.

# Beyond mechanics in human reproduction

R.V.Short

Conception in the Human Female. By Robert G. Edwards. Pp.1,087. ISBN 0-12-232450-1. (Academic: 1980.) £48.50, \$116.50.

DR Edwards is to be congratulated on having produced what may well turn out to be the most influential text in the field of obstetrics and gynaecology published this century. Hitherto, these specialities have been surgically orientated, and principally concerned with the mechanical difficulties of delivering babies, repairing prolapses and treating gynaecological cancers. This they have performed well, as attested in part by the maternal and perinatal mortality statistics.

Nonetheless the time has come for the profession to rise to a new challenge. Advances in our understanding of endocrinology, infertility, contraception and gamete biology have overtaken the surgical aspects of the subject, and one hopes this textbook will serve as a basis for the training of the obstetrician/gynaecologist of the future. He or she now needs to know more about endocrinology than those in general medicine, more about male reproduction than the urologist, and needs to develop a new understanding of genetics, reproductive biology, embryology, immunology and human sexuality. It is no accident that this excellent book was written by somebody who is not medically qualified; it is time for obstetricians and gynaecologists to rise to the challenge and develop their scientific understanding in parallel with their manual skills.

Dr Edwards has obviously chosen to discuss those topics that have been of greatest concern to him in the past 18 years in Cambridge, where in collaboration with Patrick Steptoe he pioneered the technique of human in vitro fertilization against open opposition from Nobel Laureates and masterly inactivity on the part of the Research Councils. Each chapter in the book is extensively referenced, and absolutely up-to-date at the time of going to press in early 1980. It is also particularly well illustrated, using key graphs, tables, diagrams and photographs taken from the work of others, duly acknowledged. The fact that Dr Edwards has been a stimulating teacher of undergraduates in Cambridge is reflected in the text — he knows what to discuss, and how to present it in the most exciting and informative

It will be disappointing if the word "Human" in the title means that this book will be restricted to medical libraries, and the bookshelves of consultants who are able to afford it. It deserves a far wider readership. Although principally concerned with human beings, Edwards takes a broad approach, and is not inhibited from discussing the wider comparative aspects of the subject. The book is destined to become a "must" for anybody working in the general field of reproductive biology — a treasured possession. For it really is excellent.

R.V. Short is Director of the MRC Unit of Reproductive Biology, Edinburgh.

## NEW ON THE MARKET

B.O.D. system. Wheaton Instruments have introduced the 60-second B.O.D. system for determining dissolved oxygen concentrations in liquid waste samples. This system measures samples precisely in <1 min to accuracies comparable to that of the Winkler method or others using electrodes. This accuracy is maintained even if the membrane becomes fouled, and no membrane replacement is required. There is no contamination or consumption of electrodes, and no oxygen is depleted from the sample. Air calibration is accomplished without having to dry the probe. The system is supplied complete with probe, cable, a.c. line cord, and complete operating instructions, including a temperature/altitude calibration table.

Circle No. 100 on Reader Enquiry Card.

Automatic curve plotting. Designed for use with the Dianagraph chart recorder/data logger, a calculation and control package is now available from Bailey Instruments. This unit enables the Dianagraph to process data in real time. For example, when channels 1 and 2 record voltage and current respectively, they can be multiplied to plot watts on channel 3. By integrating, a printout of W h can be produced automatically on channel 4. Data of wide dynamic range can be compressed using the logarithm function; rate of change of any parameter can be plotted separately using the differentiating mode. The basic Dianagraph produces analog recorder traces and digital printouts on the same paper. Using this feature, the calculation package in the integrating mode automatically measures the area beneath any curve, and prints it out in W h or any other units.

Circle No. 101 on Reader Enquiry Card.

Stopped-flow/T-jump spectrometers. The HI-TECH SF-30 series, with the accuracy and high data processing speed of an online minicomputer, incorporates a precisely controlled temperature range of -100 to +130 (±0.1)°C. A new modular accessory, the SFL-37 cryobiochemical module, allows controlled low temperature stopped-flow/T-jump work on cryobiochemical samples prepared quickly and easily, avoiding the usual curdling or separating problems.

Circle No. 102 on Reader Enquiry Card.

Gas chromatography. The Accuspec compact GC has an externally small format, but gives high performance usually associated only with larger units. The spacious, dual column oven with forced, ducted air circulation and instrument layout allow easy, effective coupling to auxiliary instruments.

Circle No. 103 on Reader Enquiry Card.

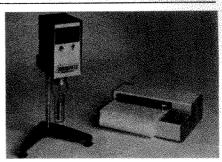

Monoclonal antibody screening. Four new monoclonal antibody screening systems, each using the ELISA assay, have been introduced by New England Nuclear. These systems provide all the components needed to screen for murine immunoglobulins, including enzyme-conjugated second antibody, colour development agent, and dilution, washing and substrate buffers. The reagents are pre-tested and optimized to prevent variables from causing unreliable results. Rapid and dramatic colour develops in the presence of positive clones. Two systems, sheep F(ab'), anti-mouse immunoglobulin and goat anti-mouse immunoglobulin, are provided with conjugated horseradish peroxidase. Circle No. 104 on Reader Enquiry Card.

Urinary amino acid controls. Human urine controls containing known levels of amino acids have been developed by Quantimetrix Medical Industries. These lyophilized controls may be reconstituted by the addition of distilled water. Disease states in which the urinary amino acid level may be increased include viral hepatitis, diabetes mellitus, hyperparathyroidism, vitamin deficiency, phenylketonuria and lead poisoning. The urinary controls also provide a reference for electrophoresis, thin-layer or column chromatography, spot testing or other amino acid analyses.

Circle No. 105 on Reader Enquiry Card.

Microcomputer interfaces. Anaspec have produced a new range of microcomputer interfaces constructed on a modular basis. These interfaces can be used with many different microcomputers, for example, the Commodore PET, Hewlett-Packard range, Apple and Superbrain. The input/output modules include analog to digital and digital to analog converters, relay closures and stepper motor controllers.

Circle No. 106 on Reader Enquiry Card.

Viscometer. The new digital viscometer from Brookfield Engineering allows continuous sensing for evaluation of time-dependent materials. The new viscometer is compatible with all Brookfield accessories and can be applied to all existing Brookfield viscosity applications. It features a large easy-to-read LED display and a 0-10-mV output signal. Optional equipment is an 8-inch chart recorder which provides a permanent record of rheological characteristics.

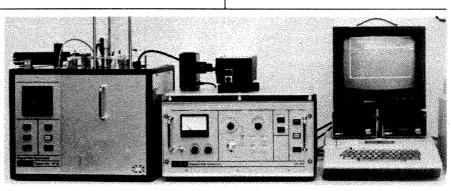

Circle No. 107 on Reader Enquiry Card.

Pyranometer solarimeter. The new model CM 11 pyranometer from F.T. Scientific Instruments uses 100 thermocouples to measure global solar radiation on a flat surface received from a complete hemisphere. Internal temperature variations are kept to a minimum and the sensitivity remains constant within ± 1% over at least a temperature range of -10°C to +40°C. In addition, two new solar integrators will accept inputs from one or two pyranometers. They integrate solar irradiance over time intervals of 10 min, 30 min, 1 h or 24 h and at the end of each preset period, a printout shows day number, real time, pyranometer calibration factor, period total and daily - or continuous total for each pyranometer.

Circle No. 108 on Reader Enquiry Card.

Particle sizer. The new Malvern Autosizer is an automatic, wide-range (10-3,000 nm) particle sizer which measures both size and diffusion coefficient. The instrument also incorporates automatic repeat measurement facilities for real-time studies of particle interactions such as agglomeration, or the effects of additives and pollutants.

Circle No. 109 on Reader Enquiry Card.

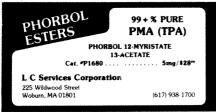

Epithelial cell culture. A new technique has been developed for culturing epithelial cells which avoids the use of y-irradiated fibroblasts as a biological substrate for the cells. The problem with the latter method is that the fibroblasts (feeder-cell) interfere biochemically with the epithelial cells. Now it is possible to culture epithelial cells without using such a substrate. The capsule of a bovine eye lens is fixed to a culture dish in such a way that epithelial cells can be cultured on it. This Epicult system is supplied by Sanbio.

Circle No. 110 on Reader Enquiry Card.

Data reduction. Five additional calculation procedures have been developed by LKB Instruments for the LKB-Wallac 1260 Multigamma counter data reduction system, based on the LKB spline program which constructs an accurate concentration curve using up to 10 standard points. Alternative data reduction methods may be selected, for example, curves of c.p.m. against concentration.

Gas mixing. A range of gas mixing equipment from Air Liquide (UK) Ltd. makes possible the production of standard mixtures of accurately known composition. The range includes a dynamic mixer supplemented with a microcomputer that is already programmed with relevant data for all gases. The operator enters the required constituents and their concentrations, and the final filling pressure, the program then checks for flammability (rejecting flammable mixtures), calculates maximum filling pressure possible (in view of any considerable gases), performs all the other necessary calculations and then prints out the final mixture composition.

Circle No. 112 on Reader Enquiry Card.

IR spectrophotometer. The new model 983 IR spectrophotomer from Perkin-Elmer provides the basic performance needed to cover almost any IR application. It provides ratio recording, a choice of resolution from 10 to 0.5 cm<sup>-1</sup>, low noise levels and a range of 180 to 5,000 cm<sup>-1</sup>. Spectra are presented on a digital printer/plotter with axis annotation, with measurement conditions printout and peak listing as options. Built-in data handling includes spectral subtraction, accumulation, digital filtering and the ability to replot in different formats.

Circle No. 113 on Reader Enquiry Card.

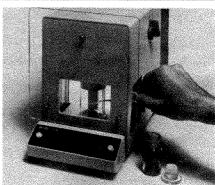

Digital display module. High-resolution vector graphics are possible using the HP 1345A digital display module from Hewlett-Packard. Intended for OEM applications with microprocessor-based instrumentation, typical applications for the module include spectrum and network analysers, waveform analysers, curve tracers, digital storage oscilloscopes and Fourier analysers. Integration of the HP 1345A into most instrument or system designs is simplified by the 16-bit binary interface which facilitates connection to 8-or 16-bit microprocessors. The advanced circuitry and electrostatic deflection CRT use < 25 W average power for increased reliability.

Circle No. 114 on Reader Enquiry Card.

Zippette dispensers. The range of Zippette dispensers from Jencons (Scientific) Ltd... has been extended by the addition of two new safety models, the 2.5-m1 and large capacity 100-m1 dispensers. Each model is simply adjusted to deliver a selected amount by turning a plastic adjuster knob against a non-fading, anti-scratch graduation. These dispensers can be used with acids and other aggressive liquids, as well as with organic solvents, and the entire dispenser can be autoclaved. The Zippette has no projecting glass valve assembly, no exposed glass syringe, and the inlet/outlet glass valve assembly is contained in a simple unit just below the screw neck in the reservoir bottle itself. This protects the operator in the event of a damaged valve. Circle No. 115 on Reader Enquiry Card.

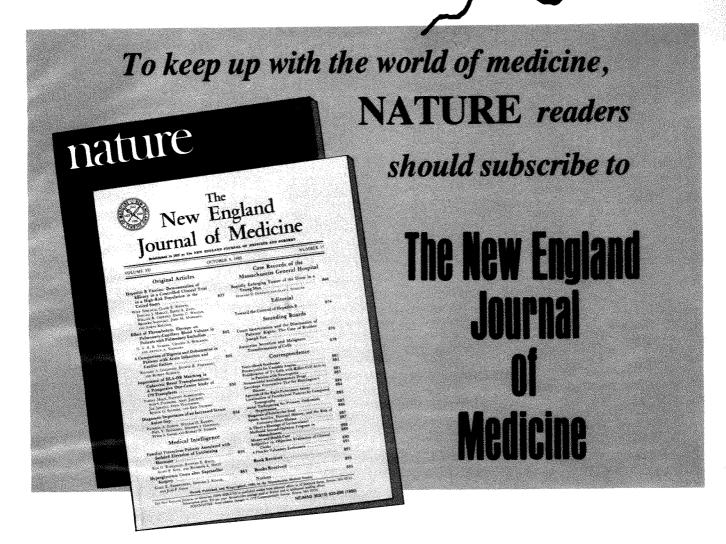

Fibre optic inspection system. A bulletin from Dolan-Jenner Industries describes a new fibre optic inspection system which provides virtually cold, high-intensity illumination and selective magnification from  $\times 2$  to  $\times 9$  for on-line inspection requirements. The model 370 features a lightweight illuminator source and a series of  $\times 2$ ,  $\times 3$  and  $\times 4$  magnifiers which can be used individually or stacked for desired magnifications. A fibre optic annular head transmits cool light for shadow-free illumination. The system is designed for inspection of microcomponents assembly detail, high-density solder connections, and low-magnification medical tissue examination. The compact illuminator housing will not exceed 80°F during continuous use and a 30-W quartz-halogen lamp provides a maximum of  $28.3 \times 10^3 \text{ W}$ cm-1 illumination.

Circle No. 116 on Reader Enquiry Card.

Electronic ultramicrobalance. The UM3 electronic ultramicrobalance from Mettler Instrument Corporation, intended for use in analytical laboratories, has a broad 1-15-mg electrical range, capacity of 3,005 mg and a readability of 0.1 µg. The balance features an easy-to-read digital display and built-in weight set specially protected against dirt and premature wear. Options include quick elimination of pan oscillations and automatic calibration. In addition, automatic transfer of weight values to a printer is possible using the Mettler 03 Data Output coupled with the UM3.

## SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.

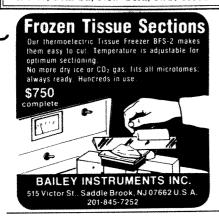

A varied range available. All simple to operate.

SINGER INSTRUMENT CO. LTD., Treborough Lodge, Roadwater, Somerset.

## AUTHORS WANTED BY N.Y. PUBLISHER

A well-known New York subsidy book publisher is searching for manuscripts worthy of publication. Fiction, non-fiction, poetry, juveniles, travel, scientific, specialized and even controversial subjects will be considered. If you have a book-length manuscript ready for publication (or are still working on it), and would like more information and a free booklet, please write:

Vantage Press, Dept. D-69
516 W. 34th St., New York, N.Y. 10001

Sample processing. The new universal computing sample-processing system from Hamilton, the Microlab 2000, is intended for liquid transfer in the clinical laboratory, including pipetting and diluting of samples. The Microlab 2000 is accurate even for samples as small as  $5 \mu l$  and reagent volumes up to 1 ml. The sample rack holds up to 500 tubes which may be thermostated and sealed, with up to 10

reagents in an adjacent rack containing four individually controlled magnetic stirrers. The unit also has a built-in wash station to minimize carry-over by washing the delivery tip both inside and out, and an integrated liquid detector will automatically set the depth of immersion of the pick-up tip to the minimum consistent with the volume to be aspirated. A disk-driven computer allows setting and control of all aspects of volume, positioning and sequence of operation; a print-out informs the user of operating conditions, working parameters and results.

Circle No. 119 on Reader Enquiry Card.

Capillary tubing. Precision 'thick septum theta' style borosilicate glass capillaries for the production of micropipette electrodes are available from W-P Instruments. This capillary tubing offers the advantages of better cell impalements due to a natural 'self-bevelling' spear-point tip, very low resistance when used as a single microelectrode and double microelectrodes with low trans-tip coupling. These capillaries are available with a standard 1.5 mm outside diameter.

Circle No. 120 on Reader Enquiry Card.

Photoelastic modulators. International announces the new PEM-80 series I and II photoelastic modulators. These feature a single control unit for multiple modulator heads covering the visible to UV range (series I) and the IR to far IR range (series II). Only low driving power is required (maximum 50 V) to obtain half-wavelength retardation, even in the far IR. The PEM-80 has an optical crystal/transducer assembly which resonates at different frequencies from 20 to 100 kHz depending on the modulator head. In turn, the periodic strain induced in the crystal causes a relative retardation between the two polarization components of a transmitted light beam. Photoelastic modulators are widely used in circular and linear dichroism measurements, spectropolarimetry, strain measurements and light modulation.

Circle No. 121 on Reader Enquiry Card.

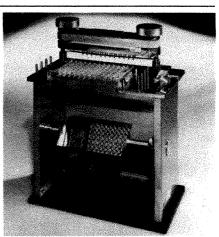

Monitoring of ATP release. A dual-sample lumi-aggregation instrument capable of simultaneously monitoring both platelet aggregation and ATP secretion on each of two samples is now available from Payton Associates. Platelet aggregation is measured photometrically while ATP release is determined by the firefly luciferin-luciferase reaction; curves are recorded on two dual-channel strip-chart recorders. Stirring speed and temperature are adjustable and continuously indicated. The 0.5-ml sample volume can be preheated in the incubation wells provided. Circle No. 122 on Reader Enquiry Card.

Capillary columns. The development of a new deactivation technique now enables WCOT glass capillary columns from Nanosep to be used at higher temperatures, considerably increasing the range of solutions which can be analysed. Operating temperatures > 300°C with minimum bleeding, and a more stable column makes possible the analysis of high-boiling point amines and phenols.

Circle No. 123 on Reader Enquiry Card.

Data logger. Columbus Instruments offer in kit form a 16-channel  $\pm 0.012\%$  accuracy (12 bits) professional data logger for scientific and industrial use. The kit model DL-1001 is based on Rockwell's AIM-65 computer expanded by 16-channel, 12-bit accuracy analog-to-digital converter, and has a calendar/clock for timing of printing intervals, etc. Voltage input ranges can be set to  $\pm 10V$ ,  $\pm 5V$  or 0 to  $\pm 10V$ . Conversion time of analog-to-digital converter is  $25\mu s$  per channel.

Circle No. 124 on Reader Enquiry Card.

Cell harvester. A compact, flexible apparatus for the rapid harvesting of cell cultures labelled with radioactive isotopes has been introduced by Uniscience Ltd. Its major advantages are the elimination of plastic tubing, economical use of filter paper, a special mirror for control of all harvesting procedures and the fact that one valve regulates flow of washing liquid. This apparatus harvests 24-h cultures simultaneously from a microtitration plate.

#### **UNIVERSITY OF** LONDON

#### INSTITUTE OF NEUROLOGY NATIONAL HOSPITAL Queen Square, London WC1 RESEARCH ASSISTANT

required for multi-disciplinary project to study modification of differentiation and proliferation of astrocytes by humoral agents. years at starting salary of £6,252 including London Weighting.

Background in biochemistry or cell biology essential.

Applications with CV and names Applications with CV and names of 2 referees to the Secretary at the above address. Telephone enquiries to Mr D G T Thomas, Consultant Neurosurgeon, 837 3611 Ext 298.

#### JOHN INNES INSTITUTE

#### CELLULAR AND **DEVELOPMENT BIOLOGIST**

Applications are invited for a post of Head of Department which becomes vacant on the retirement of Professor R W Horne. The work of the department centres on plant ultrastructural cell biology (including advanced techniques of computerised image analysis in electron microscopy), cell physiology (including origins of intracellular gradients), the biosynthesis and organisation of plant cell organelles and walls, and proto-plast studies in the context of plant genetic development and engineering.

The Institute is affiliated with the University of East Anglia and is supported by a Grant-in-Aid from the Agricultural Research Council.

Appointment will be at the grade of Senior Principal Scientific Officer (Salary scale £14,329 to £17,418 per annum); non-contributory pension

Further details of the post can be obtained from The Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH to whom applications, including a Curriculum vitue and names of three referees should also be sent.

Closing date 26 February 1982 (101)A

#### IMMUTRON INC.

#### ALLERGY RESEARCH

Positions are now open for Immunochemists (PhD) in the following areas: allergen specific IgE, basophil histamine release, allergen qulaity control and standaridization.

Candidates should have a strong background in at least one of these

Send CV to Irene B Haydik MD, Immutron Inc., Monrovia Ave, Newport Beach, Ca92663 (NW171)A

#### RESEARCH POSITION

If you are a graduate in physics, biochemistry or engineering and would like to work with me in USA in scientific instruments, please write or 'phone me.

Dr Norman A de Bruyne FRS, Chairman of the Board. Address until 6 Jan 1982, Techne Ltd. Duxford, Cambridge, England CB2 4PZ, 0223 832109. Address after 6 Jan, Techne Inc, 3700 Brunswick Pike, Princeton, NJ 08540 USA, (609) 452 9275. (NW180)A

#### THE SALK INSTITUTE **POSTDOCTORAL** POSITION

for cellular immunologist interested in autoimmune disease. Position involves study of the immune response to acetylcholine receptor in vivo and in vitro in experimental autoimmune myasthenia gravis.

Send curriculum vitae and three letters of reference to: Dr Jon Lindstrom, Salk Institute for Bio-logical Studies, PO Box 85800, San (NW177)A Diego, CA 92138.

#### UNIVERSITY OF HONG KONG LECTURESHIP IN **PHYSIOLOGY**

(Re-advertisement)

Applications are invited for a Lectureship in Physiology. appointee will be required to participate in the teaching of physiology to dental and medical students. Applicants with higher degrees in Physiology or medical degrees will be given preference. Applicants should have some research and teaching experience and a special interest in Cardiovascular Physiology.

nnual salary (superannuable) is: HK\$112,980×7,620 — 128,220 BAR 135,840×7,620 — 173,940 — 181,500 — 189,060 (£1 = HK\$11.10 approx). Starting salary will depend on qualifications and experience. A medically-qualified appointee who just completed his preregistration year will be appointed as a Lecturer at the minimum point of the scale.

At current rates, salaries tax will not exceed 15% of gross income. Housing benefits at a rental of 71/2 % of salary, education allowance, leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Appointments Unit, Secretary's Office, University of Hong Kong, Hong Kong.

The closing date for applications is 31 January 1982. (086)A

If you are knowledgeable about how libraries in the United States purchase periodicals, if you are familiar with advances in scientific research, if you are prepared to travel to Boston, Philadelphia, Washington, D.C., Baltimore, Chicago, New York and environs over a four-month period, consider applying

# **Travelling Sales Position** nature

The New York office of Nature seeks a qualified individual to solicit subscriptions from libraries and other institutions on the East Coast and in the Midwest. Travel will begin early in 1982 and continue for four months only. Travel expenses will be covered by Nature and employment with the company beyond the four-month period is possible.

Send your résumé, a letter stating your qualifications and your salary requirements to:

Nature, Box // NW183 15 East 26th Street, New York, New (NW183)A York 10010.

#### **INSTITUT FÜR MOLEKULARBIOLOGIE UNIVERSITÄT ESSEN** POSTDOCTORAL RESEARCH SCIENTIST

required for a two to four year projekt to investigate gene expression of adenovirus hostrange mutants.

The salary will be according to German BAT II a (about DM 40 -45000).

Candidates with research experience should send application including curriculum vitae etc. to:

Professor Dr H. Schulte Holthausen Institut für Molekularbiologie (Tumorforschung) Universitätsklinikum Essen - GHS Hufelandstraße 55 D-4300 Essen 1 (West Germany).

(W543)A

ANATOMY Department Head. The Purdue University School of Veterinary Medicine invites nominations and applications for the position of Head of the Department of Veterinary Anatomy. Candidates must a Doctoral Degree in an Anatomical Science and in Medicine or Veterinary Medicine. Strong research and teaching capabilities are required and administrative experience is desirable. Applications and nominations will be accepted through March 1, 1982. Applicants should submit a résumé and the names and addresses of three references to Dr Billy E Hooper, School of Veterinary Medicine, Purdue University, Lafayette, Indiana, 47907. An Equal Opportunity/ Affirmative Action Employer. (NW182)A

ASSISTANT/Associate Professor. Must have research interest in cellular and molecular aspects of hostparasite interaction. Postdoctorial experience in microbial physiology, molecular genetics, immunology, virology, or pathogenic organisms required. Teaching commitment in medical microbiology and graduate courses required. Closing date 15 February 1982. Send curriculum vitae, description of professional aspirations, and names of three referees to Dr Byron Burlingham, Department of Microbiology, School of Medicine, East Carolina University, Greenville, NC 27834. An Equal Opportunity through Affirmative Action ive Action (NW175)A Employer.

#### MEDICAL COLLEGE OF WISCONSIN DEPARTMENT OF

#### BIOCHEMISTRY **POSTDOCTORAL RESEARCH POSITION**

Available from January 1982 to study receptors for human and mouse interferons. The position is supported for two years by a grant from the American Cancer Society. The salary is up to \$16,000, depending on qualifications, with a cost of living increase for the second year. Experimental methods include cell culture, interferon assays, membrane isolation, separation and analysis of glycoproteins and glycopeptides, analysis of carbohydrate composition and structure. The position is suitable for a person with PhD or equivalent training in either biochemistry or cell biology. Experience in some of the method

Interested persons whould send applications, with résumé and names of three referees, to: Dr Helmut Ankel, Department of Blochemistry, Medical College of Wisconsin, 8701 Watertown Plank Road, Milwaukee, WI 53226. An Equal Opportunity/ Affirmative Action Employer.

ologies listed would be desirable.

(NW184)A

#### THE UNIVERSITY OF TEXAS AT ARLINGTON **CARBONATE PETROLOGIST**

The Department of Geology invites applications for a Tenure-Track or Tenured faculty position in carbonate petrology beginning fall 1982. Level of appointment and salary negotiable. A PhD and demonstrated research ability area required. Particular research interests could range from ancient/modern environmental analog studies to diagenetic/geo-chemical research. The successful applicant will be expected to teach graduate and undergraduate courses and supervise thesis research in his or her speciality, participate in the department's introductory- and general-geology teaching programs, and establish a vigorous research program leading to publications.

A résumé, 3 letters of recommendation and reprints of publications should be sent to Dr C I Smith, Chairman, Department of Geology, Box 19049, University of Texas, Arlington, Texas, 76019, by Feb 15, 1982. UTA is an equal-opportunity/affirmative-action employer. (NW186)A

#### **WELSH NATIONAL** SCHOOL OF MEDICINE

#### (UNIVERSITY OF WALES)

DEPARTMENT OF MEDICINE

#### **TECHNICIAN**

Applications are invited for the post of technician in the above Department at Heath Park, Cardiff. The post, which is initially for 2 years, involves laboratory work in the area of hypothalomic control of anterior pituitary gland function. Experience in protein chemistry for the separation, purification, identification and radiolabelling of peptides would be advantageous.

Salary on the scale for University Technical Staff Grade 4 — (£5,284 — £6,078 per annum); starting point for suitably qualified candidates could be up to £5,594 per annum.

Application form and further particulars (quoting Ref No M6/77) available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (Tel: Cardiff 755944 Ext 2296). Closing date for application 11th January, 1982. (089)A

CELLULAR PHYSIOLOGIST urgently needed. Teaching and research experience emphasized. For partipation in current work on cell culture of transformed cells. Please apply to the Chairman, Physiology Department, Ponce School of Medicine, P.O. Box 7004, Ponce, PR 00732 U.S.A. (NW150)A

#### DERBYSHIRE AREA **HEALTH AUTHORITY** CENTRAL DISTRICT

Derby City Hospital, Uttoxeter Road, Derby DE3 3NE

#### SCIENTIFIC OFFICER

Oncology Research Laboratory. Post doctoral Scientist required to join a small group undertaking research on the immunological aspects of Patients with malignant diseases. Applicants should have post-graduate experience in tumour immunology and cell cuture techniques and faimilarity with the techniques for production of mono-clonal antibodies for clinical use would be an advantage. The appointment is for 3-5 years in the first instance. Salary within the Scientific Officer (Whitley Council) scale.

Interested Applicants are advised to discuss this vacancy with Dr L C Shah, Tel (0332) 40131 ext 560.

Applications with full Curriculum Vitae and two Referees to Sector Administrator by 22nd January, 1982. Ref No 561. (103)A

#### **COLLEGE OF ENGINEERING AND** APPLIED SCIENCE

The University of Wisconsin-Milwaukee invites applications and nominations for the position of Dean of the College of Engineering and Applied Science. The University, with 27,000 students, is one of two doctoral level campuses in the University of Wisconsin System with a strong emphasis on graduate education and research. UWM is located in the heart of the state's largest metropolitan area and the center of its manufacturing and business enterprise.

The College of Engineering and Applied Science has five departments: Civil Engineering, Electrical Engineering and Computer Science, Industrial and Systems Engineering, Materials Engineering, and Mechanical Engineering, offering programs leading to bachelor through doctoral degrees.

The Dean is responsible for administrative leadership of the College. Duties include the continuing development of ongoing research programs, liaison with the industrial community, and promotion of continuing professional education programs.

Candidates should have a doctoral degree in engineering or in an applied science or demonstrated equivalent, and qualifications for a tenured faculty appointment in one of the departments of the College. The position will be available by the Summer of 1982.

All nominations and applications for the position (including résumé and the names of at least three references) should be postmarked by March 1, 1982, to: Dr Robert C Eidt, Chairperson, Search and Screen Committee, The University of Wisconsin-Milwaukee, Department of Geography, Milwaukee WI 53201.

An Equal Opportunity/Affirmative Action Employer. (NW159)A

#### **UNIVERSITY OF** SOUTH FLORIDA

DEPARTMENT OF BIOLOGY The Department anticipates TWO TENURE-EARNING **FACULTY POSITIONS** 

at the assistant professor level commencing August, 1982. These are: 1) an animal virologist; 2) a comparative physiologist with an interest in the lower vertebrates. A PhD is required and post-doctoral experience is preferred.

Applicants should submit a curriculum vitae and statement of research interests and should solicit three letters of recommendation to be sent to: Chairman, Search Committee, Department of Biology, University of South Florida, Tampa 33620. Deadline for submission is 15 February, 1982. The University of South Florida is an affirmative action, equal opportunity employer, and applications from women and minority individuals are encouraged.
(NW178)A

#### UNIVERSITY OF PAPUA NEW GUINEA

Applications are invited for the post of

## PROFESSOR OF CHEMISTRY

The appointee will be the Academic Head of Department, and will be eligible to be elected as Chairman (Administrative Head). As such, applicants should have wide capabilities and extensive experience in both teaching and research. The new Professor will be expected to contribute significantly to the research of the Department and should have wide research interests. Present research in the Department concentrates on the applications of Chemistry to development in Papua New Guinea.

Fields of interest include: chemical education; coordination chemistry; environmental and analytical chemistry; food chemistry; marine chemistry; natural products; phytochemistry of medicinal plants; and structural chemistry. The research interests of the Professor need not be confined to these areas, but he/she should be willing to apply his/her research to the needs of the country. A major responsibility of the Department is in undergraduate teaching. This includes relatively elementary service teaching, but also more advanced courses for Chemistry and other Science Students.

Applicants should also have a strong interest in the problems of teaching chemistry in Papua New Guinea at all levels covered in the University. The Department is committed to the training of National Academics and a significant contribution will be expected in this area of advanced training. Previous experience of teaching and research in a developing country in a tropical environment will be considered an advantage.

Salary: K 21,295 pa (£1 sterling = K 1.27). Three-year contract; gratuity; support for approved research; rent-free accommodation; family passages; baggage allowance; leave fares after 18 months service; education subsidies; salary continuation scheme to cover extended illness or disability.

Applicants who wish to arrange secondment from their home institutions will be welcomed. Detailed applications (2 copies), including a curriculum vitae, a recent small photograph and naming 3 referees, should be sent to the Assistant Secretary (Staffing), University of Papua New Guinea, Box 4820, University PO, Papua New Guinea to arrive no later than 31 January 1982.

Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 10 Spring Gardens, London SW1A 2BN. Further details are available from either address. (093)A

## UNIVERSITY OF ARIZONA

MULTIPLE MIRROR TELESCOPE OBSERVATORY

# MMT INSTRUMENT SPECIALIST

We invite applications for a vacant position of Instrument Specialist at the Multiple Mirror Telescope in Arizona. The MMT is a telescope of highly novel design largely devoted to state of the art optical and infrared astronomical observations. The instrumentation is among the most advanced and relies strongly on modern digital technology. The instrument specilist will be responsible for the installation, checkout, and operation of the facility instruments at the MMT. At the moment these consist of two spectrographs and an infrared photometer. In the future other instruments, specifically a CCD camera, will be added. The person filling this position will have as primary responsibility the care of the IR photometer. A background in infrared astronomy is therefore very desirable. Minimum academic requirement is a Bachelors degree in physics or related fields. The position requires working at the telescope location at an altitude of 8,600 feet at a two hour drive from Tucson.

Applications should be sent to Dr J M Beckers, Multiple Mirror Telescope Observatory, University of Arizona, Tucson AZ 85721 (tel. 602-626-1558) before February 15, 1982. The MMTO is a joint venture of the University of Arizona and the Smithsonian Institution. The University of Arizona is an Equal Employment Opportunity/Affirmative Action Employer. (NW179)A

# ROSWELL PARK MEMORIAL INSTITUTE MOLECULAR IMMUNOLOGY

a comprehensive cancer research center has available three-tenure track positions which are open in the Department of Molecular Immunology. The department is expanding into the areas of idiotype manipulation and recombinant DNA technology. One of the positions is at the senior, (full professor equivalent) level and two are at the junior level. No formal teaching is required at the Institute, but graduate students are available through the institutional graduate program. The candidate for the senior staff position will be consulted in the selection of the junior candidates.

Applications should be forwarded to Heinz Kohler, Chairman of the Department of Molecular Immunology, Roswell Park Memorial Institute, 666 Elm Street, Buffalo, New York 14263. An Affirmative Action/Equal Opportunity Employer. (NW170)A

#### JANSSEN PHARMACEUTICAL LIMITED

# SENIOR CLINICAL RESEARCH ASSOCIATE

To enable us to continue to expand our clinical research programme on our range of anti-fungal products, we require a science graduate, preferably with post-graduate research experience and at least two years experience working within the pharmaceutical industry industry.

The successful applicant will act as Senior Clinical Research Associate and will initiate, supervise and progress a clinical trial programme required for new developments in our anti-fungal range. The position reports directly to the Director of Clinical Research.

Energy, judgement, personality and good communication skills will be rewarded by an excellent salary (according to experience), a company car and good working conditions in the pleasant location of Marlow.

If this opportunity is of interest to you, and you would like to know more about us, please telephone or write with full Curriculum Vitae to:

Mr. M. B. Emanuel,
Director of Clinical Research,
Janssen Pharmaceutical Limited,
Janssen House,
Chapel Street,
MARLOW, Bucks.
SL7 1ET.
Tel: Marlow 71744

Last date for applications Friday 15 January, 1982.

(091)A

#### YARMOUK UNIVERSITY Irbid, Jordan

## TEACHING POSITIONS

Yarmouk University invites applications for teaching posts in the fields of specialization listed below for the academic year 1982/1983:

— Biology: (Comparative Anatomy, Molecular Biology, Plant Physiology, Virology).

- Physics: (Solid State Physics (Experimental), Quantum Electronics, Astronomy (Observational)).

Candidates should hold a PhD. Annual Salary ranges from \$16,000 to \$28,000 for nine months service. Jordanian income tax nominal. Fringe benefits include medical and life insurance, furnished housing for reasonable rent, and travel air tickets for appointee and family (spouse and children under eighteen). Extra remuneration is paid for summer teaching. A model school is available with nursery section and two programs of instruction, one for Arabic speaking children and the other for English speaking children.

Complete dossier (transcript, three letters of reference, copies of degrees) to be sent not later than end of January 1982, to: The Dean, Faculty of Science, Yarmouk University, Irbid, Jordan. (W541)A

# UNIVERSITY OF THE WEST INDIES Trinidad

#### Applications are invited for the post of LECTURER/ASSISTANT LECTURER IN BOTANY

in the Department of Biological Sciences. Applicants should hold a good Honours Degree in Botany and preferably have a higher degree.

Duties of appointee will include teaching undergraduate Botany courses including Plant Morphology and Anatomy and Economic Botany.

Salary scales (to be reviewed): Lecturer TT\$ 29,784 — 43,752 pa. Assistant Lecturer TT\$ 24,156 — 26,484 pa. (£l sterling = TT\$ 4,69). FSSU, Unfurnished accommodation or housing allowance. Family passages. Study and Travel Grant.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Secretary, University of the West Indies, St Augustine, Trinidad.

Applicants resident in UK should also send I copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 10 Spring Gardens, London SWIA 2BN.

Further details are available from either address. (096)A

#### **MOLECULAR BIOLOGY**

The Microbiology Department at Case Western Reserve University invites applications for several tenure-track faculty positions. Although we encourage applications from candidates with strong credentials in any area of Molecular Biology, we are especially interested in applicants who propose to study regulation of gene expression, or molecular biological aspects of virology of immunology. Experience in recombinant DNA techniques is desirable. These appointments provide excellent opportunities to develop independent research and teaching programs in an expanding medical school department. Send curriculum vitae, a statement of research and teaching interests and the names of four references to Dr. Fritz Rottman, Chairman, Department of Microbiology, Case Western Reserve University, Cleveland, Ohio 44106.

An Equal Opportunity/Affirmative Action Employer
(NW188)A

#### UNIVERSITY OF GLASGOW DEPARTMENT OF ONCOLOGY

Applications are invited for the post of RESEARCH ASSISTANT

in the Department of Oncology. The post is suitable for graduates in Biochemistry, Cell Biology or related fields. The project, supported by the Cancer Research Campaign for a period of three years, involves studies on mechanisms of tumour cell resistance to cytotoxic drugs using animal models and cultured tumour cells.

The initial salary is £5,289 per annum, plus U.S.S. benefits.

Applications with curriculum vitae and names of two professional referees should be sent to Dr S Kaye, Department of Oncology, University of Glasgow, 1, Horslethill Road, Glasgow Gl2 9LY, to arrive by 11th January, 1982. (098)A

PHYSIOLOGY Faculty Position: Assistant Professor tenure-tract position for July, 1982. An interest and post-doctoral research experience in gastrointestinal physiology, particularly in peptides of the gastrointestinal tract and their regulatory role, is preferred. Candidates will be expected to teach physiology of the digestive tract to medical students and to participate in graduate courses and to develop an independent research program. Applicants should submit curriculum vitae, reprints and statement of research interests, and teaching experience, and have three letters of recommendation sent to: Dr Robert E Forster, Chairman, Department of Physiology, School of Medicine, University of Pennyslvania, Philadelphia, Pa 19104. An equal opportunity/affirmative action employer. (NW164)A

## ICHTHYOLOGY JOB DESCRIPTION

Cornell University solicits applications for a tenure-track position, preferably an Assistant Professor, in the Section of Ecology & Systematics to begin September 1982. We seek a Systematic Ichthyologist with broad intergets in vertebrate biology and a strong research program. The successful candidate will participate in curation of the Ichthyology Collection. Teaching responsibilities include an upper-level course, and participation in the graduate program in vertebrate biology.

Applications must include a curriculum vitae, names of three references, and will be reviewed February 1, 1982. Send application to: Dr W N McFarland, Section of Ecology and Systematics, Cornell University, Ithaca, New York 14850. Cornell University is an affirmative action/equal opportunity employer.

(NW157)A

#### UNIVERSITY COLLEGE LONDON School of Medicine

#### **TECHNICIAN**

required to work with Dr R A Knight and Dr M L Snaith on immunological aspects of systems lupus erythematosus in man, in the Rayne Institute of University College Hospital.

Applicants should have experience of tissue culture, and in vitro tests of human lymphocyte function. Appointments is for two years, and the starting salary is on the third year of the MLSO scale.

Applications with a curriculum vitae and names of 2 referees should be sent to Mr Blackman, Personnel Officer, Technical Staff, University College, London WC1. (095)A

#### **MICROBIOLOGY**

Applications are invited from individuals with demonstrated excellence in microbial biochemistry or molecular biology for a tenure-track assistant professorship in the Department of Microbiology at the Medical College of Wisconsin. Applicants must have postdoctoral research training and be able to develop an independent research program, teach medical students, and instruct garduate students.

Send résumé, summary of proposed research, and names of references to: Search Committee, Department of Microbiology, Medical College of Wisconsin, PO Box 26509, Milwaukee, Wisconsin 53226. Affirmative Action/Equal Opportunity Employer.

(NW176)A

#### ANIMAL BIOCHEMIST

The Department of Agricultural Biochemistry of the University of Nebraska-Lincoln. Tenure-track assistant or associate professor. Postdoctoral experience and research interests in any area of basic biochemistry related to the growth and reproduction of domestic animals is desirable. This 12-month position, primarily in the Experimental Station, includes teaching duties. Résumé and names of three references should be sent by February 28, 1982 to: J.M. Daly, 206 Agricultural Biochemistry Hall, The University of Nebraska, Lincoln, NE 68583-0718. Phone (402) 472-2932. An Equal Opportunity/Affirmative Action Employer. (NW187)A

#### UNIVERSITY COLLEGE LONDON School of Medicine

#### 1st year POSTDOCTORAL SCIENTIST

required to work in a laboratory headed by Dr R A Knight and Dr M L Snaith on immunological dysfunction in human systemic lupus erythematosus.

The laboratory is in the Rayne Institute of University College Hospital, London.

Its main interests are in pathways of suppressor T cell generation, the role of interferons in these pathways, and on the nature of the suppressor deficit in lupus patients.

Applications should include a curriculum vitae, and the names of 2 referees, and should be sent to Dr R A Knight, Dept of Rheumatology, University College Hospital, London WC1. (094)A

#### TOXICS SCIENTIST

Ph.D. to direct technical aspects of Toxic Chemicals Program with national environmental organization in Washington, D.C. Salary competitive.

Apply in writing to: Environmental Defense Fund, 444 Park Avenue South, 9th Floor, New York, N.Y. 10016.

(NW181)A

POSTDOCTORAL position available beginning June 1, 1981 in the Developmental Biology Center, University of California, Irvine. Recent PhD required preferably in the areas of cell biology, molecular biology, developmental biology, or genetics. Research will be conducted in the laboratories of P J Bryant, J L Marsh (molecular genetics of *Drosophila* development, using molecular cloning and/or hybridomas), or R Cambell (cell behaviour and morphogenesis). The University of California is an equal opportunity/ affirmative action employer. Submit resume and brief description of research interests and experience, together with the names of three individuals willing to write on your behalf, to: Peter J Bryant, Developmental Biology Center, University of California 92717 by March 1, 1982. #### SHEFFIELD AREA **HEALTH AUTHORITY** (TEACHING)

**Royal Hallamshire** Hospital WHOLE TIME **GRADUATE NON** MEDICAL SCIENTIFIC **OFFICER** 

BSc Honours Graduate with a 2:1 Biological Science degree is required to investigate Haemostatic Mechanisms with particular emphasis on Platelet Biochemistry in patients with Renal Disease in the Department of Renal Medicine and Haematology at the Royal Hallamshire Hospital, Sheffield. This research post is funded for one year in the first instance, with possible extension to three years, at a starting salary of £5,667 per annum, depending upon experience and degree.

Applications stating age, qualifications, present and previous appointments (with dates) giving names and addresses of two referees to the Area Personnel Officer, Westbrook House, Sharrow Vale Road, Sheffield S11 8EU by 15th January 1982. (102)A

#### THE INSTITUTE FOR **ADVANCED STUDY**

will have several openings for members in theoretical physics and astrophysics for the academic year 982-83. The positions are at a postoctoral or higher level and appli-ints will be selected on the basis of neir ability to do research in the areas elementary particles, matheatical physics, astro-physics sma physics, general relativity and itistical mechanics. Preference is ven to candidates who have ceived their PhD within the last ear or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with esearchers at other institutions

Appointments are usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are acouraged to apply

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, he Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

# Training Fellowships 1982-83

The Medical Research Council's Training Fellowship scheme enables **medical and dental graduates** at any stage in their career up to and including Senior Registrar, Lecturer or equivalent levels, and science graduates with post graduate or postdoctoral experience to gain specialised research training in the biomedical field in the UK

Applications are now invited from suitably qualified candidates for awards to be taken up in the 1982-1983 academic year. Fellowships may be held for periods of from six months to three years (subject to annual review).

ELIGIBILITY REQUIREMENTS: candidates should have been ordinarily resident in the UK throughout the period of 3 years immediately preceding the application date. Graduates in medicine and dentistry: from post-registration up to Senior Registrar or equivalent academic levels. Graduates in science: PhD/DPhil (or in certain circumstances MSc plus at least 3 additional years'postgraduate experience).

TRAINING PROGRAMMES: proposals may be submitted for specialised research training or in the case of medical/dental graduates for training in a basic subject relevant to a particular clinical interest. Fellowships are also available to provide support for medical/dental graduates to attend one-year researchorientated courses leading to an MSc.

EMOLUMENTS: appropriate point, with increments, on the current NHS medical, equivalent dental or current university non-clinical lecturer scales.

Application forms are available on request from the Medical Research Council, Training Awards Group, 20 Park Crescent, London W1N 4AL (tel. 01-636 5422 ext. 448). Closing Date for receipt of applications: 28 February 1982. Late applications will Medical Research Council not be accepted.

# **MRC Celltech Fund** Research Fellowship

Kingdom is offered from October 1982. Applicants should have proven research ability in a subject in the MRC field and be below the age of 32 on 30 September 1982; there is no restriction as to nationality or domicile. Those interested should discuss their proposal with the Director of the MRC laboratory in which they wish to work.

The MRC Celltech Fund, which is administered by a subcommittee of the Council, derives its revenue from royalties payable by Celltech Ltd on sales and services based on research in MRC establishments

Further details and application forms are available from Mr. B. C. Dodd, Medical Research Council, 20 Park Crescent, London W1N 4AL. Closing date for receipt of of applications: 28th February, 1982. Late applications will not be accepted.

#### WORKSHOP

**HUMAN TUMOUR 'STEM' CELL CLONING -**2ND WORKSHOP

**IMPERIAL CANCER RESEARCH FUND** Lincoln's Inn Fields, London, WC2 March 25-26, 1982

This workshop will deal with (1) Practical (2) In Vitro drug testing and (3) Clinical aspects of these techniques. Dr S Salmon (Tucson, USA) and Dr K M Tveit (Oslo, Norway) have been invited. Participation will be limited to clinicians and scientists with practical and/or clinical experience of drug sensitivity testing.

Those wishing to contribute are invited to send details to Bridget T Hill at the above address by January 25th, 1982. For more information 'phone John Masters, 01-836 9611. (088)V

#### CONFERENCES and COURSES

#### **FEBS ADVANCED COURSES**

No.82/01. "Biomolecular Electron Microscopy (BIOMOLEM 1982)" Ulm, FRG, 25 March-3 April 1982

The course, organized by A.K. Kleinschmidt and G. Klotz, will be conducted at an advanced level covering selected methods of biomolecular electron microscopy. It will include specialized lectures, with short communications by participants, and lectures on general topics. Laboratory practical sessions will be on topics of the participant's choice, and will include electron microscopy of nucleic acids, protein and nucleoproteins, membranes and lipoproteins, and molecular studies in biological supraorganization. Course fee, including accommodation and meals: DM 600. Further info and application forms (to be returned by 1 February 1982): Dr G. Klotz, Microbiology Department, University of Ulm, D-7900 Ulm, Postfach 4066, FRG.

No.82/02. "Biochemistry and Genetics of Yeasts" Madrid, Spain, 5-24 July 1982

A course of lectures, seminars and practical work on the potentialities of yeast as a model eukaryotic system for studying enzyme regulation and gene expression. Topics: energetics, physiological inactivation of enzymes, compartmentalization and regulation, complementation and recombination, yeast transformation, and cloning of yeast genes Course fee, including accommodation and breakfast: about 35,000 ptas. Further info and applications (before 28 February 1982): Dr C Gancedo, Instituto de Enzimología del C.S.I.C., Facultad de Medicina de la Universidad Autónoma, Arzobispo Morcillo, 4, Madrid-34, Spain.

# No.82/07. "Replication of Bacterial Plasmids" Odense, Denmark, 2-18 August 1982

A laboratory course for 12 students, organized by K Nordström and S Molen, concentrating on plasmid replication and its control, plasmid partitioning at cell division and the correlation between these processes and plasmid incompatibility. The course will include a theoretical part organized as mini-symposia with short communications by participants, and a practical part introducing various techniques and experimental approaches used in plasmid research as well as in work where plasmids are used as experimental tools. The main biological material used will be *E. coli* and the plasmids R1 and ColE1. Registration fee, including accommodation: DM400. Further info and application forms (to be returned by 31 March 1982): Dr Kurt Nordström, Dept. of Molecular Biology, Odense University, Campusvej 56, DK-5230 Odense M, Denmark.

#### No.82/05. "Structure and Function of Plant Genomes' Erice, Sicily, Italy, 1-11 September 1982

course of lectures, discussions and poster presentations, for about 120 students. Main topics: Structure, organization and expression of the nuclear genome, the chloroplast genome, and the mitochondrial genome in higher plants; Biosynthesis of plant storage proteins; Genetic manipulation of higher plants; Nitrogen fixation; Molecular biology of host-pathogen interaction; Molecular biology of plant viruses. Living expenses: US\$450 approx. All participants will be expected to present a poster. Applications, with a curriculum vitae, a provisional poster abstract, and other information to aid evaluation, should be sent in duplicate to: Dr Orsola Tiboni, PO Box 202, 27100 Pavia, Italy, to arrive not later than 15 March 1982

#### No.82/04. "Structure and Metabolism of Glycoconjugates" Lille, France, 6-18 September 1982

The fee for this course, including accommodation and meals, will be FF 2000 approx. Applications should be sent by 1 April 1982 to: Professor J Montreuil, Université des Sciences et Techniques de Lille I, Laboratoire de Chimie Biologique, 59655 Villeneuve d'Ascq Cédex, France, from whom further information may be obtained. #### **INSTITUTES OF** PSYCHIATRY, NEUROLOGY AND OPTHALMOLOGY

(British Postgraduate Medical Federation, University of London)

#### MSc IN **NEUROCHEMISTRY**

This is a ONE-YEAR Course leading the degree of MSc in Neurochemistry. It offers graduates in science and medicine training in basic and applied neurochemistry. Course consists of lectures, seminars and laboratory work and, in the second and third terms, research on a neurochemical topic.

Applicants should have a First or Second Class Honours degree in Biochemistry or a cognate subject, or be medically qualified. The Course is recognsed by the Medical Research Council as an Advanced Course for the award of Training Scholarships to suitably qualified applicants.

Applications for the Academic Year October 1982 — July 1983 should be addressed to the Secretary, Course in Neurochemistry, Department of Biochemistry, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, England. (097)C

#### **TENDERS**

#### **ROYAL BOROUGH OF** KINGSTON UPON THAMES **Directorate of Education** and Recreation

#### Kingston Polytechnic

Tenders are invited for the supply of multinuclear Fourier Nuclear Magnetic Resonance Spectrometer at the Polytechnic. The general specification includes:

a) An ability to measure proton (hydrogen 1) spectra\_at a frequency between 80 MHZ and 100 MHZ;

b) Multinuclear observation capability including the ability to obtain spectra for Carbon — 13, phosphorus — 31 and nitrogen —

c) Dedicated computer, minimum capacity 16K, and software package for spectrometer control and data processing;

d) Foreground/background capability or the equivalent, for simultaneous spectrum acquisition and data processing;

e) Variable temperature operation 150°C to + and the range -150°C.

Potential tenderers should apply for tender documents and a more detailed specification to the Administration Manager, Directorate of Education and Recreation, Guildhall, Kingston upon Thames not later than 31 December, 1981. (100)T

FELLOWSHIPS continued from page xvii

#### **DEPARTMENT OF EDUCATION, DUBLIN** POST-DOCTORAL RESEARCH FELLOWSHIPS 1982/83.

Applications are invited for research fellowships in science (excluding medical and social science) and engineering tenable in any one of the following institutions in Ireland:-

University College, Dublin.

University College, Cork. University College, Galway. Trinity College, Dublin. St. Patrick's College, Maynooth.

The National Institute for Higher Education, Dublin. The National Institute for Higher Education, Limerick.

An Foras Talúntais

(The Agricultural Institute), Dublin 4.

The Institute for Industrial Research and Standards, Dublin 9.

Fellowships will be tenable for a period of two years with the possibility of an extension for a third year.

Applicants should hold the degree of PhD or have equivalent research experience. Applications will be considered from engineers or technologists with suitable industrial experience. Candidates must be under the age of 30 years and preferably under the age of 28 years on 20 March, 1982.

Appointments will be effective from a date not earlier than 1st October, 1982. The initial salary, which will depend upon qualifications and experience, will normally be within the range £5,392 to £6,081 per annum, but awards of up to £7,056 may be made in the case of engineers and technologists whose industrial experience or other special circumstances warrant it.

Full particulars of the scheme including application forms may be obtained from The Secretary, Department of Education (Headquarters Section 3), Marlboro' Street, Dublin 1, to whom applications for Fellowships should be forwarded. The latest date for the receipt of applications is 20th March, 1982. (W542)E

## DICTIONARY OF THE HISTORY OF SCIENCE

Edited by W.F. Byrnum E.J. Browne Roy Porter

# Is soon of the state of the sta

Is there a gap in your bookcase? Until now, there hasn't been a dictionary devoted exclusively to the history of scientific ideas. And however you are involved in today's scientific world, you will agree that your present work and scientific attitudes are inevitably influenced by and built on those from the past.

Science and its key doctrines – from quantum theory to genetics – are central to the modern world; yet daily it changes and develops, becomes more technical and diverse. What is needed is a reference book that enables you not only to master the past but also to keep you in touch with the theories underlying the most recent scientific and technological developments.

The Dictionary of the History of Science fills the gap.

#### Authoritative

It is the work of three editors: W.F. Bynum, E.J. Browne and Roy Porter; of ten subject editors – including Michael Hoskin, Richard Burkhardt, William Brock, Steven Shapin, Roger Smith, Eric Aiton, Roy Bhaskar, John Heilbron – and over 90 contributors, all authorities in their field. It explains the core features of Western science and their development. 700 entries, alphabetically arranged, cover such fields as astronomy, biology, chemistry and earth sciences, the historiography, philosophy and sociology of science; human sciences, mathematics, medicine and physics.

Substantial concepts such as Evolution and Light are given generous entries, while more specialized subareas like Neo-Darwinism and Light Velocity are allocated smaller amounts of space. All are cross-referenced back and forth.

#### Comprehensive

Although the Dictionary is principally concerned with the Western scientific tradition of the last 500 years, it touches, too, on the central scientific ideas of classical and medieval times, and of other cultures. In addition, it features such topics as the development of technology and clinical medicine, and of important scientific instruments like the astrolabe and the thermometer.

Our understanding of the processes of scientific discovery and change is often controversial. But however you view them, it is important that you have easy access to all the ideas you are building on today, in the most scholarly, up-to-date and comprehensive detail.

If you are searching for the missing link, the Dictionary of the History of Science is your natural selection. At this special price to subscribers to Nature, it must be!
